Our next centre was the old-fashioned town of Lauder. Hidden away among the hills it seems to have got behind the rest of the world, and many of its customs and ways belong to a bygone age. Thirlestane Castle, the seat of the Earls of Lauderdale, is close to the town. It was probably built in the seventeenth century and is of a most unusual plan, consisting of a long narrow building with four large round towers, one at each corner. Accompanying each of these round towers is the stair turret in the angle, such as is in many L plans. Between these large towers are three turrets on each side, the two centre ones enclosing staircases. This plan is quite unique. Elcho and Kelly are somewhat similar, but there the turrets are placed irregularly. The first floor contains an ante-room or hall, dining-room, drawing-room and bed rooms; and it is with these rooms that we are particularly interested, for they contain some of the finest plaster ceilings in Scotland. Pennant refers to Thirlestane Castle as having been heavily stuccoed by the Duke of Lauderdale in the time of Charles II. The work, like that at Holyrood Palace, is hand-wrought and infinitely varied in design. Each leaf is separately moulded and stuck on; in many cases the finger mark can be seen where it has been pressed into position. Some of the ceilings are rather overcrowded with ornament, though the detail is very good in itself, but the smaller ones are fine examples of this style of work. Many of the ornaments and parts of the design are almost identical with those used at Holyrood, and it is very probable that the same workmen were employed at both places.

The village church, in its quaint old kirkyard, is worth looking at. Its plan is a small Greek cross.

There are not many other architectural features in the immediate vicinity, excepting peel towers.

---

* A paper read before the Edinburgh Architectural Society on December 19th, 1900.

IONA ABBEY.

We visited Melrose Abbey one evening—not by moonlight, however. Removing our camp southwards, we next pitched at Jedburgh. This is an excellent centre for visiting the Border abbeys, being within easy distance of Melrose, Dryburgh and Kelso, and other interesting early remains, such as Edrom and Chirnside. Jedburgh itself is a delightful town, lying in its narrow valley, "the strength of Teviotdale," and almost like an English hamlet in its surroundings. Here we devoted our attention almost entirely to the Abbey, and measured the west front, including the fine Norman doorway, one of the best specimens of the period in Scotland. David I., while yet Prince of Cumbria, founded here a Priory of Canons from St. Quentin Beauvais, in 1118. In 1147 the priory was made an abbey, and it was then that the Norman portion of the present building was erected. The priories of Canonby, Dumfriesshire, and Restennet, Forfarshire, were dependencies of Jedburgh, and before the end of the twelfth century the churches of Ancrum, Longnewton, Oxnam, Eckford, Crailing, Nisbet, Hobkirk and Liddell were under it. The abbey was dedicated to the Virgin, and was richly endowed by David I. and the nobles of the district. The oldest parts of the building are the choir and west front. These are the only portions remaining of the twelfth-century building. The abbey was either set out in Norman times and not completed till later, or it was destroyed and had to be restored in the Transition style. The south doorway to the cloisters is also Norman, and there are remains of Norman transepts. The west end is Norman work to the top of the clerestory walls, above which the gable and wheel window have been added at a later period. The west doorway is a very rich specimen of late Norman work, and is very interesting as showing in its mouldings the early beginnings of the Transition style. The expedient has been here resorted to of thickening the wall at the doorway to a kind of porch, to give a feeling of depth and solidity to the front, which it needs, as the buttresses and window jambs are very shallow. The doorway jamb has contained five free shafts, between which are the usual late Norman chefron, chain-mould, and figure panels. The beginning of the dog-tooth ornament can be seen in a star-like ornament running round one of the members of the arch-mould. The porch is finished with three gablets containing niches, with trefoiled arches. The wall on each side of the west window has been divided into three panels by long detached shafts tied to the wall at intervals, but these have almost all fallen away. The stone is in a very soft condition, and in a few years the mouldings will be washed almost completely away.

We also measured the house opposite Smith's Wynd, where Queen Mary stayed while in Jedburgh, and where she suffered the fever which so nearly ended her life. The plan has been considerably altered, but the elevations are still well preserved. It is probable that the house was built after Jedburgh had been destroyed by Surrey in 1523.

Fernieherst Castle lies about two miles up the Jed, picturesquely situated above a narrow gorge and surrounded by woods. The present building was built by Andrew Ker in 1598, on the site of an older fortress, which had seen many a hard fight when the blue bonnets encountered our friends "the enemy over the border." This sixteenth-century house possesses many quaint and useful details.

Next we visited Stirling. The rock is crowded with buildings more or less interesting—the mint, the parliament hall, the chapel royal, about all of which tales more or less authentic are poured into the usually listless ear of the man in the large check tweed.

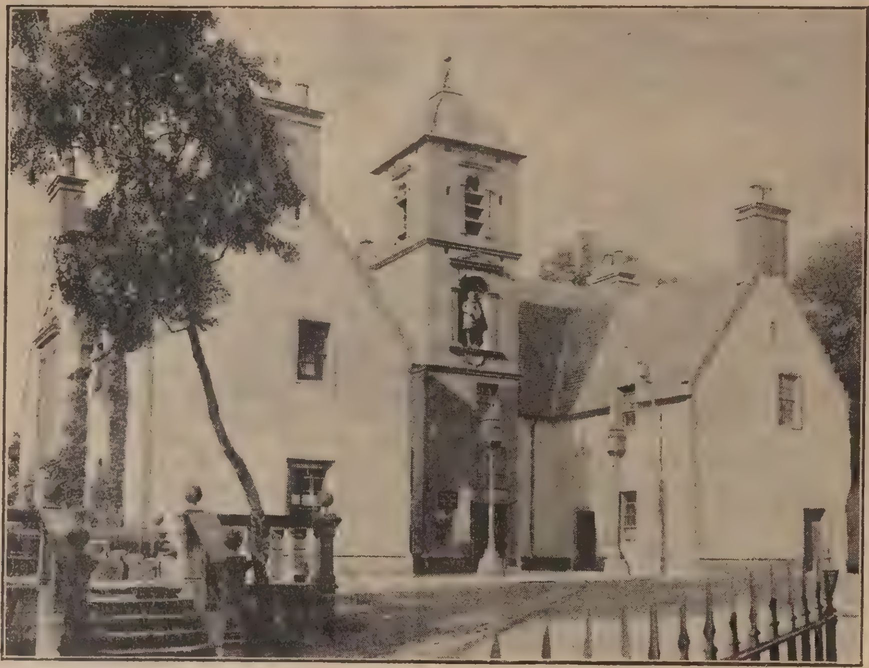
The palace itself is more curious than beautiful, though taking it as a whole it has certainly a rich and striking effect. It lies at the south-west corner of the castle rock, and surrounds a square courtyard called the Lion's Den. Lions were kept by James IV. for the amusement of his court.

The entrance to the palace is from the upper courtyard, and is on the first floor. The principal rooms are ranged round the quadrangle, each occupying the whole width of the building. Beyond the reception room is the audience chamber, and through this again are the private apartments of the king, now used as a mobilization store. On the west of the quadrangle there is a corridor leading to apartments on the south and east sides, and probably intended to communicate with future buildings on the west. The rooms on the south and east have been the salon, the dining hall, and the private apartments of the Royal Family. (I may say here that I am indebted for much of this information to Messrs. MacGibbon and Ross, in their exhaustive work on "Scottish Domestic and Castellated Architecture.") These rooms seem to have been richly decorated, probably with tapestry and wood panelling. A few panels from the ceiling of the presence chamber are preserved in the Smith Institute, Stirling, and the Antiquarian Museum, Edinburgh. They represent Scots worthies, both men and women, not beautiful, but no doubt good. Some of the designs in the spandrels of these panels are exceedingly fine. The rooms in the basement have been mostly used as cellars, and form a sort of Chinese puzzle to the bewildered but conscientious student who wishes to set off the correct angles, &c., but cannot find two parallel walls to start with. The upper floor was originally lighted with dormers behind the parapet, but these have been removed, and the present large windows cutting into the cornice substituted.

CAP, IONA ABBEY.

The exterior of the palace is interesting as being the earliest example of the introduction of the Renaissance style into Scotland. The flat, arched recesses, enriched with cusped work, have a Gothic feeling, while in the round and baluster-shaped columns, and in their caps and enrichments, we have clear evidence of the Renaissance style. The mode in which the statues are placed upon the building, set in shallow niches, is Gothic rather than Classic, but in the grotesque figures themselves there is evidently a rude attempt to copy some of the antique models. The four figures on the south side represent Scottish soldiers—one bending his cross-bow, another taking aim, a third bearing a sword, and a fourth with a fanciful shield. The other figures are coarse but bold and effective grotesques. These figures have a distinctly French feeling,

THE CLOISTERS, IONA ABBEY.



COWANE'S HOSPITAL, STIRLING.

and were probably the work of men whom James V. brought over after his marriage and stay in France. The cusped work round the arches, the Renaissance details mixed with Gothic forms, and the free use of sculpture are all features which were much in vogue in France at the time of the king's visit, and we may see in this palace an attempt to reproduce the same kind of work which he had admired at Loches and Blois. But the Renaissance work here introduced is far in advance of the style generally in use in Scotland. It was not till fifty years later that the Renaissance style became common, and then it was very inferior to that of Stirling. The square tower at the south-west corner is older than the palace, which has been built on to it so that the windows avoid it, and a staircase runs from top to bottom of the tower. The joint can still be distinctly traced where the tower meets the palace wall. It was probably a tower on the old castle wall. This outer wall is connected to it, and the style both of it and the wall is older than that of the palace. When the palace was erected the space between it and this outer wall was built over so as to form a kind of terrace at the level of the battlements which could be used either as a battery or a promenade. Indeed it seems to have been used for the former purpose when General Monk was storming the castle, as the wall behind is riddled with shot-holes.

Having completed the measuring of the palace we spent a few days taking photographs of buildings in the town. One of the best preserved of these is the Guild Hall or Cowane's Hospital, built by John Cowane in 1639 for the "Intertainment of decayed Gild Breither." It stands near Greyfriars. Close to the castle is Argyle's lodging, now used as a military hospital. It was begun in 1632 by Sir William Alexander, and completed about 1674 by the Argyle family. The town abounds in quaint old houses, crow-stepped gables, and dormers galore. Queen Mary had a house here, as usual. The Town Hall is a fine specimen of the seventeenth-century Renaissance in Scotland. But in spite of all its quaint delights, Stirling is not a pleasant place to work in—at least we found it so, and former students of the Survey seem to have had the same experience.

We were glad when we heard that our next move was to the "green lonely isle" of Iona. We travelled to Iona via the Crinan Canal and Oban, where we stayed overnight. This little island of Iona must always be full of special interest to Scotsmen. St. Columba came in 563 A.D., an exile from his native land of Ireland, to found his little colony here, and through the dark ages that followed, in spite of many interruptions, his zealous followers went through Scotland bearing the word of truth.

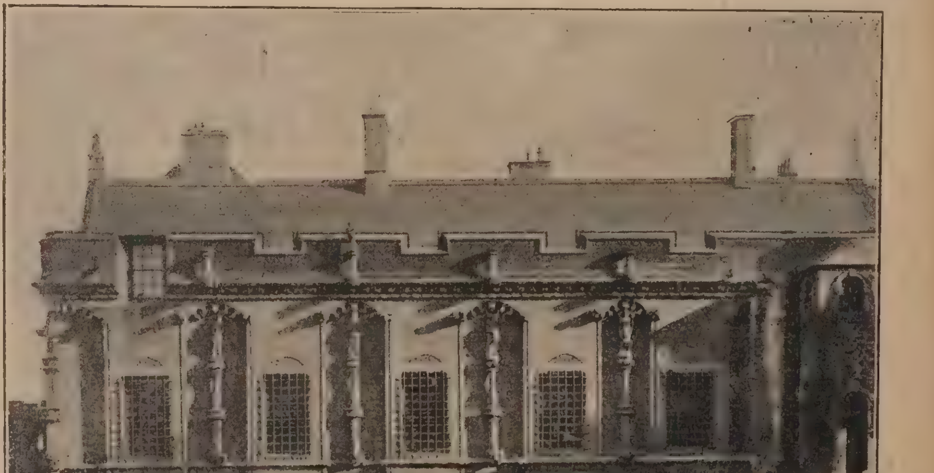
St. Columba's buildings were made of wattles and clay, and have long since disappeared, though the vallum or dyke which surrounded the monastery is still distinctly seen. But stone buildings of a later period, dating from about 1200 to 1400 A.D., still exist. The interest of the island centres round the Abbey, the Nunnery, and the Reilig Oran. The Nunnery, which was a Benedictine establishment, was founded in 1203 by Reginald, Lord of the Isles, whose sister was the first prioress. The Reilig Oran, or burial-ground of St. Oran, lies to the south-west of the Abbey, and contains more than forty tombs of Scottish, Irish and Norwegian kings and chiefs and church dignitaries. Both here and at the Nunnery are many slabs carved with beautiful Celtic patterns, showing a great amount of artistic feeling. These are an endless source of research and curiosity to the antiquarian, and might suggest some useful schemes of ornament to the designer.

St. Oran's chapel, called after one of St. Columba's followers, lies to the north-east of the burying-ground. It is supposed to have been erected in 1074 by Queen Margaret. It has a pleasing little doorway of Norman character at the west end.

The Abbey itself is full of interest, both to the antiquarian and the architectural student. There are at least four different periods of building, the earliest dating from about 1200, when Reginald, King of Argyll, rebuilt the monastery; but most of the church is late Decorated work, about 1400. The whole building is a patchwork of different periods, and as the same materials have been used throughout it is difficult to ascertain the exact dates.

The monastery has consisted of a church, with nave, transepts, choir, and south aisle, the cloisters lying to the north, while round them are grouped the chapter-house, library, parlour and dormitories, lavatory and refectory. We will go round these buildings and examine their various points of interest.

The first object that attracts our attention on approaching the Abbey is the famous St. Martin's Cross. It is covered with raised circles, and serpents twining amongst them. The origin of the circle enclosing the arms of the cross is supposed to be the remnant of the **P** loop in the well-known symbol, but this is doubtful. There are the remains of two other crosses, and a well near the west doorway, and also the supposed site of the shrine of St. Columba and his servant Diarmid. A curious hollowed stone lies near the west doorway, looking like a drinking-trough. This is called the Cradle of the North Wind, some persons on the island having the power to raise a storm by muttering an incantation over it—rather a dangerous faculty on that rocky coast. A curious little room, evidently used as a porter's lodge, overlooks the west doorway. This has been the principal entrance to the church, and is of late design, with three orders of shallow mouldings carried round jamb and arch. The base stops in a curious manner without any return, and is again completely stopped on the south side of the nave, where it joins the earlier west wall of the south transept. The nave walls are broken down, and only the lower portions of two windows in the south wall remain. The view from the south side is one of the best; all the work seen on this side is Decorated. The south aisle is spanned by two curious arches or flying buttresses, which have been built afterwards as an additional security to the piers. They come in very awkwardly with the clerestory windows, which are very small. The caps of the south aisle piers are the most interesting details in the building. They are covered with figure subjects, some of which have a strong Romanesque feeling; others are crude, but full of life and vigour. The subjects are the usual ones, Adam and Eve, an angel weighing souls, the Crucifixion, &c. There is a strong Renaissance feeling in this part of the church, which shows its late date. It is impossible, however, to fix any definite period, as we have no record of the building. Iona Abbey, being shut off more or less from the rest of Scotland, and being under native Celtic influence on the one hand and foreign Renaissance influence on the other, naturally differs



NORTH ELEVATION, STIRLING PALACE.

considerably from other buildings. There has been a side altar in the south aisle lighted by an eastern window, with a piscina opposite. This window has fully more stone than daylight in its tracery, but when worked out shows a peculiar and rather pleasing design, the wheel of the tracery being carried down into the body of the window. The south window of the presbytery is identical with the south transept window. The tracery is heavy and the mouldings shallow and late. The east window is of two periods, the jambs belonging to an earlier window, while the tracery has been filled in afterwards. The north window of the presbytery is the best design of the three. There are two consecration crosses on the east gable, two of five in the building. These are sinkings in the stone in the shape of a Greek cross with rounded ends, and were cut at the dedication of the church. The sacristy opens off the choir on the north, and contains two side windows, the upper one having the triangular pre-Norman head, but ornamented with the dog-tooth inside. This part is Transitional. Continuing our way round the building, we pass the outside of the chapter-house, and come to a small chapel, lying at a different orientation from the church. There is nothing remaining now but four walls and a fragment of the doorway. Passing the dormitories, of which very little remains, we come to the lavatory, through which the monks ingeniously turned the mill stream which flows hard by, and so had a well-flushed drain. All these buildings are much broken down so that it is only by comparison with other conventual establishments that the use of these various offices can be ascertained. The foundations of another building lie to the east: it may have been another dormitory or a hospital. Coming to the north side of the cloisters we have the exterior of the refectory with its straight buttresses and early pointed windows, the only one of the outbuildings with any pretence to design. The lower part has been used as a cellar, and the upper windows have lighted the dining-hall, which has been entered by a stair to the east.

We enter the cloister garth by what has been a fine Early English doorway belonging to the refectory, and used before the present cloister garth and the rooms to the east were built. This corner of the cloister has also had a small lodge over the entrance, as at the south corner. The cloister itself has been rather elaborate, covered with a lean-to roof resting on the main walls and supported by an arcade round the garth. This arcade is quite gone, but one or two bases and caps remain which show that it has rested on twin shafts and has been considerably ornamented with Celtic carving. The south-west corner arch still remains, and shows the valley gutter above.

Taking a general view of the cloisters, it will be seen that the chapter-house lies to the east, separated from the north transept by the slype or passage. Over the chapter-house was the library, which contained a large and valuable collection of books.

The chapter-house arcade is a curious example of Transition work, the arches retaining the Romanesque form, but being filled with dog-tooth ornament.

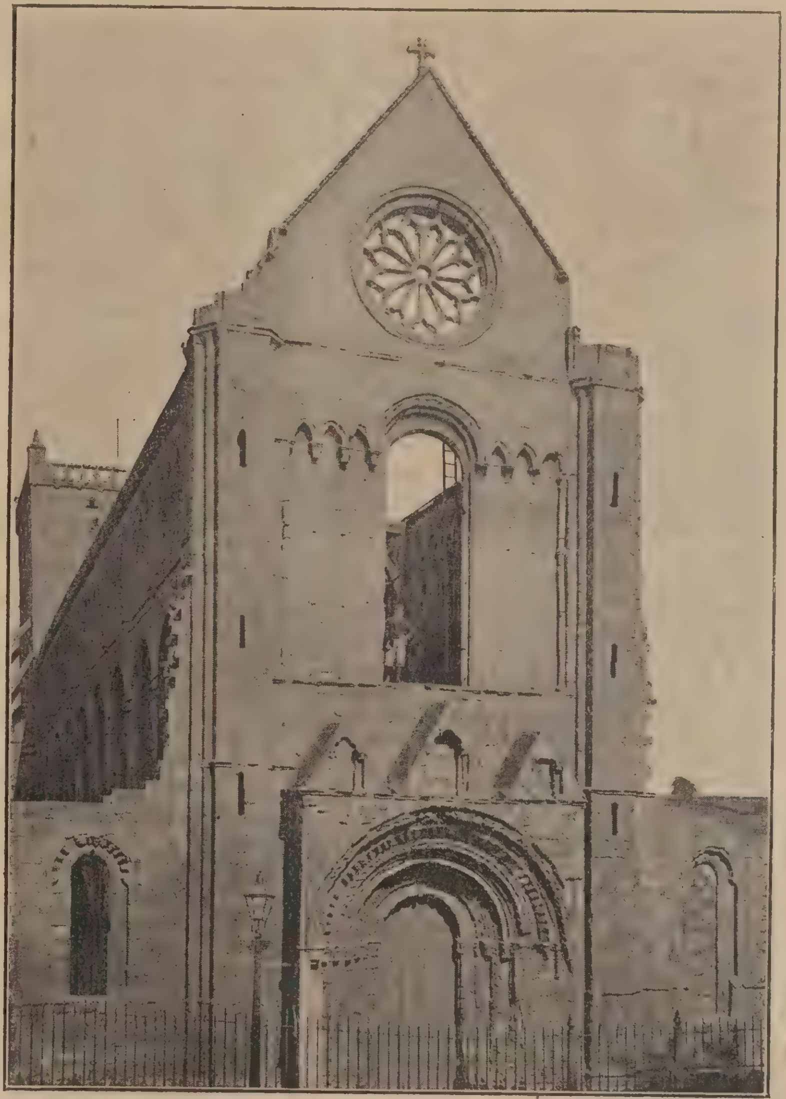
We enter the north transept by a door in the corner of the cloister. This is the oldest part of the building. The recesses and niche in the east wall, and the arch under the tower adjoining, all have caps and mouldings of late Norman style. There has been an altar between the two recesses, and a small window in the opposite wall has lit up a figure of the Virgin. The tower is supported by four arches over the crossing, and has been divided into four storeys. The belfry floor is pierced with large square traceried windows on three sides and on the north with a simple two-light window set in a square panel. It has been covered, according to old prints, with an ordinary saddle-back roof rising inside the parapet. The caps in the crossing are interesting, being carved with foliage and figures better executed than those in the south aisle. On the abacus of the cap of the south-east pier is an inscription:

DONALDVS O'BROLCHAN FECIT HOC
OPVS.

There was a Donaldus O'Bralchan who came from Ireland about 1203, but as the pier and cap moulds belong to the fourteenth century this affords little clue to the date.

The arcade opening to the south aisle has a sturdy and solid feeling which is helped by the somewhat short and thick cylindrical columns. On the south side of the presbytery is the sedilia, seated for the three officiating ministers, and close by, the piscina, much mutilated by tourists, but still bearing traces of a beautiful design. The Celtic carving in the spandrels of the sedilia is, or has been, good, but otherwise the design is inferior. In front of this lies the effigy of Abbot McKenzie, much worn away, and on the opposite side that of Abbot McKinnon, in better preservation, with a good inscription round his slab. On the north side of the choir is the doorway to the sacristy, one of the best pieces of design in the building. It is a late addition, however, as seen from the earlier character of the arcade above, which has formerly opened into a raised side-chapel. This has probably had a communication, by a passage in the thickness of the east wall of the north transept, with the library and so to the parlour and other buildings on the north, so that the monks could watch the ceremony without entering the choir. This arcade is of exactly the same character as that in the chapter-house, except that this is pointed, while the latter is round.

We have now in a general way gone over the building. Our travels were now near an end, and having purchased the inevitable green stones and white heather we sailed in the beginning of September for Oban, and escaping with difficulty from the attentions of fifty hotel porters, got to our train and arrived safely in Edinburgh once more.



JEDBURGH ABBEY: WEST FRONT.

Views and Reviews.

Planning.*

"Memorabilia" rather than "Principia" suggests itself to the reviewer as the true term to characterise the scope of this readable little volume dealing with a subject of vital importance to the architect. Mr. Marks shows himself to have been a diligent note-taker, a faithful keeper of the architect's commonplace book, while he has sufficient power in arrangement and lucidity in writing to be able to throw his multifarious facts into a coherent whole.

It has been naturally impossible for the writer of this work to be equally expert in every class of the buildings he classifies, and while he is evidently at home in some of his subjects, there are others in which the treatment is somewhat cursory, and others again where matters of importance have been passed over or even altogether omitted. This, however, is only a first edition, and considerable revision and extension may be expected when the author's labours have found a fitting recognition.

The eighty plans are far too few to adequately illustrate such a subject, and they have been selected in a somewhat uncertain manner; in some cases they are not sufficiently up-to-date, and in others very much better examples might have been given. In addition to any defects in the illustration from actual work, however, there is also a lack of illustrative

---

* "The Principles of Planning." By Percy L. Marks, B. T. Batsford, 94 High Holborn, W.C. Price 6s. nett.

STIRLING TOWN HALL.

diagrams which would save much of the letterpress of the book. For an architect, the author is curiously given to work out his calculations in written rather than in geometrical figures. For instance, in dealing with a suggested minimum size for a bedroom, he arrives, by a curious process of calculation, at 9ft. × 8ft., but had he drawn the proposed room, with the furniture in place, he would surely have discovered that 10ft. × 7ft. would give him a better result. It might have been noted in this connection that 12ft. × 8ft. is a standard hotel bedroom dimension.

We gave the scope of the book as "memorabilia" rather than "principia" because of the general laws of planning the author has little to tell us. His treatment of design in relation to plan best exemplifies this. "The word 'design,'" he informs us in a footnote, "throughout this book is used to signify the treatment of the elevations." Of beauty in planning, of the interest and suggestiveness of a good plan, apart from the convenience of its arrangement and the fulfilment of all the utilitarian requirements of the case, he would appear to have little or no conception; while stranger still is the omission of any hint of the importance of the element of evolution in plan, of the gradual growth of type, and of the importance to the student of the recognition and study of these factors in historic planning, as affording to them a clue to the tendencies of the work of their own time.

It is the failure to grasp this side of the question that probably accounts for the author supposing that for church planning one example, and that a mere revival church like St. Mary Abbots, Kensington, would be sufficient illustration. The requirements of modern church planning have been very inefficiently understood, as may be gathered when it is pointed out that there is no mention of the supreme importance, in town churches, of communicants being able to pass through, and to return from, the chancel to their seats with the decency and order requisite to the service.

In a similar way club planning hardly began and ended with the Constitutional Club in Northumberland Avenue, while the essential difference between a modern club of that type, with its hotel-like characteristics, and the domestic-palatial order of the older clubs (such as, for instance, the Reform Club) is nowhere alluded to.

The value, therefore, of Mr. Marks' work appears to us to be that it brings together in a handy work a collection of those facts and figures which are the indispensable basis of a plan. It is strange how difficult it would be to say off-hand where to find, for example, the number of cubic feet required to house a ton of coal, or where to lay your hand on the exact data of the spacing of a school dining-room, or where to hit upon a complete list of the requirements of, say, an abattoir. Such facts have doubtless been given many times before, but in their scattered state they are comparatively useless. It takes too long to hunt them up, when the need arises, in many books. Further, if the possession of this work brings home to the student and to the young architect the value of such memoranda and leads them to use their eyes, rule, and notebook to greater advantage, it is clear that the author's aim will have been accomplished.

The work is divided into ten chapters, with two appendices. These latter are extracts from the L.C.C. by-laws as to theatres and from the Education Code for school buildings, both of which would be better given in full, as extracts in such matters are of doubtful assistance, if not actually dangerous.

Chapters I. and II. of "Introductory Remarks" and the "Enunciation of Broad Principles" may be passed over to arrive at Chapter III., "Essential Features, Accommodation, &c.," which is the core of the book. It is an alphabetically-grouped list of buildings from abattoir to workhouse, giving under each head (*a*) essential features, and (*b*) requisite accommodation in each case, followed by a few explanatory notes.

Some of the classes are well treated, evidently those with which the author has had some personal acquaintance. Synagogues, for instance, are well explained, though a plan of one might well have been given. Take, however, as an instance of the author's method, *Art Galleries*: "(*a*) ample accommodation for works of art and for the public, top light in galleries, symmetrical treatment (under the best conditions), good staircases; (*b*) galleries for various classified works of art, packing and delivery rooms, and clerical offices, cloak and umbrella stores, lavatory, &c., refreshment room, picture hoist, stores, caretaker's rooms, &c."

The above, with a plan of the Royal Academy galleries, can hardly be described as adequate. For instance, under (*a*) nothing is said as to the circulation of the public, *i.e.*, the arrangement of the galleries so that no room can be traversed twice, or made into a cul-de-sac. Nor in regard to lighting is there any reference to the value of side-lit rooms for cabinet works, nor any note as to the importance of avoiding features such as domes and towers that would cast shadows over the skylights. Again, the proper width for a gallery is a point of the greatest importance on which the author is silent, while there is no diagram of a scientific gallery section that will avoid reflections on the pictures.

Under (*b*), again, a student might miss the curator's room (used also for committees), which is apparently comprised in the term "clerical offices."

A curious omission in the book is that of restaurants, the data for which might most usefully be given. In all cases there ought to be a reference to sources of detailed information, and a short list of good typical buildings.

Expanded on these lines in a second edition the book would be of great value to students and a handy *aide-mémoire* to architects.

The remaining chapters of the book may be briefly indicated. Chapter IV. deals with "Aspect." The buildings are here also alphabetically listed, but in too brief a form. Schools, for instance, are left out, whereas the fact that the London School Board prefer east and west for their normal type of plan might well have been stated.

Chapter V. deals with "Privacy and Seclusion," door-hanging and the position of the W.C. in house-planning being dealt with in detail.

In Chapter VI., under "Roominess, Furniture Requirement, and Prospect," circularity in preference to angularity of furniture is advocated for small rooms.

Chapter VII. is concerned with "Grouping," the service from kitchen to dining-room, and the passage from the drawing-room, and that between bedrooms and bath-rooms, are all referred to.

"Staircases and Miscellaneous Features" fill up Chapter VIII., with remarks on cupboards, inglenooks, porches (but with the omission of porte-cochères) and fittings. In Chapter IX., "Economy," there is a good diagram of the old Board School staircase, two in one cage, the use of two colours making the construction quite plain. The last chapter, No. 10, "Design in Relation to Plan," contains little more than some comments on symmetrical disposition and on the abuses that arise from a false use of the same.

The odd humour of the author relieves the monotony of the subject with an occasional riddle; how, for instance, he extricated his lady client from an extra special bijou staircase that she had rashly ascended, the use of the hatchet being expressly barred, is left as the judicious mystery of page 83. X. Y. Z.

Improvements at Yarmouth.—A Local Government Board enquiry was held recently into an application for a loan of £7,500 for improvements at Gorleston. It is intended to continue the existing cliff improvement by the addition of a strip of cliff 2,394ft. long, the top of which would be laid out with grass, for use as a public promenade, while at the foot a concrete retaining wall would be built, which would contribute to shore protection.

SURREY ARCHÆOLOGICAL SOCIETY.

The Plan of a Cistercian Abbey.

THE annual report of the council of the above society states that though the increase in membership during the past two or three years has been considerable the council is persuaded that the number does not yet adequately represent those who are interested in the archæology of the county. Much interest naturally attaches to the excavations at the ancient Cistercian abbey at Waverley, near Farnham. The council states that these were continued last summer under the superintendence of the Rev. T. S. Cooper and Mr. Henry Horncastle, with even more important and satisfactory results than hitherto. The work has been at times very perplexing, owing to the many and unexpected walls and footings found of the Norman abbey, mixed up with, and sometimes made use of in, the later buildings. In the previous year Mr. Brakspear discovered the little presbytery of the Norman church in, and forming part of, the south transept of the later magnificent church planned by William de Bradewater. The long narrow Norman nave has now been traced below the cloister. The original cloister was at some time considerably enlarged and carried across the cellarium as well as the nave of the first church. The arrangement of the frater and its pulpit is interesting, as it shows the former to be of two dates at least. The plan of the infirmary hall and kitchen is now clear, and it has become evident that there was no building between this portion of the Abbey and the river. Some interesting features, too, have come to light in the direction of the monks' dormitory. Much of the Norman work here remains, with the south wall on a line with that of the frater; later the dormitory was extended southwards at a higher level almost to the river bank. At the north end the doorway leading from the cloister and the fine broad steps ascending to the dormitory have been exposed, and, close by, a winding staircase which probably formed the approach to the treasury. The plan of Bradewater's church also is now nearly complete. There is still a good deal to be done west of the cellarium, where the guest houses, the infirmary of the conversi, and possibly a gateway may be looked for. This is of almost greater importance than the work already done, since these buildings of the outer court have never been worked out properly anywhere; both at Fountains and Furness the remains of them are anything but complete, and at the former it is known there were a number of buildings of which no trace can be found. The Society has therefore the opportunity of adding materially to what is already known of the plan of a Cistercian abbey, an opportunity which may not present itself again.

THE ACOUSTICS OF CHURCHES AND PUBLIC BUILDINGS.

By Charles E. Savery.

THE word "acoustics" raises the most disquieting thoughts in the minds of architects, who have before them a long array of admitted failures in this important matter. Many buildings erected from the plans of some of our ablest men are defective, such as St. Paul's Cathedral and several of the churches built by the leading architects connected with the Gothic Revival.

It seems that the acoustic properties of a building can only be judged after its completion, and that no rule therefore exists by which any certainty of result can be depended on. Our attention may be best directed to an attempt to remedy, or at least improve, the acoustic properties of building where the defect complained of exists. We are very apt to attach blame to construction when the fault really lies in the arrangement of the rostrum or pulpit, in the case of a preacher or speaker, or in the position of the organ or choir stalls in regard to musical sounds.

At the outset the very arrangement which tradition has almost made sacred presents an obstacle to good acoustic results. Take the case of a church. We have first the aisle, then probably two side aisles with various openings extending to a chancel, with possibly a chapel attached. Add to this two or more transepts and you at once have a building with half-a-dozen different outlets for a preacher to adequately fill.

He is expected also to make his voice reach each part of the building from a spot neither in the middle nor at the end of the building, the favourite position being at an angle of one of the transepts, where the voice waves are broken up into minute particles, growing naturally feebler the more that they are diversified. Of course when great height is sought, as in St. Paul's Cathedral, a considerable echo is the result; and this in a modified degree is not altogether objectionable, especially in the case of musical sounds, the rolling notes of the organ alternately rising and falling with imposing effect. But the same cause operates *against* the preacher's voice being perfectly heard. So far, therefore, as preaching is concerned, the position of the speaker is of great importance. Our forefathers showed that they recognised this when they placed the pulpit in the middle of the aisle and they further exhibited their common-sense by placing a sounding-board at the back of the pulpit. The strain to which the voice is subjected whilst preaching for, say, only half-an-hour can be appreciated only by those who have experienced it, and they alone know the aid which these old-fashioned boards afford. The principle of such help is at once apparent in the construction of many of our musical instruments.

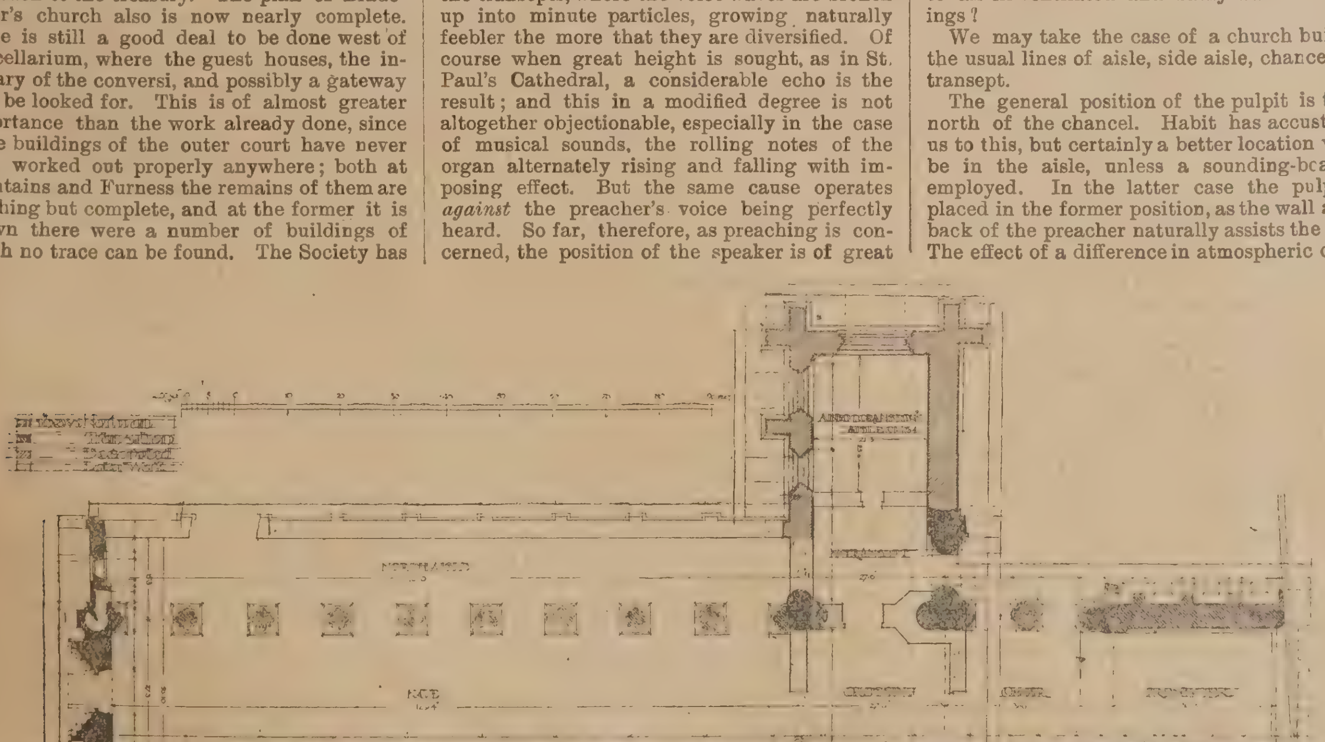
Where the traditional planning of ecclesiastical buildings is not followed, it certainly allows the architect a greater scope for studying the natural laws of acoustics, instead of having to adapt them to a particular type of building. I say "adapt" them, yet in the majority of instances there is so much uncertainty in the result that it is quite a matter of speculation as to whether after the fabric is finished it will possess entirely satisfactory properties.

Some buildings with which great care in planning has been taken with a view to good acoustics have an unpleasant vibration, rendering a preacher inaudable at a short distance away. In such a case wires stretched across the building have proved very helpful. These assist the natural vibrations of the voice, as opposed to those caused by mere echo. Persons accustomed to either sing or speak in public, more especially the former, know by experience when their voice fills the auditorium. There is nothing more trying than to find a difficulty in doing this. The voice seems as if it had no resonance, and great exhaustion is very frequently the result of prolonged efforts under such conditions. It therefore becomes necessary to break up the opposing echoes before satisfactory results can be obtained, and at the same time to arrange that there shall be no confusion of sounds which it is desired should be actually heard.

The atmosphere in a large building also considerably affects the waves of sound. On a damp foggy day noises close at hand often sound indistinct; and may not the same apply to all ill-ventilated and badly-warmed buildings?

We may take the case of a church built on the usual lines of aisle, side aisle, chancel and transept.

The general position of the pulpit is to the north of the chancel. Habit has accustomed us to this, but certainly a better location would be in the aisle, unless a sounding-board is employed. In the latter case the pulpit is placed in the former position, as the wall at the back of the preacher naturally assists the voe.ic The effect of a difference in atmospheric condi-



PLAN OF JEDBURGH ABBEY

tions would probably be felt more in a very large building capable of seating, say, a couple of thousand persons than in a smaller edifice, for the simple reason that where a quantity of heavy atmosphere accumulates it increases the difficulty of sound penetrating it. For example, in a small building on a foggy day the inside warmth will generally tend to disperse the fog, but in a very large building the atmosphere will frequently remain in a clouded state, despite all efforts to remove it.

Wires will frequently obviate echo: they need not be unsightly or placed too low. With regard to vocal and instrumental sounds in churches, the choir is generally placed, in accordance with custom, in that part of the building bearing this name, and, as a rule, the choir stalls face each other. Now it is obvious that in a very small chancel the voices cannot be heard to the best advantage from the body of the church. Here, again, tradition has made this arrangement almost a part of the economy of seating. Where, then, should the choir be placed? Some authorities have advocated a position in a raised gallery, and in many of our old churches prior to the Gothic Revival the favourite position for choir and organ was in the western gallery. Singing galleries were undoubtedly in common use in the middle centuries, both in England and on the Continent.

It must be borne in mind that where all is subservient to the exigencies of the particular form of church worship for which a building is designed the question of sound must be a secondary consideration. It is rather, therefore, to the solution of such obstacles as present themselves in connection with these arrangements that we should direct our attention. We have already spoken of the different aids to speaking which may be usefully employed, and in a modified degree the same applies to vocal music: identical difficulties have to be encountered and similar remedies applied to counteract them. The position of the singers themselves is a question not, perhaps, sufficiently appreciated. It stands, however, to reason that anyone with his head inclined towards a low desk or stall cannot properly direct his voice so that it shall be heard distinctly: the sound is thrown down and depressed instead of being transmitted towards the congregation.

Opinions differ widely as to the best position for the organ. The customary place assigned is near the choir. In the end of the eighteenth and till the middle of the last century the organ was located in the west gallery, and on purely acoustic grounds this is frequently the best position: the objection is that the choir is then too far from the organ. But a means of removing any such difficulty may be found in employing a console connected by electricity with the instrument. This, however, with an old instrument would mean possibly a remodelling of the original organ, and probably at considerable cost. We have therefore to consider how best to deal with the existing arrangement and at as little expense as possible.

Let us say that an organ chamber, so called, is *not* the best place for an organ. Who would think of putting a piano in a cupboard and expect to get satisfactory results from it? It is just as unreasonable to place the more powerful instrument in an organ chamber, *i.e.*, in its general form. The very elementary principle of sound affecting the construction of organ pipes is apparently entirely lost sight of here, for, independently of the impossibility of such being clearly heard, the pipes themselves require a certain amount of space to allow them to speak freely. Take, for the sake of example, the large 32ft. organ pipes. These are frequently built up *close to the roof*; and as a result we have a heavy booming noise like rolling thunder, instead of distinctness of voicing; we have chaos of sound, alike trying to choir and congregation. There is also a considerable waste of force in placing an instrument in such a situation. A far less powerful organ properly placed would sound better if given the chance of being adequately heard. Organ pipes should be at an adequate distance from the surrounding walls or roofs so as to be properly heard.

Another important point concerns the proper elevation of the instrument from the ground. This would depend of course upon the construction of the building. But provided that sufficient space is given above the instrument, this elevated position would undoubtedly improve its sound. In some of our cathedrals the organ has been placed above the screen dividing the choir from the body of the church. Such a position, I venture to think, is entirely wrong. It quite destroys the perspective of the interior, apart from other considerations. In many cathedrals two organs are frequently now used, both worked from one console. The effect is of course very beautiful, but we are now concerned with acoustics. Another position the organ should *not* occupy, though frequently assigned to it, is that immediately over the heating chamber. Here the wooden pipes become dry and brittle, giving imperfect tone, besides adding to the risks incurred through any outbreak of fire.

The foregoing suggestions on such an important subject are merely superficial. The details will be easily supplied by those readers conversant with the difficulties which the matter presents. But though these cannot be wholly removed, existing arrangements could frequently be improved so as to add alike to the comfort of preacher, singer musician, and, most important of all, the congregation itself.

PLYMOUTH WATER-SUPPLY.

THE BURRATOR WORKS.

AT the meeting held on April 2nd of the Institution of Civil Engineers a paper on "The Burrator Works for the Water-Supply of Plymouth" was read by Edward Sandeman, M.Inst.C.E.

The waterworks of Plymouth dated from 1590, in which year Sir Francis Drake, under powers conferred by an Act of Parliament of 1585, had commenced to build a weir on the River Mewe or Meavy, and to excavate an open watercourse or leat from the weir to Plymouth, a distance of 10½ miles in a direct line, but 18¾ miles along the route taken. The drainage area above the weir was 4,885 acres.

The work had been completed, and water had been brought into the town in April, 1591. Water taken from the river by this means had supplied the town for 300 years. The open watercourse, however, was liable to be blocked in times of snow and frost, and for this reason, and also because the increased population demanded a larger and more certain supply, various schemes had been promulgated for the storage of flood waters and the protection of the leat. In 1891 Mr. Sandeman had been appointed water engineer, and a few months later he presented a report, which had been adopted, advocating the building of a storage reservoir and the substitution of a line of pipes for the open leat. An Act of Parliament had been obtained in 1893 for the construction of the necessary works, which had been commenced in August of that year, Mr. James Mansergh, President Inst.C E., acting as consulting engineer.

By the new scheme the drainage area had been increased from 4,885 acres to 5,360 acres. Nearly the whole watershed lay on the granite formation, a small portion on the west side being on the Upper Devonian. The rainfall was about 58in. or 60in. annually, and an interesting feature of this gathering-ground was the unusually high dry-weather flow from it.

The Burrator reservoir was formed by two dams, one of masonry across the narrow gorge through which the river Meavy flowed, the other of earthwork lying between two hills, Sheepstor and Burrator. The greatest depth of water was 77ft., and the area covered by water was 117 acres, the quantity of water impounded being 657,000,000 gallons.

The masonry dam (called the Burrator dam) was built of large rough blocks of granite in cement in the interior, and faced with irregularly coursed granite on both sides. From bottom of foundation to coping of parapet wall, the height was 145ft. 6in. A roadway, 18ft. wide, was carried over this dam on five segmental arches of 25ft. span.

The earthen dam was remarkable for the fact that its construction had involved the cutting of a very deep trench for the foundations, although the dam had to withstand but a small head of water. The trench had been cut through decomposed granite to a depth of 105ft. in the centre, although the depth of water against the dam was only 17ft. This trench was interesting on account of the peculiar geological features met with. The water-tight core of the dam was of concrete (5ft. thick) up to within a few feet of ground-level, and of clay from that point upwards.

Water was drawn from the reservoir through two pipes of 36in. and 25in. diameter respectively, laid in a 10ft. culvert built in the masonry dam. There was no valve-tower. There was a specially designed valve to close the mouth of each outlet pipe, worked by gun-metal rods and chains from a chamber at the top of the dam, in addition to sluice valves in duplicate in a valve chamber on the lower side of the dam. The water drawn for consumption was passed through screen-chambers before entering the pipe leading to the service reservoirs. The flood water running to waste was measured over a weir 50ft. wide, the height of the water over the weir being recorded on a drum turned by clockwork. The compensation water was measured by an orifice gauge placed immediately below the weir. The water supplied to the town was measured over a gauge-weir 12ft. wide, after which it passed through a 25in. Venturi meter, which automatically recorded the flow on a diagram.

The pipe-line, which had been laid in lieu of the old leat, was 4½ miles long. The pipes were of 25in. diameter, and were capable of delivering between 8,000,000 and 11,000,000 gallons per day. The pipe-line had been completed in May, 1894, and the reservoir and other works in June, 1899, at a total cost of £178,000.

STONEHENGE.

RECOMMENDATIONS FOR ITS PRESERVATION.

THE recent fall of stones at Stonehenge having led to much public discussion, Sir Edmund Antrobus, of Amesbury Abbey, Wilts, invited the Society of Antiquaries, the Wilts Archæological Society, and the Society for the Protection of Ancient Buildings to advise him with regard to the better preservation of the famous monument.

A committee representing these three bodies met on March 26th, under the presidency of Viscount Dillon, the president of the Society of Antiquaries, at which meeting the following resolutions were passed:—

1. That this committee approves of the suggested protection of Stonehenge by a wire fence not less than 4ft. high following by two sides the existing roads and crossing on the west from the 331ft. level on the north road to the 332ft. level on the south road shown on the O.S. map (1-2,500), Wilts, sheet liv., 14.

2. That the committee recommends, without prejudice to any legal question, that the local authorities be requested to agree to divert the existing trackway or ridgeway from Netheravon now passing through the earth circle so as to pass from the 302-ft. level to the 331-ft. and 332-ft. levels in the O.S. map immediately west of Stonehenge.

3. That stones 6 and 7, with their lintel, and stone 56 (according to the numbering of Mr. Petrie's plan), be first examined with a view to maintaining them in a position of safety.

4. That, in the opinion of this committee, stone 22 should be replaced, stone 21 be made safe, and the lintel of 21 and 22 be replaced in the most safe and conservative manner. The committee also recommends the re-erection of stones 57 and 58, and their lintel 158.

5. That the instructions to custodians already in force be approved with a few suggested alterations.

6. That this committee feels that it is impossible to overstate the value of the assistance which the County Council, the District Council, and the Parish Council of Amesbury can give to the efforts made to preserve this unique monument.

7. That these resolutions be sent to Sir Edmund Antrobus with the earnest thanks of the committee for the part he is proposing to take in the preservation of Stonehenge.

DUNOON GRAMMAR SCHOOL.

IN November 1898 instructions were issued for competitive plans for additions to the Grammar School, and at a meeting of the board in January 1899, Mr. Fraser's plan was adopted. Operations were commenced in the month of July 1899. The central portion was commenced first, and when completed the north wing was started, the whole being ready for occupation by the end of 1900. The school, before alterations, consisted of a one-storey building, with the Secondary Department in two storeys, and contained 10 class-rooms. As now completed it contains class-rooms, with art-room, lecture-room, chemical laboratory, physical laboratory, cookery-room, music-room, with separate private rooms for the rector and lady teachers, separate cloak-rooms for the boys and girls and infant boys and girls, with separate staircases and entrances for each. Accommodation is now provided for 820 scholars, exclusive of the science and art rooms. The main entrance is in the centre of the building, with separate entrances for the boys, girls, and infants. The central entrance leads into the entrance hall, in which are the boys' and girls' staircases. The floor of the hall is laid with granolithic and mosaic, and the walls have a tiled dado 4ft. high. From the hall, corridors lead off on either hand on both floors, giving access to all rooms in the building. These corridors have also a tiled dado and granolithic floors. Immediately adjoining the entrances are the cloak-rooms, which have two doors, the students entering the school through them. The class-rooms are fitted up with a staging and dual desks of the latest pattern. The cookery-room is fitted up with a cooking-stove, sink, and cooking tables. The chemical laboratory is fitted up with chemical tables for 18 students, and the physical laboratory is fitted with tables for 18 students and a dark room, &c. The art room is arranged with staging on the semi-circular plan, and supplied with a complete set of models and casts, the windows having dark blinds, so that the light can be regulated as required. The whole building is heated by hot-water pipes from a central heating-chamber, and ventilated with automatic ventilators and fresh-air inlets. The colouring of the walls has been arranged so as to give a variety of colour schemes. The exterior architecture of the building has been limited by the style of the past, and by the fact that the old material has been used to a considerable extent. The contractors were:—Mr. Jas. Tannock, builder Mr. James Drummond, joiner; Mr. Hugh Stewart, plumber; Mr. George Macpherson, slater; Mr. Andrew M'Farlane, plasterer and tile-worker; Mr. Thomas Sweet, painter; Messrs. James Boyd and Son, Paisley, heating engineers; Mr. Young, joiner for the laboratory fittings; the Bennett Furnishing Co., for the seats and furniture; and Mr. William Shepherd for the tar macadam. Mr. Thomas Young, jun., acted as clerk of works, Mr. John Baxter as measurer. Mr. William Fraser is the architect. The illustration on this page was kindly lent to us by the "Dunoon Herald."

INVERURIE ABATTOIR.

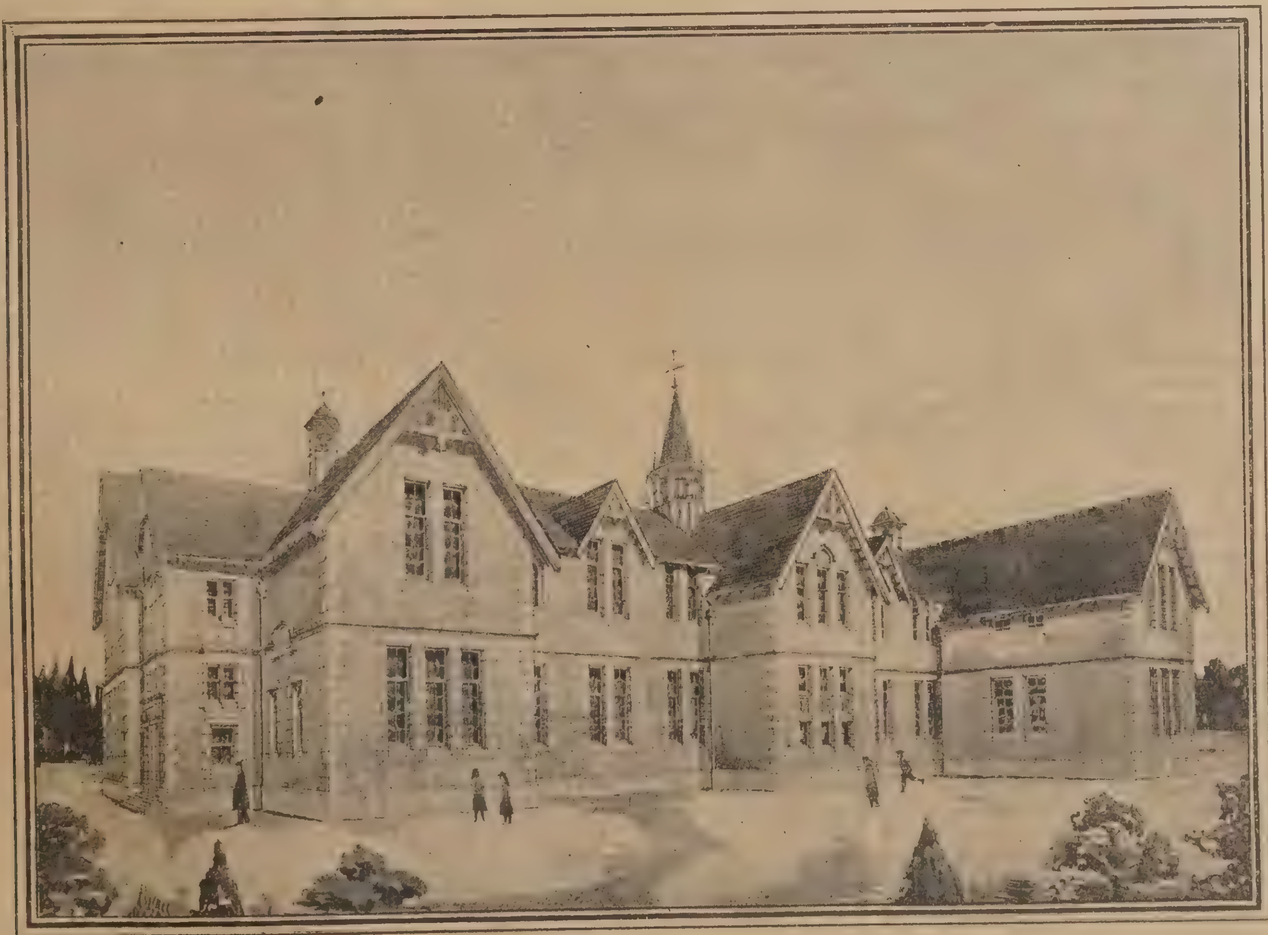
A MUNICIPAL slaughterhouse is being erected in North Street, near the market stance, and about 100 yards back from the line of the road. It consists of two buildings running parallel to each other. One of these is divided crosswise into six compartments, for killing and dressing purposes, by heavy iron railings. Large sliding doors provide for loading the meat on to lorries, and as each of the booths is entirely separated from the others a complete set of appliances has been erected in every compartment. Overhead rails have been fitted up for hanging the carcases, and there is a plentiful supply of fresh water. In order that everything can easily be kept clean and fresh, the floors are of cement and the walls have a covering of this material up to a height of about 6ft. The other building is divided off into byres, and communication is secured between these and the shambles by doorways in a mutual wall. Special provision is made for the killing of pigs, and in connection with this there is an installation of hot water. The slaughterhouse contains accommodation for six tenants, each of whom has a byre and a booth to himself. A roadway leading from the street divides into two and encircles the building, giving facility for handling the cattle and meat. The total estimated cost of the undertaking is between £2,200 and £2,300. The architect is Mr. George Gray, of Inverurie.

LEAD PIPES.

IN the course of a recent lecture before the Society of Engineers on "The Production of Metallic Bars and Tubes under Pressure," Mr. Percy F. Nursey, past-president, described the various processes and apparatus employed in the manufacture of bars and tubes by forcing metal through dies.

The primary application of this principle, he observed, was to the manufacture of lead pipes; but before describing the methods of their production he referred to some water-pipes made by the Romans which he inspected at Bath some years ago during some excavations in the Roman baths there. They measured about 18in. wide by 4in. deep, and were made from a dished strip of lead which constituted the top, whilst a flat strip, having its edges turned up over the edges of the upper strip, formed the bottom. The lead of which these pipes were made was stated to have been obtained from mines in the Mendip Hills, where lead pigs have been discovered bearing the stamps of the Roman Emperors Claudius, Vespasian and Hadrian respectively.

The author then referred to the early manufacture of lead pipes, which were made by either drawing or rolling cylinders of lead down to the required diameter on a mandrel which formed the bore. Lead pipes were also made by bending sheet-lead over a mandrel and soldering the edges. These unsatisfactory methods were in time superseded by the lead-pipe press, in which molten lead is placed in a heated container, and when cooled down to plasticity is forced through a die by hydraulic pressure. By this means, instead of only short lengths of pipe being made, as with the old methods, pipes of any required length are pro



DUNOON GRAMMAR SCHOOL. WILLIAM FRASER, ARCHITECT.

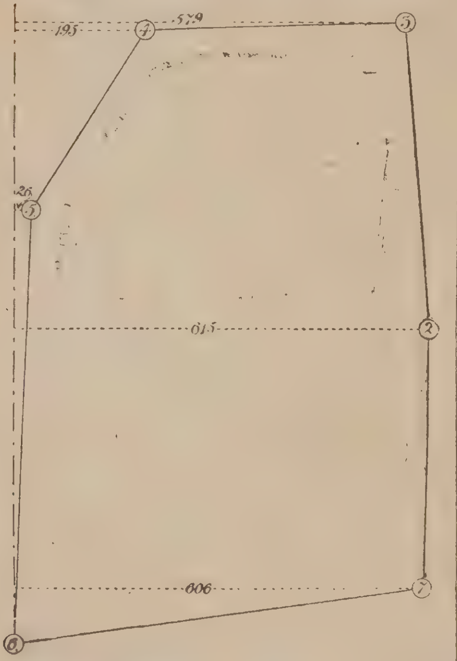
duced. The author described the process of manufacture as he had witnessed it at the Farringdon Works of Messrs. Pontifex, in Shoe Lane, London. He then described the improved lead-pipe press of Mr. Alexander Wylie, as made by Messrs. Wilson and Sons, of Johnstone, Glasgow, which is a considerable advance upon the ordinary lead-pipe press. In the later examples, instead of the container being kept hot by a fire or a ring of gas jets it is jacketed and steam-heated.

COMPUTING LAND AREAS.

By G. A. T. MIDDLETON, A.R.I.B.A.

[*All Rights Reserved.*]

AFTER a piece of land has been surveyed and the survey accurately plotted, it is a matter of no great difficulty to ascertain its area. The uninitiated, however, may do well to note that a plan is a horizontal projection, and that consequently the area as calculated should be the *flat* area, and not the *slope* area, in the case of hilly ground; and is in fact the true area.



COMPUTING AREAS BY EASTERLY OFFSETS.

The most usual system of computation is to divide the land into a series of triangles, neglecting irregular boundaries for the moment; and it is neither necessary nor usually convenient that these triangles should be the same as those used in the field work, even when the land has been surveyed on a system of triangles. The area of each triangle is ascertained by multiplying its base by half its altitude, these areas are summed, and the thing is done, except for the correction necessary for irregular boundaries. Often, however, where accuracy is not required, the boundary lines of the various triangles are so laid down as to form rough "give and take" lines, so compensating for irregularities; and if the dimensions be in links the whole process is then one of extreme simplicity. But it lacks accuracy. The bases of the triangles and their altitudes have to be measured by scale, and a very small error in either may make a really serious error in area possible.

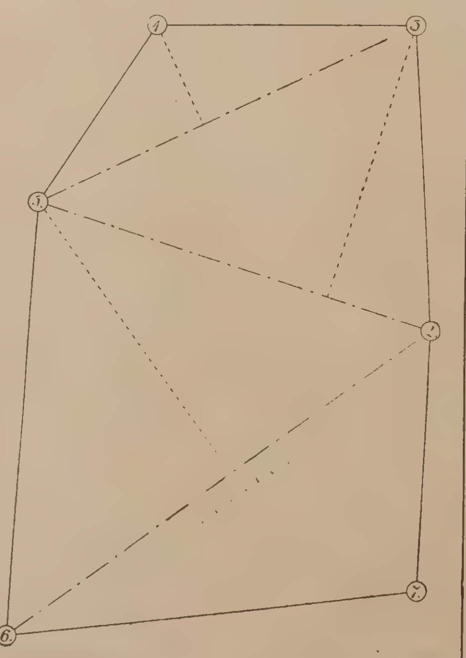
Another and much more accurate system of computation is that by means of easterly offsets from a meridian line drawn through the most westerly station of the survey; and where the survey has been by theodolite traverse round the boundary lines it may be considered to be absolutely accurate, as the easterly offsets can be accurately obtained from the Traverse Field Book, as can also the northerly and southerly distance travellings of the separate boundary lines. According to this system, the offsets of each pair of stations in succession from the datum meridian are summed, and multiplied by half the Northing or Southing. Areas made up by Northings are summed—so are those made up by Southings. The Southing areas are deducted from the Northing areas, and the result is the area of the land.

Thus in the plot chosen for illustration, the meridian passes through Station 6, which consequently has an offset of 0, while the offsets from the meridian of Stations 7, 2, 3, 4 and 5 are 606, 615, 579, 195, and 26 links respectively. Further than this, from 6 to 7, there is a Northing of 84 links, from 7 to 2 a Northing of 386 links, from 2 to 3 a Northing of 450 links, from 3 to 4 a Southing of 11 links, from 4 to 5 a Southing of 267 links, and from 5 to 6 a Southing of 642 links. Put into tabular from the whole works as follows:—

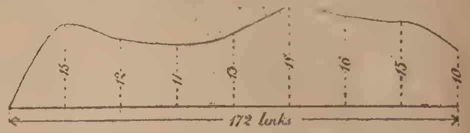
Station	Easterly offset	Sum of Easterly offsets	Half Latitude	Northing areas	Southing areas
6 7	0 606	606	42 N.	25,452	—
7 2	606 615	1,221	193 N.	235,653	—
2 3	615 579	1,194	225 N.	268,650	—
3 4	579 195	774	5·5 S.	—	4,257
4 5	195 26	221	133·5 S.	—	29,503
5 6	26 0	26	321 S.	—	8,346
			Totals Subtract	529,755 42,106	42,106
			Area	487,649	

This area is in square links, and as there are 100,000 square links in an acre, and it is a decimal measure, it is at once seen that the area is 4·87649 acres. Multiplication of the decimal 0·87649 by 4 reveals that this is 3 50596 roods, and multiplication of 0·50596 by 40 brings it to 20·2384 poles, the result, according to the usual notation, being 4 acres, 3 roods, 20¼ poles nearly.

This would probably have to be rectified by some small corrections for irregularities of outline as measured by offsets from the boundary lines. No method of computing curved outlines can be considered as absolutely correct, but that most usually adopted may be stated as follows:—The length of the base line (or boundary line) is divided into equal parts, any convenient number being taken (it being remembered that the greater the number the closer the approximation to accuracy) and offsets being measured at each of these points The offsets at the two extreme ends of the base are summed, and added to twice the sum of all the other offsets, the total thus obtained being multiplied by half the base line and divided by the number of divisions (not offsets) taken.



COMPUTING AREAS BY TRIANGULATION.



COMPUTING AREAS OF IRREGULAR OUTLINE.

Thus in the example taken for illustration, the offsets at the extremes are 0 and 10, and the intermediates are 15, 12, 11, 13, 18, 16, and 15, while the length of the base line is 172 links, and the number of divisions is 8. The area, then, is

$$\left\{0+10+2(15+12+11+13+18+16)\right\}\times\frac{172}{2}\div 8$$
$$=(10+170)\times 86\div 8$$
$$=180\times 86+8$$
$$=\frac{15480}{8}$$
$$=1935 \text{ square links.}$$

NORMAN CHURCHES IN THE EAST RIDING WOLDS.

AT a recent meeting of the East Riding Antiquarian Society the chairman (the Rev. E. Maule Cole, F.G.S.) read a paper on "Norman Work in Old Churches." He said that in the chalk wolds of the East Riding was a greater wealth of old Norman churches than was perhaps to be found anywhere else in a limited area. The fonts, as a rule, were remarkably well preserved, and some of them dated back even to Saxon times. That at Cottam represented the martyrdom of St. Lawrence. The old font at Cowlam was a beautiful specimen, and was said to be Saxon. Great Driffield church was commonly said to have a Norman arcade, but that was, strictly speaking, not correct. It was Transitional. At Little Driffield the only Norman remains consisted of an early plain tower arch with a square abacus. At Fridaythorpe the church had almost fallen into decay and was about to be restored. There was a fine Norman chancel arch, and the south doorway showed somewhat late Norman chevron work in the arch.

Proceeding with the thirteen churches in his list, the lecturer said that the present Norman church at Garton was probably preceded by a Saxon one. The tower was extremely massive, and as wide as the nave. There was a Norman doorway in the church at Grimston in which one descended by several steps, as is often the case on the Wolds. The churches seemed to have been intentionally built below the level of the surface. The chancel was plain early Norman work. The chief glory of the church was its font, which was very massive, being of 38in. diameter, and the largest on the Wolds with the exception of that at Kirkburn, which was of exactly the same size.

The tower at Grindalythe was of the eleventh century. Kilham had a fine, rather late Norman south doorway. He was now of opinion that the church at Kirkburn was not built before 1150. At Reighton there was a beautiful square Norman font. There was very early work in the church at Weaverthorpe; it contained early Saxon work. Dealing with Wetwang, he said that there was doubtless a Saxon church there, but there were no remains, as that church was doubtless constructed of wood. The present church was now undergoing restoration and many interesting features were being disclosed. The tower at Wharram-le-Street was very ancient, and there were reasons for supposing it to be of pre-Conquest date, but he would leave that for others to decide. In his opinion, the churches he had mentioned, so far as their existing remains afford a criterion, were built in the following order:—Last quarter of the eleventh century—Wharram-le-Street and Kirby-Grindalythe. Twelfth century (first quarter)—Weaverthorpe, Wold Newton, Little Driffield, Grimston, and Fridaythorpe; second quarter, Wetwang, Kilham, Garton, and Kirkburn; last quarter, Great Driffield.

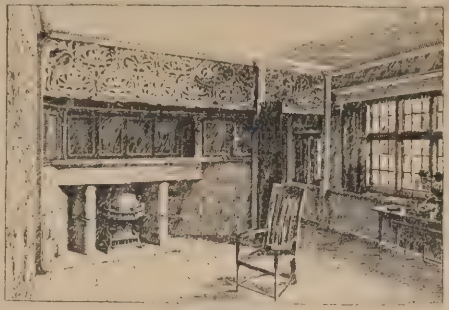
Bricks and Mortar.

APHORISM FOR THE WEEK.

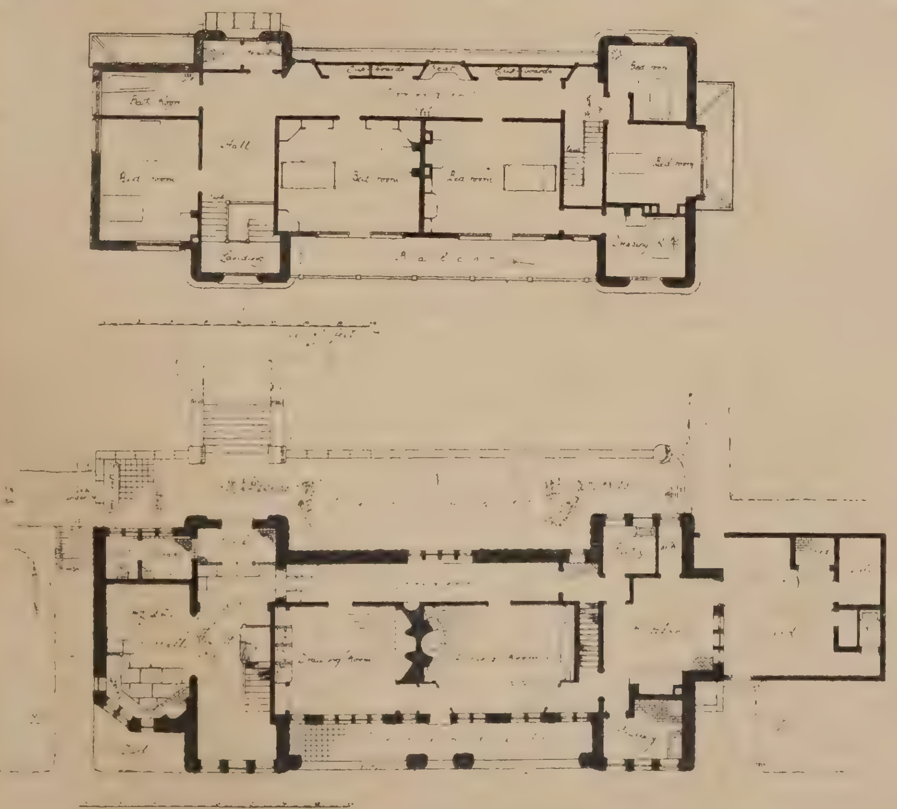
A house is never perfectly furnished for enjoyment unless there is a child in it rising three years old, and a kitten rising six weeks.—SOUTHEY.

Our Plates. "CLIFF TOWERS," by Mr. C. Harrison Townsend, F.R.I.B.A., was designed for a site on the Devonshire coast. The architect started with the principle that each of the rooms should face full south, all leading out of a wide corridor on the north side of the house. This corridor is of sufficient width to allow furniture—such as cabinets—to be disposed along its sides and to permit a fixed seat to be arranged in its window. Both the drawing-room and the dining-room open on to the verandah, not directly, however, but by means of a porch, the double doors of which prevent any possibility of the draught which is the bane of garden doors. The verandah and balcony are treated as integral parts of the house, and not as the flimsy wooden afterthoughts one is apt to see. The bird's-eye perspective and south elevation (see centre plates) show this. The lower part of the fireplace end of the drawing-room, which is illustrated on this page, is intended to be in delicate grey-green Cipolino marble, with the upper part carried out in oak, unstained and slightly waxed. The openwork frieze, in the same wood, is treated with a conventional design, and will have some of its features emphasised by light points of colour; the tips of the leaves, for instance, will be touched with green, smudged or wiped off, so as to leave the greater part of the leaf the natural colour of the wood. The floor will be of pine, stained a light green and beeswaxed. The dining-room will be treated throughout in plain deal panelling painted white, with a mantelpiece of dull copper showing a free use of the hammer on its surface. Oak, slightly beeswaxed, will be used for the floor. The chimney-piece in the hall will be entirely of red bricks with wide mortar joints. The floor here and in the corridor will be paved with the local dark-green paving-stone in large squares. Before leaving the ground floor it should be mentioned that the serving-room occupies the space under the servants' or back stairs, and the sideboard is placed in a recess which will be ceiled at a lower level than the rest of the room, in consequence of the upper flight of the servants' stairs passing over it. The kitchen will be lined inside with glazed bricks of very pale green. With the exception of parts of the drawing-room and dining-room, the use of wall-paper will be avoided throughout the house, plain unmoulded panelling being employed in its stead. The panelling painted white need not necessarily occupy the whole height of the wall, and where it does not, the plaster above may be distempered a quiet tone of clear yellow. Local material is to be used for the exterior of the house. This can be selected of a very soft and interesting green tint, and would harmonise effectively enough with the grey-green Tilberthwaite slates, used also for the battered wall-face on the north elevation, for the towers, and for the roof in general. The gnomon of the sundial, also illustrated on this page, consists of a figure of Time, whose scythe casts the shadow that tells the hour: the inscription would be Austin Dobson's lines:

> "Time goes, you say? Ah, no!
> 'Tis Time that stays; *we* go."

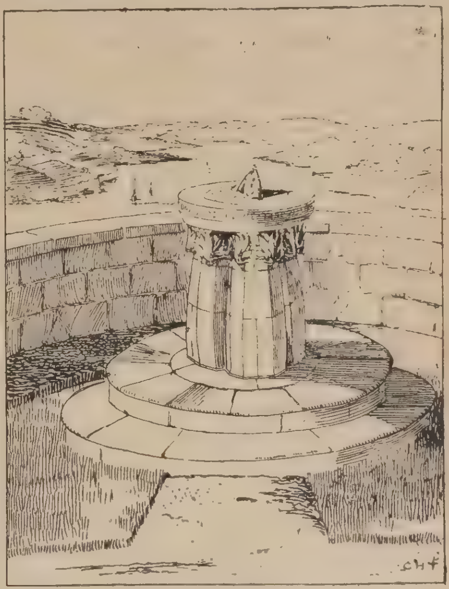


FIREPLACE END OF DRAWING-ROOM AT "CLIFF TOWERS." C HARRISON TOWNSEND, F.R.I.B.A., ARCHITECT.



"CLIFF TOWERS." GROUND AND FIRST FLOOR PLANS. C. HARRISON TOWNSEND, F.R.I.B.A., ARCHITECT.

Decoration of Ship Interiors. IT is only within the last few years that opportunities have been given to the artistic consideration of the principal apartments in a few of the larger "liners." Even now, however, the plan is usually determined before the architect is consulted, and he is merely permitted to treat decoratively certain given surfaces, without having any voice in many matters where his influence would be beneficial. A saloon over 50ft. square and about one-seventh this figure in height is not easily made shapely without supports or screens to emphasise any particular dimension. The personal note is also necessarily absent, and the design must therefore have fuller interest and be more than a background which is satisfactory in most domestic interiors, but beautiful woods and the best of workmanship are at the architect's disposal, and these bear investigation even if some of the artistic qualities are lacking. In the drawing-room of the s.s. *Dunvegan Castle*, by an expressed wish, a motive was adopted from Adams' work. The panelling is of mahogany inlaid with satinwood and pearl. The ceilings are ivory white and gold. The saloon of the *Carisbrook Castle* is in oak slightly fumigated and dull polished. In the staircase of the s.s. *Carisbrook Castle* dull-polished teak is used. Messrs. Niven and Wigglesworth were the architects for Messrs. Donald Currie and Company, and the work was done by the Fairfield Shipbuilding and Engineering Company, of Glasgow. The works are illustrated in our centre plates.



SUNDIAL AT "CLIFF TOWERS." C. HARRISON TOWNSEND, F.R.I.B.A., ARCHITECT.

The Five Architects. IT is interesting at this time to mention briefly the chief works of the five architects who, it is stated, have been chosen to submit designs for the Queen Victoria Memorial. Mr. Thomas Graham Jackson, R.A., was formerly a Fellow of Wadham College, Oxford, and was the architect of six of the existing college buildings of that University, in addition to which he restored the Bodleian Library and the churches of St. Mary and All Saints'. He also designed the new buildings of the Inner Temple and of Rugby and several other public schools. Mr. Aston Webb, A.R.A., was vice-president of the Royal Institute of British Architects from 1893 to 1897. He is the architect for the Victoria and Albert Museum now in course of erection at South Kensington, and he built the Royal College of Science in the same quarter. In conjunction with Mr. E. Ingress Bell he built the Victoria Courts at Birmingham and the Royal United Service Institution in Whitehall. Mr. Ernest George has erected well-known mansions in all parts of England, including Monk Fryston, Yorkshire; Ossington Hall, Nottinghamshire; and several churches. Sir Thomas Drew, of Dublin, is at the head of his profession in Ireland, being President of the Royal Hibernian Academy; and Dr. Rowland Anderson, of Edinburgh, occupies a somewhat similar position with regard to Scotland.

A Glasgow Bank. THE premises of the National Bank, so long a striking feature of Queen Street, Glasgow, are soon to disappear in order to make way for a huge warehouse, which will, we understand, cover the entire site and obliterate the court that at present surrounds the premises of the bank. The front part of the National Bank's premises was erected in 1845.

The building was in more recent times extended by the addition of the portion at the back. The architects were Messrs. Gibson & Macdougall, of Glasgow, and the design is understood to have been specially the work of Mr. Gibson, who later in life left Glasgow and took up his abode in London. The architects of Glasgow, recognising the loss which will be caused to the city by the disappearance of so fine an example of architectural work, are moving in favour of its being transferred to some other site. District libraries are wanted at present by the Corporation, and the bank premises might be adapted for one of them without much difficulty and at comparatively slight expense. The building and the adjoining blocks of warehouse property will soon be in the hands of the contractors, and are scheduled to come down at an early date. If anything is to be done for the preservation of the pile it must be done at once. It is to be hoped that the Corporation will give favourable consideration to the scheme, and save for the city a building which, if not acquired by them, must soon be reduced to mere "building material."

Caretakers of Old London. A MEETING of the committee for the Survey of the Memorials of Greater London was held last week. Mr. C. R. Ashbee, in presenting a brief report of their work, pointed out that they had concentrated most of their efforts on the parish of Chelsea. Their efforts in regard to the interesting little building in the King's Road known as Box Farm had not been successful, for the building had been demolished; but they had managed to keep some record of it. They had also had something to say in the matter of the proposal by the London County Council to run trams along the Chelsea Embankment, as it was felt by many that the lines should take another course. It had been mooted that a scheme was on foot for the destruction of Dr. Keen's house in Chelsea and for building on the site either a theatre or a music-hall, and he thought that the committee should take what steps they could to prevent any such action being taken. They now had a good collection of drawings and photographs, by means of which they hoped to get the people of London to recognise how beautiful were many things that surrounded them. Sir R. Hunter moved that the first volume of the register of the committee should be formally presented to the subscribers, and stated that it had been published by the London County Council. Referring to the proposed demolition of Christ's Hospital, he said it would be a most serious loss if the site of this charming and interesting building were to be covered by streets and buildings. Every effort should be made to oppose the Bill now before Parliament dealing with the matter in order to rescue from the hospital a certain proportion of the open space and some of the more beautiful of the old buildings. The chairman (Lord Monkswell) said that the matter had been before committees of the London County Council, who were now considering what form their opposition to the Bill should take. It was thought that, if the promoters obtained powers to override the Disused Burial Grounds Act and build over the burial ground, they should at least give up an equal amount of ground as an open space. He mentioned that the creation of the new Historic Building Committee of the London County Council was largely due to the efforts of Mr. Ashbee.

Discoveries in Chinese Turkestan. NEWS has been received in this country of some important archæological discoveries in Chinese Turkestan. The Takla Makan desert, now one vast expanse of sand-dunes, and, during a great portion of the year, the scene of raging sandstorms, was formerly the site of a flourishing civilisation. Dr. M. A. Stein, of the Indian Educational Department, is at the present time carrying out, under the orders and at the expense of the Indian Government, a systematic exploration of some of the ancient sites in this now deserted and desolate region. For a number of years past it has been recognised that this old civilisation was, to some extent at least, of Indian origin. To the north of the present Mahomedan shrine of Imam Jafar Sadik, where the river Niya disappears in the sand, the wooden houses and Buddhist monasteries, situated amid the orchards and the avenues of trees, the trunks of which still remain in the ground, have yielded up great numbers of inscribed documents, as well as works of art, household objects, and antiquities of every kind. The art of the clay seals discovered is said to bear traces of Græco-Roman influence, which has long ago been recognised in the sculptures of the extreme north-west of India that have been brought to England in such quantities since the recent military operations on the frontier. There can be little doubt that these discoveries will prove to be of the utmost interest for the early history of Central Asia.

Mr. Harry Furniss on Public Statuary. WHEN opening the seventh Free Picture Exhibition at West Ham, Mr. Harry Furniss criticised the statues and monuments which were placed in the streets and public places of our great towns. The question of their style was raised at a great and solemn public meeting at the Mansion House on the previous Tuesday, when Sir William Harcourt said:—"We have much to be proud of and to be thankful for, but I do not think we can boast of our monuments. This we believe to be an age of progress, and it is more necessary that we should progress in our capacity for monumental commemoration. I hardly know of one that, even in this great metropolis, the greatest city in the world, is deserving either of the greatness of the Empire or the greatness of the city." He himself agreed with those remarks, and would assert that the man in the street had a right to be protected from these ugly masses of masonry and dead black figures which offended the eye generation after generation. The two things which always struck him when he entered an English town where the crookedness of the lamp-posts and the ugliness of the statues. In the end the alteration of these things must be left to the man in the street. He could not see where the satisfaction came in for worthy members of society to have their ugly figures dressed in badly fitting clothes put up in public places and handed down from generation to generation. There was little doubt that favouritism was directly responsible for a great deal of the bad work in our public streets, and he might be permitted to give it as his opinion that that would be the rock on which this great proposed memorial to the Queen about which they heard so much would split. They were at present on their mettle, trying their best to show the world that they could at least produce one memorial worthy of this great country, but that would never be arrived at until it was open to everybody, no matter in what walk of art, to send in suggestions or models which might be submitted to public view and the public judgment taken upon them.

A Drastic Committee. HE wanted to revolutionise the whole of the monuments and statuary in England; he wanted a committee formed which he might call the "public art reform committee," and that committee should go through not only London, but the whole country, and report upon the statues which ought to be underground. They might keep some statues as pillories to public men, and not as monuments to their memory, as was at present the case. It might be well that some of the houses in which celebrated men had lived should be preserved. At the present time there was some hesitation about Hogarth's house, and it would be a great shame if it were not preserved and acquired by the nation. But in the matter of their public monuments more taste and regard for congruity should be observed. For instance, Cleopatra's Needle was as much out of place on the Thames Embankment as a London omnibus would be on the banks of the Nile. It was by such exhibitions as the one he declared open that they were educating the East-ender to teach the West-ender something in the matter of artistic taste'

A NEW HOSPITAL AT HALIFAX.

A NEW HOSPITAL has been erected at Salterhebble by the Halifax Board of Guardians. The hospital stands on a site of about twelve acres, about a mile from Halifax on the Huddersfield road. Plans have been prepared by the architect, Mr. W. Clement Williams, F.R.I.B.A., of Halifax, for accommodation for 642 patients, in addition to which there are beds for about 100 nurses and servants. The total estimated cost is about £130,000. To meet the immediate requirements only provision for 400 beds, together with the complete scheme of administration buildings, has been made at present. The Nurses' Home contains accommodation for nurses and probationers, including general and separate sitting-rooms, library, dining-room, and lecture-room. There are in this block over seventy bedrooms. Immediately behind the Nurses' Home, the first floors being connected by a three-arched bridge, is the administration block, the ground floor of which is devoted to porters' rooms and store-rooms. The first floor is set apart for committee-rooms, doctors', stewards', and matron's offices and sitting-rooms, dispensing and matron's stores, with electric lift from the basement. There are also a large kitchen and a scullery, with larder, &c. On the south side of this floor is an isolated receiving pavilion connected with the main building by a bridge. On the same storey of the eastern block are the assistant medical officer's apartments. The chief medical officer will be provided with a separate residence. The other administrative buildings are the electric light and power station, placed below the ground level, the boiler-house and disinfecting station, and the laundry.

The buildings already referred to occupy the centre line of the site, which runs from east to west, and the ten pavilions for patients (five for each sex) are placed in two lines, one on the north and one on the south side of this central block. Corridors connect the administrative buildings with the pavilions, all of which are connected by one-storey corridors with service subways underneath them. The subways allow of any pavilion being served from the kitchen or store without the hospital corridors being used. Eight of the pavilions are oblong and two storeys high, while the remaining two are circular, and three storeys in height. Outside the general hospital scheme and entirely isolated are two small pavilions for maternity cases, each containing four beds. The mortuary will also be an isolated building.

A NEW CHURCH AT WALTHAMSTOW.

A UNITED Methodist Free Church at Walthamstow has been opened. The buildings are erected on a prominent site at the corner of Shernhall Street and Oliver's Road, in Early Decorated Gothic style. The church is flanked on one side by a square tower, which rises to a considerable height. A large church parlour is placed alongside the church on the opposite side. The facings are of red brick, with Bath-stone dressings. The roofs are of green slates. Boldly moulded triple arches of Bath stone, supported by Norwegian granite shafts, with carved caps, divide the nave from the apse, where the choir and organ are accommodated. The choir has a traceried stone front, or dwarf screen. The pulpit occupies the space under the central arch, and is the centre from which all the seating radiates (the seats being circular on plan), so that all the congregation immediately face the preacher. The roof is of hammer-beam construction, with open timber spandrils of tracery work. The metalwork is all of wrought iron and copper. The church will accommodate about 750 persons in a mixed congregation, all on the ground floor. Provision is made for a future small end gallery to accommodate about 100 persons. The contract was let to Mr. J. A. Carter, of Grays, Essex, for £5,609. The architects, whose design was selected in competition, are Messrs. George Baines, F.R.I.B.A., and Reginald Palmer Baines, of 5 Clement's Inn, Strand, W.C.

Builders' Notes.

Mr. Johnson, builder and clerk of the works at most of the Board Schools which have been built in Middlesbrough, died last week.

The Development of St. Anne's-on-Sea is still being kept up. The Land and Building Company, early promoters of the town and owners of most of the land, have decided to pay 9 per cent. dividend, and owing to the great yearly increase in visitors, to apply for a provisional order to widen the pier from 18ft. to 34ft., increasing the pier-head area from 1,400yds. to 4,600yds. A pavilion is to be built to accommodate 800 persons. During the year plans for 111 houses and shops were submitted. The opening out on the north-west is expected to produce one continuous town from Lytham to Blackpool.

The Building Trades Exhibition which opens on the 17th inst. at the Royal Agricultural Hall and remains open until the 27th inst., will be the largest and most representative in point of exhibitors of its kind. Every foot of the ground-floor space has been allotted. Special sections are this year being devoted to fire-prevention and smoke abatement. Visits to the Hall, as in previous years, will be paid by professional institutions interested, the date of which will be given in next week's issue. Lord Wolseley is prevented from opening the Exhibition owing to the fact of his being sent as Ambassador to foreign Courts, but Lord Roberts has kindly consented to pay the Exhibition a visit between the dates above named.

Proposed New By-laws for Liverpool.—Drafts of a new set of by-laws have been issued for presentation to the Liverpool City Council. One lot has reference to new buildings, ashpits and the removal of house refuse; and it is therein provided, with respect to the structure of foundations of new buildings for securing stability and for purposes of health, but every person erecting a new domestic building shall cause the whole ground surface or site to be properly asphalted with natural asphalt on a suitable foundation, or to be covered with a layer of good cement concrete, at least four inches thick. Provision is also made with regard to bringing the site up to the level of the surface of the ground immediately surrounding and adjoining it; and as to ventilation it is set forth that six inches of space must exist between the surface of the site and the floor, such space to be thoroughly ventilated by means of suitable and sufficient air bricks, or by some other effectual method.

Slump in the Red Brick Trade.—Building-brick makers in the Oldbury, West Bromwich, and Tipton districts are now passing through the severest crisis experienced for many years. Twelve or eighteen months ago prices of common red bricks were raised to an unusual height by the rapid development of house building, not only in the immediate neighbourhood of the works, but also in London, Birmingham, and other large towns. Prices realised about 34s. per thousand, compared with the normal rate of about 20s. On the strength of the "boom" old brick works were extended and new works opened, causing the production of builders' bricks to reach enormous proportions. The extra demand for slack for the brickworks was an important factor in raising the price of that article from about 6s. to 10s. per ton. The usual result of over-production has followed in the slump now experienced, as most of the chief brickworks in the districts named have been working short time with no immediate prospect of improvement, while prices have been slowly declining for the last three months. Instead of 34s. per thousand the present selling price is anything between 25s. and 18s., and even a lower price is mentioned where large contracts have to be tendered for. Building operations in all the district towns seem to have been for a time suspended by common consent until the price of slack and consequently that of bricks, is further reduced. More than half the present price of bricks is said to be absorbed in fuel, leaving little or nothing for labour and establishment charges.

The Builders' Accident Insurance (Limited) held its twentieth annual meeting at the offices, 31 and 32 Bedford Street, Strand, last week, the chairman, Mr. Stanley G. Bird, presiding. The report, which was adopted, stated that the company had received notice of 1,767 accidents during the year 1900. Although owing to various causes, there had been some falling off in the premium income during the year, the directors were satisfied, from the financial result, that the care which they had exercised in taking and discriminating risks had not been without advantage to the company, which was now in a very satisfactory position. The directors had decided to enlarge the scope of the policy relating to risk of accidents to the public, and also to undertake the driving risk. The Board reported with regret the retirement of Mr. J. C. White through ill-health. The retiring directors—Mr. T. Barnsley, Mr. Woodman Hill, Mr. A. Krauss, Mr. W. Nicholson, and Mr. G. H. Trollope—were re-elected.

THE CHESTER ROWS.

A New Theory of their Origin.

By GUY WILFRID HAYLER.

THEORIES on the origin of the far-famed, picturesque, and historic Rows of Chester have been both many and ingenious. Mr. H. D. Harrod, F.S.A., in a studious paper on the subject (see page 120 of the BUILDERS' JOURNAL for March 20th), says the origin of the Rows must be sought for in Ancient Chester, and that without any great revolution in design or architecture the Rows have developed by a natural growth on the lines of the ancient design of Roman Chester. This seems to be merely a reiteration of the views of Pennant, who has written that "these Rows appear to me to have been the same as the ancient vestibules, and to have been a form of building preserved from the time that the city was possessed by the Romans. They were the places where dependents waited for the coming out of their patrons, and under which they might while away the tedious minutes of expectation. Plautus, in the third act of his 'Mostellaria,' describes both their station and use. The shops beneath the Rows were the *cryptae* and *apothecae*, magazines for the various necessaries of the owners of the shops."

Another antiquary, Ormerod, differs from this opinion and says that he does not think they are so old, but believes that the Rows were erected as galleries, from which the citizens might defend themselves from the attacks of any bodies of cavalry who might have forced the gates, during the wars between the English and Welsh. This is very feasible, as architecture in the Middle Ages was constructed to a great extent on a military and defensive basis. In later times the Rows did certainly act as protective agencies, and the possession of them in the days of the Civil War decided the occupation of the city by either the Royalists or Parliamentarians.

But in my opinion—and I tried to look at the matter from an independent standpoint during a considerable stay in Chester recently—the origin of the Rows is to be looked for in another direction altogether.

It seems to me that the annual procession of the Chester Minstrels and the holding of the famous Chester Plays must have had a great deal to do with the construction of these galleries.

As is well known, these plays took the nature of open-air pageants, and were very similar to the *masques* which are held to this day in many parts of the Continent. They were performed every year at Whitsuntide. A scholarly edition of the plays was published nine years ago by the Early English Text Society.

It does not need great imagination to conceive that if these great spectacles—and undoubtedly they were in many senses *great* in their day—were held annually they must have affected the nature of the buildings of the various streets they passed down.

Year after year as the festival came round the pilgrims flocked to Chester—welcome customers for the inns, hostelries, and shopkeepers. What was more natural than that the citizens prepared for the gala and designed their houses so that they had a gallery for spectators? And this gallery harmonised with the general scheme of architecture, proving a convenient and useful adjunct. It seems one of the most feasible theories to account for the construction of these famous "Rows," the like of which is seen nowhere else in the world. The open-air pageantry and carnivalism of the Middle Ages had every opportunity for display in Chester, and one cannot help thinking that the Rows were constructed as the theatrical galleries of these processions.

A SOLDIERS' SWIMMING BATH AT ALDERSHOT.

A NEW soldiers' swimming bath is being erected just south of the Headquarter Gymnasium in Queen's Avenue. A flight of stone steps leads into the glass portico, from which two glass swing doors lead into the entrance vestibule. This is situated directly under the dome, which is carried on a circular steel ring girder, supported by artificial stone arches springing from the four piers that stand at the corners of the entrance hall. These piers are faced with blue grey and vandyke brown enamelled bricks up to half their height, the top portion being artificial stone. In one corner of the hall a staircase leads up to the balcony that overlooks the vestibule, which is fitted with ornamental iron railings painted peacock green. Beneath the staircase is a ticket office, and opening out of the hall and balcony are storerooms and lavatories. The floor is paved with polished Italian mosaic, and the hall is lighted by numerous windows around the base of the dome. To the right of the hall two sets of swing doors open into the bath. The bath itself is 100ft. long by 40ft. wide, varying in depth from 3ft. 9in. to 8ft. 9in , and is paved with white glazed bricks and lined with white Minton glazed tiles. The bottom is divided into eight longitudinal sections by lines of blue glazed bricks, for the purpose of forming tracks for swimming matches. Around the top of the bath and under the stone edging a scum trough is fitted, which carries off any objectionable matter, and at one end is fitted a perforated pipe for spraying the surface of the water to remove floating particles of dirt, &c. The bath has a capacity of 165,000 gallons, and is filled by a 6in. pipe direct from the main, and is emptied by an 18in. drain. Around the bath are dressing boxes, fitted with seats, foot gratings, and clothes pegs, and in the corners flights of stairs lead to the spacious gallery above, which runs round the four sides of the building, and is fronted with an ornamental iron railing. At the east end the central portion of the railing runs back on wheels, and here will be fitted the high diving board, 12ft. from the surface of the water, the space afforded by the alcove behind giving the necessary run. The bath is lighted by high lantern lights in the roof extending its whole length. A set of tinted fanlights are let into the north wall above the gallery, and, with the lantern lights, give light to the building. Ornamental steel girders support the roof, and are fitted with rings to attach gymnastic apparatus to. From the gallery two sets of swing doors open on to the gallery over the vestibule, giving entrance direct from the road for spectators. The walls in the interior are left of the natural red brick, and the roof is shining white, the ornamental girders light blue, and the gallery railings peacock green. The woodwork is stained dark oak, and the supporting columns are painted Pompean red and white, divided by a black band. Beneath the entrance hall is a boiler-room, fitted with an enormous boiler, nearly 30ft. long and over 20ft. in circumference. This will furnish the bath with hot water, and supply the steam radiators fitted to warm the building. A subway leads round the whole bath, in which the pipes are laid, thus affording the workmen easy means of attending them. The furnaces are connected with the shaft that rises 60ft. behind the building. The architect is Mr. F. J. Smith, F.R.I.B.A., of London, and the builders are Messrs. J. Bottrill & Sons, of Reading.

THE GROUPING OF PUBLIC BUILDINGS IN A GREAT CITY.*

BY C. HOWARD WALKER, F.A.I.A.

THE title of the paper that I have been asked to prepare implies the admission of the fact that buildings of any description gain in effect by being grouped, and that isolated buildings, of whatever individual merit, are insignificant in comparison with massed constructions, even if these latter be comparatively mediocre in quality. It requires but little argument to uphold this statement. Every famous architectural pile in the world testifies to it, and the buildings of modern expositions are additional witnesses. It is, then, a manifest waste of opportunity to erect monumental buildings so far apart from each other that they cannot be seen together excepting from a balloon.

The fact admitted that buildings should be massed, the conditions influencing such massing are next to be considered. Primarily they are

Conditions of Utility.

Buildings are placed where they will do the most good, where they can be the most conveniently approached, and will hold the most practical relations to each other. If these conditions are allowed to act, all public buildings are naturally gregarious. There is one other important factor: that of the avoidance, so far as may be, of the disturbance of existing conditions. From these conditions have resulted the Ring Strasse of Vienna, the boulevards of Brussels, Antwerp, and Frankfort, and the consequent placing of important buildings upon them. The demolition of ancient city walls and subsequent filling-in of moats gave room for municipal improvement without demolition, and preserved a tradition while embellishing the city.

The mediæval city market or meeting-place, whether within or without a citadel, no longer exists as the pulsing heart of a city, for the cities have become of such extent that squares or places must multiply in number. What in the old days was the heart has now become a series of ganglions or nerve centres, connected by avenues, parks, or boulevards. What was formerly a *coup d'œil* has become a series of points of interest which should not have mean approaches. The picturesque masses of castles and cathedrals were the more interesting from the contrasting hovels clustering around their feet, but the dignity of modern civic buildings does not accord with such a setting. The city of to-day has grown too large to be picturesque; its avenues are too broad, its spaces too vast, its distances too great. Accident must give place to intention, or the general effect of the city will be haphazard, incongruous and incomplete. The impression of incompleteness is characteristic of American cities for the reason that, with few exceptions, they have either no initial scheme in plan or a meagre one. There is, it is true, the numbered and lettered gridiron plan of Philadelphia and Chicago, which "grinds down their stones to a pale unanimity," in which all streets are alike and one view as good as another, but such planning can hardly be considered an achievement.

Washington

has a plan of a higher type and greater possibilities, and in spite of the numerous indignities to which it has been submitted, it still gives the city its individual character and much of its undoubted attractiveness.

This plan is based upon centres of interest, not too far apart to be seen from each other, and, therefore, vistas terminate with a monument, sculptural or architectural. This is a very great gain, and exists in only two other cities—Paris and Rome. Nothing is more ignominious than a broad avenue leading to nothing, and fading away at either end into the frayed skirts of a city.

The same mind that first conceived a plan where all streets were alike arose to a loftier height of inspiration and introduced final perfection into his plan by assuming that a very broad, perfectly straight avenue of infinite length was the finest possible street for a great city. There can be no greater blunder in planning. What is more wearisome than endless streets of which the destination cannot be foretold? All scale is lost by too long perspective; and unless avenues are viewed from an eminence or are terminated by an important mass of buildings raised high in the air, it is safe to assume that half a mile is quite long enough for any uninterrupted vista. One of the fundamental principles of architectural planning is that of axes, upon which are strung both the voids and solids of the masses of building. A great avenue is a great axis, a great void, but it should not be that alone; it should lead to the greater solid masses at either end. It is important, then, that the chief buildings should be, not upon the sides, but upon the axes of great avenues, and, in fact, in most cases where the buildings have been first established, the axial avenues have later been constructed by demolition. Unfortunately, the reverse process does not as often occur. The avenue once established becomes a public right-of-way, and there is nothing so repugnant to the Anglo-Saxon mind as to interrupt or interfere with anything which has once become public property. Even bridging a right-of-way is considered an injustice; it must remain open to the stars themselves. Fortunately, in Washington, the necessity for constructing centres of interest on the axes of avenues is not felt. They already exist. The danger seems to be this: that the sides of the existing, or to be created, avenues are held to be adequate sites for new Government buildings, while in point of fact those buildings should be built upon their axes. Unter den Linden, in Berlin, is, in this respect, an excellent object lesson. Despite some admirable buildings upon its sides, such as the Russian Embassy and the Arsenal, this famous avenue is ineffective until one end is reached, when the Brandenburg Gate, a puerile imitation of the Propylæa, is thrown frankly across its axis, and at once dignifies it. At the other end of the Unter den Linden is a marvellous example of purposeless planning. There is prevalent another impression in regard to great avenues, which is this: that a bridge is of greater value and merit than the avenue leading to it, and can be considered as a terminal unit, and that it is of greater importance than the avenue leading to it. As a matter of fact, a bridge is an integral part of the avenue, and counts but little in effect when seen from the avenue.

The Question of Bridges.

The architectural merit of a bridge, which may be great, is seen from up or down the stream. Its artistic value as a monument is entirely due to the uniformity and symmetry of its sides and the contrast of open spaces to high façades, and to the treatment of its approaches. When the bridge is a very long one, any treatment of its centre, far from either bank, is necessarily isolated, and when such treatment is suggested by constructive conditions, as in the case of a draw, it need not be unduly exaggerated. In most cases the merit of a bridge is in its long horizontal reaches, its repetition of spans, and the introduction of perpendicular motives is unnecessary. On the other hand, the ends, or approaches, of bridges admit of admirable monumental treatment, and absolute symmetrical treatment of these approaches is not essential. One of the most effective bridges in existence is the old bridge at Prague, which is most unsymmetrical in treatment. Another is the bridge at Heidelberg. The great towers of the new bridge in London are most picturesque, but the length of the bridge is comparatively short, and the towers are but little isolated from the approaches at the ends. On the other hand, the long bridge at Worms, of a similar conception, is ineffective. The ends of bridges should open into spaces or squares, affording ample opportunity for approach and circulation. It is at these points that excellent sites for the erection of monumental buildings occur. An avenue leading to a bridge need not be considered of sufficient importance to warrant the erection of the chief buildings along its sides. There exists also the river frontage. Buildings upon such a frontage are effective under the following conditions:—

(1) When the stream is narrow and they can be seen from the opposite bank; (2) when they are near the ends of bridges and can be seen from the bridges; (3) when the stream curves, and the planes of the façades are changing to conform with the curve.

In all cases the embankment should be carefully treated on the stream side. A terrace set back from the river, leaving the bank unkempt and rough, abandoned to the accidents of river traffic, is not successful. The Elbe at Dresden is a case in point. It is well, if possible, to have ample space between the façades of the buildings on the river and the embankment, and to keep all wharves and commerce from the frontage, or confine it to defined and isolated points. The treatment of a river-front must be undertaken thoroughly. Half-measures are sure to prove troublesome in the end.

In one essential American architecture has been peculiarly deficient—that is, in

The Monumental Treatment of Grades.

Abrupt changes of grades are not obstacles, but opportunities. We have been abundantly satisfied if our buildings were planted, not set—that is, if the surface were levelled for them and they had no apparent connection with the ground on which they were placed. The Capitol is one of the most admirable exceptions to this fault. There is nothing more attractive than walls, steps, terraces, balustrades, and buttresses, which are integral parts of most buildings abroad, and which, when the natural grades have not given excuse for their existence, have been deliberately created as necessary setting to the buildings.

In our case in Washington there is every opportunity for this class of work, and it is of infinite variety and advantage. It can be made to soften too great austerity of design, and to dignify too great license. In many cases the approaches to a simple inexpensive structure exalt it above a pretentious, but undeveloped, neighbour, and in any scheme for the embellishment of a city too much stress cannot be laid on these important accessories to the higher architectural achievements. Much of the beauty of cities of to-day also is due to judicious laws preventing unsightly structures, especially when these structures are erected by the municipalities themselves. For instance, it is a wise precaution that backgrounds to monuments, sculptural or architectural, should be, so far as possible, agreeable to the eye. There should be, therefore, civic laws which would make it impossible for any large, unsightly building, manufacturing or otherwise, to be erected in proximity to public buildings—that is, the city should have the power of approval or disapproval of the design for such proposed buildings. At present there is in Dresden a large power-house with a huge yellow chimney, being built directly behind the great opera-house, of which Dresden is so justly proud, and which was Gottfried Semper's best work. The Dresdeners have erected a statue to Semper in the square, but they have permitted this intolerable structure to dwarf everything about it.

In Berlin the great war-monument to the Emperor William has for a background a cheap furniture establishment, covered with signs, and a red and yellow brick industrial school. It is proposed to paint out the one and tear down the other, both of which would have been unnecessary if the monument had been well placed. If a monumental avenue is established, it would be well to follow the example of Buda-Pesth in relation to its great Andrassy Strasse — that is, there should be specific laws passed in relation to the façades upon the avenue as to height and character, and the existence of unsightly party walls should be made an impossibility. If possible the city should have similar control of the corners at the crossing of all great avenues, and of buildings upon the axes of great avenues. A final, apparently minor, detail is of the utmost importance.

Every city should control the designs and location of all flag, gas, electric, and trolley poles, of all kerbs and drinking-fountains, of all signs beyond a specified size, and of all kiosks. Many beautiful streets and buildings in foreign and our cities are made hideous by signs and kiosks.

---

* A paper read before the thirty-fourth annual Convention of the American Institute of Architects.

These restrictive laws would be specific laws for specific and worthy purposes; they would be unjust to none, and calculated to appreciate rather than to depreciate real estate. Accident and disorder went far to make the picturesqueness of the ancient city. Its time has passed. Order and restraint are essential to the beauty of the modern city.

Thus far are general considerations applicable to all cities. It is now a question as to their direct application to Washington, in order to make it compare favourably with the great capitals of the world. Let us see what those capitals have done with their opportunities. In most cases they are upon rivers, and have taken advantage of the river-banks. In many cases they were walled cities, and when, under modern conditions, these walls were removed, their places have been taken by boulevards encircling the centre of the city. In either and in both cases public buildings have been placed upon the river embankments and upon the boulevards; in all cases bridges have been made monumental. In addition to this, eminences have always been considered as fitting sites for the most noble buildings. In most modern cities in Europe the condition enforced by the already existing remains of the past has made a comprehensive scheme of treatment difficult, and the most that could be done was to make the best of possibilities. Paris and Buda-Pesth are perhaps exceptions; in both cases nothing has been allowed to interfere with a broad, well-studied scheme. Overcoming obstacles and adapting conditions are very apt to add an additional charm to results, and to produce a more attractive, though less formal, city.

What some Cities have Done.

The different capitals of Europe have treated their problems as follows:—

London has chosen to make its river embankment and bridges its chief monumental feature, its great secondary feature being its parks. In no case are there fine vistas or impressive avenues in London, if we except perhaps Waterloo Place and the Duke of York's Column. The river-front is its great architectural effort.

Berlin has ignored its river, the Spree, which, while insignificant, could have been made attractive. There has been an effort made at the bridges. The great avenue, the Unter den Linden, is effective when it broadens before the Brandenburg Gate, which is thrown across it. At the other end it spreads into a waste of squares upon which the Opera House, the Palace, the Cathedral, and the old Museum are placed with little regard to grouping. As they are, however, all-important buildings, they make a very effective showing despite their careless arrangement. Outside the Brandenburg Gate is a long, wooded avenue leading through a park to Charlottenburg. At a little distance from the gate, crossing it at right angles, is the new Seiges Allée, or Avenue of Victory, with 16 exedras on either side, with a marble figure of a Prussian ruler in each, and on either side of the statue busts of his principal subjects. The avenue leads up to the Column of Victory, which is in the midst of a great circular place, on one side of which is the new theatre, and on the other the new Reichstag. The scheme of this avenue is fine, but it is somewhat disconnected from the city plan.

Dresden.—Here there is an effort to make the river effective. On one side is the new Finance Building, on the other the beginning of the Bruhl Terrace, with the façades of the Arcadneun and the Art Building The bridges are fine. The commerce of the river has been allowed to remain between the terrace and the stream, and the effect is the effect of incompleteness. The group of great buildings in the Schloss Platz, the Cathedral, Museum, Opera and Palace, while having little relation to each other, and no consistent scheme of plan, are like those in Berlin, from their importance and the fact that no mean environment appears, most effective.

Madrid.—The river is unconsidered; the Palace alone is well placed and effective.

Rome.—The river is now being edged with embankments and boulevards which some day will be attractive. The bridges are strong, vigorous, and effective. The magnificent scheme of approach to St. Peter's, one of the greatest architectural *tours de force* in existence, is too well known to need long description. The equally fine Plaza del Popolo, with the Pincio at one end and the new bridge leading to a long avenue and to St. Peter's, is the second great piece of architectural planning in Rome. All avenues in Rome have a terminal group of buildings, and its vistas are extremely fine.

Buda-Pesth is exceptional, inasmuch as it is essentially a modern city, and has been laid out upon a well-devised scheme, especial attention having been paid to the river-front and to the bridges, and a great boulevard, the Andrassy Strasse, being carried out to the pleasure parks. Upon the embankment only large and important buildings have been erected, with long façades in fact, in the entire length of the river-front, over a mile in length, there are but 23 façades, so that the importance and length of each can be imagined. In addition to this, the embankment is planted with trees, and is devoted to foot passengers only, carriages being stopped at the points where the streets and avenues debouch on the embankment. On the opposite side of the river, in the old town of Buda, rises the Palace, terrace after terrace, finely placed and set.

The Andrassy Strasse has harmonious buildings its entire length, there having been control of the design of the façades by the municipality.

Brussels.—The old mediæval square is one of the finest in Europe, but it has no connection with the plan of the modern city. There are two sets of boulevards—one around the city, occupying the site of the old walls, the other across the city, where the old canal formerly served for commerce. The other set is too far from the centre to be important. The cross boulevards are about thirty-five years old, and prizes of from 1,000 francs to 4,000 francs were offered for the best designs for façades. Many buildings were built from these designs, and the result is pleasing but not especially monumental. There are few effective terminations and vistas. The far-famed Palais de Justice, one of the largest buildings in the world, and certainly one of the worst architecturally, is well placed on an eminence, but with very poor approaches—bare and crude. The great Rue Royale leading to it has some good façades upon it, but they are juxtaposed to badly-designed mercantile buildings, and there is therefore no effect of *ensemble*, as in Berlin, Dresden, Vienna, Paris, or Buda-Pesth. The Palace is on a parked square, and is mediocre.

Frankfort.—Another city with interesting ancient central square, now left at one side, new boulevards taking the places of old walls, and in other respects a city of broad avenues with occasional monuments and fountains; not especially interesting.

Florence.—With its fine mediæval square apart, new boulevards instead of its walls, but without interesting buildings upon them, but with excellent bridges and good embankments on the river Arno.

Prague.—Apart from occasional old buildings, its entire interest centres upon its embankment, its fine bridge, and the magnificent situation of the Cathedral and Hradchin, or palace, on the heights across the river. The cathedral is not a great one architecturally, and the Hradchin is commonplace to the last degree, but their size and situation make them most impressive. The bridge is very elaborate, with end towers and arches, and heavy buttresses and high groups of statuary on its sides. It is extremely monumental.

Vienna has not made much of the embankments of the Danube, though work to that end is now in progress. On the other hand, its Ring Strasse, a very broad boulevard around the city in place of its former walls, is a very fine performance. All the principal buildings are on this Ring Strasse, and as its direction changes every few thousand feet, they are seen at the ends of vistas and at all points of view. They are vast in dimensions, and in most cases fine in design. The famous Prater is a great avenue through a wooded park, and, like all others of its class—such as the Avenue du Bois de Boulogne, the Thiergarten Avenue, the avenue at the Hague, the Cascine in Florence, &c.

Paris has taken advantage of every inch of its river-bank, and by the fine scheme of the Champs Elysées and the gardens of the Tuileries terminating at one end in the Arc de Triomphe and at the other end in the Louvre, and by the series of radial avenues from the Arc de Triomphe and the Avenue de l'Opéra, has created a series of architectural vistas unequalled in other cities. The restrictive laws in regard to buildings and the careful control of designs of monumental work in Paris is greater than elsewhere, and the effect is manifest in the streets of the city.

It is apparent that the most attractive cities are those where some broad and comprehensive plan of treatment has been conceived and adhered to, and where, if poor surroundings or inferior architecture forced itself into prominence, its effect was minimised either by planting-out with trees or by interrupting continuous vistas by a monument or building. Also, that in many cities the most attractive feature is merely a collection of the most important buildings, even if these are not planned in relation to one another. It is not necessary to be enamoured with the idea of magnificent distances. It is not within the capability of human effort to make all things in the range of vision agreeable to the eye. Let us minimise the difficulties and shorten the range of vision. A great city resembles an articulate animal: it is made up of a number of parts jointed to each other. It grows in that way. Each part must, however, be complete in itself, though subordinate to the general scheme. Let us apply this reasoning to

Washington.

By looking at the old plan of the city it is seen that there was a marked and definite initial scheme. Two great centres were created, one the Capitol, the other the White House; from these radiated the avenues, like spokes of a wheel. The main axes, however, of these buildings, which were at right angles to each other, were broadened into great parks extending west from the Capitol and south from the White House to the river—the park from the Capitol being naturally much larger than the other. It was manifestly first intended to erect important public buildings upon either side of this long park; in fact, they are indicated on the plan. This would have created a great National Court of Honour. In some ways it may be regretted that this scheme was not carried out; in others it may be the better in the future that it was not, as the plan was unnecessarily formal and uninteresting. There was, apparently, never any well-considered treatment at the crossing of the axes of the parks. At present the great monument is, then, not exactly on either axis, but sufficiently near for all purposes. The scheme went entirely to pieces when it approached the water-front, undoubtedly for good reasons, as the water-front was not established. This great scheme is still the base for the architectural treatment of Washington. It cannot be ignored. It is perfectly apparent from both the Capitol and Executive grounds and from the river. What up to this time has been done with it? It is perfectly evident that the original intention was that the White House should terminate the vistas of New York and Pennsylvania Avenues, which vistas are now closed by oblique views of the Army and Navy Building and the Treasury Building.

The Chief Architectural Problem

is, without doubt, at the crossing of the axes of the Capitol and of the White House. Here should be the nucleus for future architectural effort, and the Monument is sufficiently great and simple to be in nowise injured by the proximity of buildings. The White House vista will extend to the river; the Capitol vista may or may not, as conditions will decide. At at events, the axis will be cut across in some way at the continuation of Seventeenth Street. Between Seventeenth Street and the river, westerly, may be left as park-land, securing an uninterrupted and extremely effective view of the new monumental bridge. If buildings should be erected on this land, they should be so placed that they will not intercept the view of this bridge from the Monument grounds.

In every American city, without exception, the effect of the public buildings has been lost by their separation and isolation. This is as true of colleges and institutions as of Government and municipal buildings. The power of correlation of co-operation is as great in artistic effect as it is in practical action. There is a close relation between æsthetics and mechanics, and they have been too long divorced

The concentration of the chief buildings of a city in its acropolis or market-place is what has made the architectural grandeur of Athens, Florence, Venice, Buda, Moscow, and Paris. Imagine the grouped buildings of these cities separated and isolated in obscure places, and you go far to destroy the wonders of the world. On the other hand, imagine, if you can, the isolated best buildings of New York or Chicago, or of Washington, brought together into one group, and incongruous as they might be, they would be worth long travel to see. This, however, it is impossible to compass, but it is possible to consider the fact in future building, and it is also possible to unite existing buildings by arcades, colonnades, or even formal avenues of trees with balustrades and sculpture. It is a mistake to consider these of secondary importance. And we should not too much eliminate foliage. Only the great arteries of a city require unobstructed street surface. Elsewhere boulevards and squares are all the better for having grass and trees, and such planting and setting in connection with public buildings is most attractive. There is, as we know, an unusual opportunity to make our capital compare with the other great cities of the world the will is not wanting, neither do I believe i the ability to secure the wished-for result.

WORKING-CLASS DWELLINGS FOR SUNDERLAND.

THE Sunderland Corporation propose to erect dwellings for the accommodation of people displaced by the demolition of slum property in what is known as the "hat-case" area, and have advertised for tenders. Tenders have been invited before, but it was found that the lowest offer was £7,000 in excess of the estimated cost of the buildings. It was not considered advisable to incur this additional expenditure, which would mean the charging of higher rents for the houses; and therefore, in order to reduce the cost, the plans were modified. The abandonment of concrete floors has effected a saving on the estimate of about £2 000, and the substituting of cement for white-glazed facings on the staircases means a reduction of about £1,200. The buildings will consist of three blocks, each three storeys in height. The first block, 165 ft. long by 80 ft. broad, will contain six double-fronted houses, with rooms on each side of a common staircase, there being six rooms on each floor, divided off into tenements. The second block, 126 ft. long by 72 ft. broad, will be similarly arranged for six three-storey double houses. The third block, the smallest, will measure 70 ft by 40 ft., and will consist of three three-storeyed houses. The living-rooms will measure about 16 ft. 6 in. by 12 ft. 6 in., and the bedrooms 12 ft. by 12 ft. There will be one large common yard for each block, these being intended for playgrounds, drying spaces, &c. There are to be sculleries and conveniences—with water carriage—on each floor of all the buildings. Each block will be in charge of a caretaker, who will be held responsible for the order and cleanliness of the tenants. As to the rents, it is intended to charge 4s. 6d. per week for three-roomed tenements, and 3s. 6d. for those of two rooms. It is not decided yet whether or not any portion of the buildings shall be let off in one-roomed tenements.

A new Jewish Synagogue at Glasgow is being erected in South Portland Street. The architect is Mr. J. Chalmers.

A new Foresters' Hall at Dundee.—A large hall in Rattray Street is to be erected for the Dundee Courts of the Foresters' Friendly Society at a cost of £8,000. When the whole scheme is completed it is estimated to cost about £14,000.

TALLEYRAND'S CASTLE.

THE Castle of Valençay, the ancestral home of Prince Talleyrand and the place of exile for six years of Ferdinand VII. of Spain, situated on the Tours-Vierzon line of the Orleans Railway, is to be put up for sale, by auction, next month in Paris, at the upset price of £104,000. The estate is the joint property of the heirs of the late Duke of Talleyrand, Valençay, and Sagan, and its time distance from Paris is now about five hours, but by a new line which is being built it is anticipated that the journey will be shortened by about an hour. Among the lots comprised in the sale are the castle and its dependencies, the park, and the forest of Gatines. The castle is a magnificent Renaissance château, and after the forced abdication of Charles IV. of Spain in favour of his son Ferdinand, the Crown Prince, and the occupation of the Spanish capital by the French troops under Murat, Ferdinand having renounced the Crown of Spain unconditionally, it was assigned to him as a residence along with his brother Don Carlos, his uncle Don Antonio, his preceptor Canon Escoiquiz, and the Duke of San Carlos, an annual income being provided him from the Crown revenues of France. At Valençay he remained until in 1814 he was placed on the Throne of Spain after the splendid victories of the British in the Peninsula had compelled Napoleon to evacuate the country.

QUEEN VICTORIA MEMORIAL.

WHAT MR. LEONARD STOKES, MR. BENTLEY, AND MR. SETH-SMITH THINK OF THE SCHEME.

A FEW prominent architects have given to the Press their opinion on the decision of the committee in regard to the Queen Victoria Memorial. The president of the Architectural Association, Mr. Seth-Smith, while anxious to say nothing against the chosen few, was unhesitatingly of opinion that the list did not even approximate to the best men, and that the limitation to five was disastrous.

"It is necessary to have a very much wider field," he declared, "before a really worthy memorial can be secured. In the first place, sketch designs should have been invited from a large number of architects, and these should have been adjudicated upon by a strong committee of assessors. Once they had agreed upon a sketch design, the successful competitor should be paid a substantial fee, and then he and half-a-dozen other selected architects should be invited to elaborate the design, and work it out in detail. Then we should in all probability have seen a memorial worthy of the occasion."

A similar idea for preliminary sketch designs was expressed by Mr. Leonard Stokes.

"Have an open competition in the first instance," he explained, "confined to sketch schemes, so that the committee can decide whether the memorial shall take the form of a Marble Arch, or a Nelson Column, or an Albert Memorial, or whatever they think the most suitable; and when that is settled then would be the time to select a few men to develop the idea. I confess that, along with others, I was very disappointed when I saw what the committee had done, and I may say, further, I was disappointed in the names they have chosen. It is not necessarily the busiest men who are likely to produce the best design. Personally, I think we want something very dignified and very classical in line, and without saying a word against the five gentlemen selected, I do not think they belong to the strictly classical school."

According to Mr. J. E. Bentley, the architect of the new Westminster Cathedral, the proposed monument requires more of the art of the sculptor than the art of the architect. He inclined to the belief that the work would be better done had one man been selected by the President either of the Royal Academy or of the Royal Institute of British Architects. The Law Courts and the Foreign Office had been selected in competition, and these, he declared, were architectural failures, whereas the new Government buildings about to be erected in Parliament Street and Whitehall were much more successful in design, because one person had been selected to give his best to the work.

At a meeting in Birmingham on Wednesday last a letter was read from the Lord Mayor of London intimating that half-a-million of money would probably be needed for the memorial.

WARD WINDOWS.

By ROBERT W. CARDEN, A.R.I.B.A.

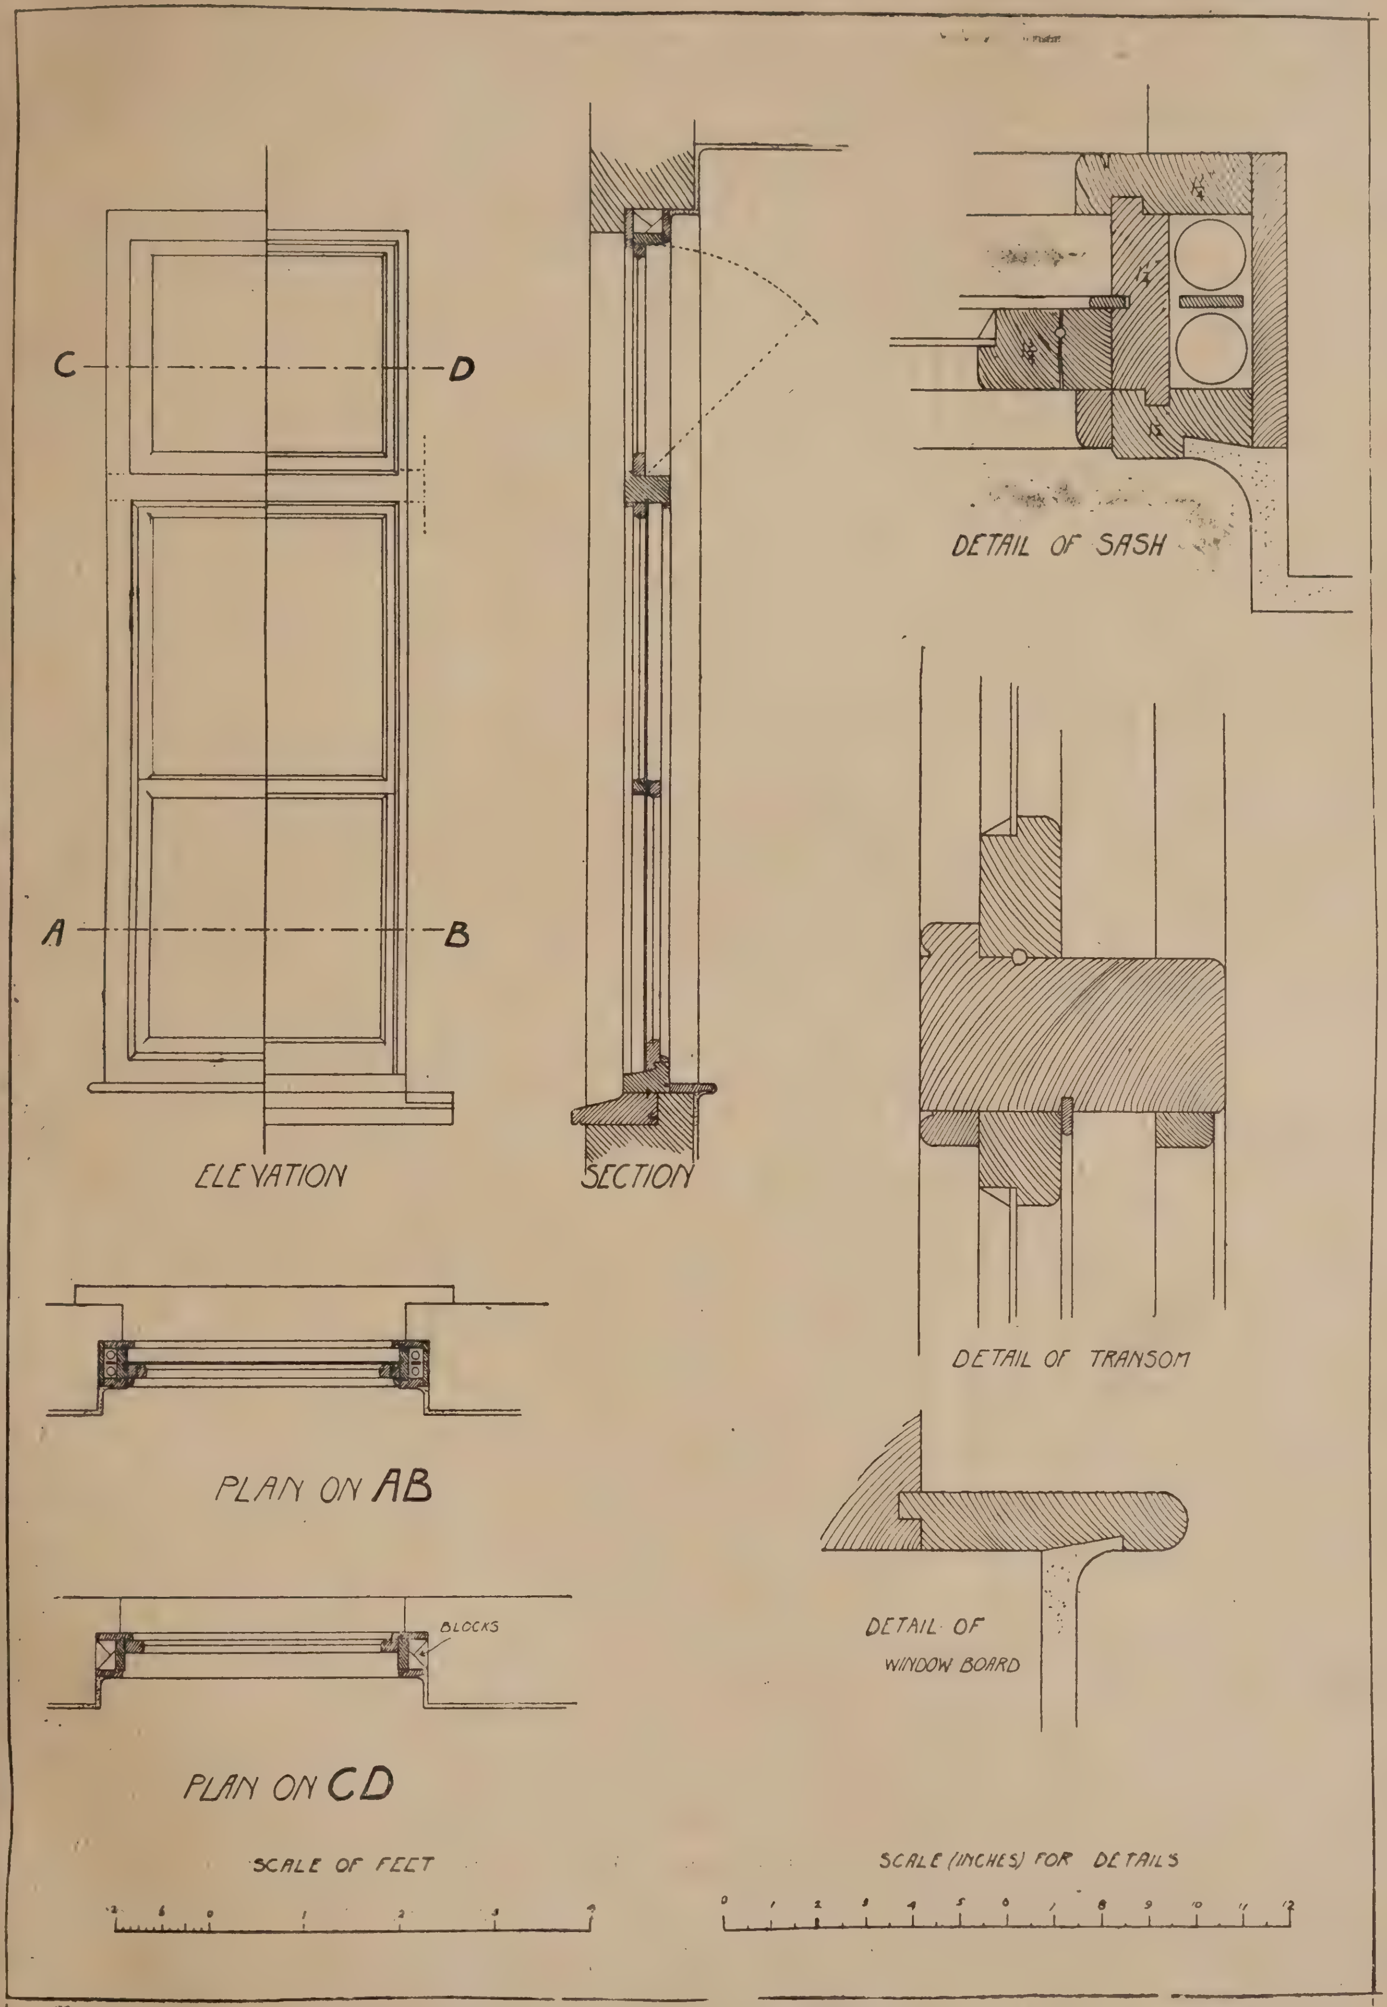
IN the whole range of architectural detail there is scarcely anything so beset on all sides by restrictions as the window of a hospital ward. Greater care in fitting is required than in any other branch of the joiner's work, for while it is necessary, as well as natural, to endeavour to give as refined an appearance as possible, yet there are requirements in the matter of mouldings and enrichments which condemn such details to have a more or less poverty-stricken appearance; while draught and damp have to be more vigorously excluded than anywhere else. It is usual in wards and in their lavatory blocks to round off an angle wherever it may occur: the angles between the floor and the wall and between the ceiling and the wall are carefully curved so that there may be no possible lodgment for dirt and its concomitants, and the angle formed by two adjacent walls is also usually rounded off, though there is not the slightest need to round an external mitre, as there can be no question of its forming a collecting ground for disseminating disease germs.

This principle of "rounding" everything of course applies to windows and all other joinery. But more than that, the window is practically restricted as to its dimensions. If a ward be 13ft. high and the sill be placed 3ft. above the floor-line, the window must be 9ft. high, for it should run as near the ceiling as possible and the remaining foot is required for constructional work. The space between the beds of a medical or surgical ward is usually about 4ft., and this again limits the width to about 3ft. Finally, expert opinion has fixed the type of window that shall be employed, for a double sash hung with a "reversible" patent and a fanlight over is the form usually adopted; and wisely so, for the sashes are easily and quickly cleaned, and the fanlights are of use as an aid to ventilation.

In the window shown by the accompanying illustrations, care has been taken to avoid any mouldings that might be capable of retaining dirt. There is no architrave, and the plaster is worked round to a curve and stopped in a rebate in the lining. The sashes themselves are fitted with the N A.P. patent reversible fittings, and can thus be easily reached for cleaning. The glazing should always be in large sheets, and preferably of plate glass, for with small panes the many sash bars decrease the light, break up what view there may be—and it should be remembered that the outlook is a valued possession to a patient who is condemned to sit or lie back all day and do nothing—and afford a number of extra crannies where disease-bearing particles may collect; they also defy with impunity the dusters and dusting brushes of an army of ward-maids. There must, of course, be four corners in every sash (unless an angle-piece were let in), but there need be no more.

Doors and other fittings for wards and lavatory blocks are to a large extent governed by the same requirements.

A Sinking Library.—The Brunner Free Library and Museum, which were presented to Northwich by Sir John Brunner, M.P., is subsiding owing to brine pumping. The architect, in a report on the matter, states that there is a general subsidence throughout the entire building, and in some places the floors were 12in. lower than at others. He is of opinion that the west wall is dangerous and should be rebuilt on the composite principle. To merely make the building safe will entail a cost of £250, while to place the structure in a fair state of repair will necessitate an expenditure of £450.



WARD WINDOWS. BY ROBERT W. CARDEN, A.R.I.B.A.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Arrangement of Hot-plate.

RIPLEY, DERBY. — AIR SPACE writes: "Please describe an arrangement for a hot iron plate for cooking. I do not quite understand the arrangement of flues and stoke-hole."

An ordinary hot-plate in a large establishment is an iron oven kept hot by steam pipes passing through it, but one for cooking would be a "kitchener" such as every new house in London is fitted with, the size depending upon the circumstances. The Eagle range is one of the best, but of course somewhat expensive; cheaper makes can be obtained by enquiry at the ironmonger's. They are made for either brick flues or iron; the latter are best.

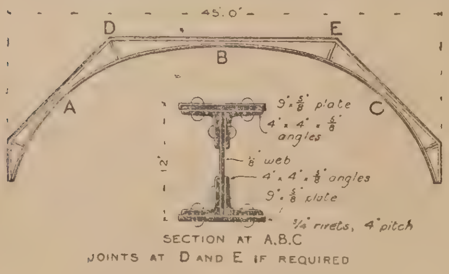
HENRY ADAMS.

Strength of Iron Roof Principal.

CROYDON. — STUDENT writes: "Kindly explain the method of ascertaining the dimensions of the iron principals on enclosed sketch (not reproduced)."

The distance apart of the trusses is not given, but assuming it to be 10ft. or 12ft., the minimum section of wrought iron or steel rib should be as shown in accompanying section, the same section being provided at the top and at the haunches. If the rib is required to be made in pieces for facility of erection the joints should be in the wide part, where the stress is least.

HENRY ADAMS.



IRON ROOF PRINCIPAL.

Books on Plastering, Ironwork and Masonry.

SOUTHPORT.—JOINER writes: "Please recommend a book dealing with plasterer's work, ironwork and masonry, this last giving the names of the various building stones in general use, and their respective qualities."

Millar's "Plastering, Plain and Decorative" (18s. nett.); Adams' "Structural Ironwork" (7s.). We know of no work adequately dealing with both practical masonry and building stones: it would be best to obtain Purchase's "Practical Masonry" (6s.) and Hull's "Building Stones" (7s. 6d. nett). These books can be obtained from Mr. B. T. Batsford, of 94 High Holborn, W.C.

Stone slated Roofs.

BOLTON.—X. Y. Z. writes: "What is the strength of spars necessary to carry stone slates where the purlins are spaced 7ft. apart, centre to centre, and are 15ft. long over part of the building and 12ft. 6in. long over the remainder. The ends of the roof are hipped. Kindly also state sizes of purlins and hips. The outside dimensions of building are 66ft. × 28ft. Is it best to fix stone slates with oak pegs on sawn battens and shoulder up in hair mortar? Is it advisable to board the roof underneath the stone slates?"

A king-post truss may be employed for a roof of 28ft. span, in which case the scantlings of timbers should be somewhat as follows:—Tie beam, 10in. × 4in.; principal rafters, 6in. × 4in.; king-post, 5in. × 4in.; struts, 4in. × 4in.; purlins, 8in. × 4in.; common rafters (or spars), 5in. × 2in. (or 4in. × 3in. if preferred); wall-plate, 5in. × 3in.; pole-plate, 4in. × 4in. Or if a queen-post truss be preferred, the tie-beam should be 9in. × 4in.; principals, 6in. × 4in.; queen-posts, 5in. × 4in.; struts, 4in. × 3in.; straining-piece, 7in. × 4in.; sill-piece, 4in. × 4in; purlins, 7in. × 4in.; spars, 5in. × 2in.; wall-plates, 5in. × 3in.; pole-plates, 4in. × 4in. The purlins at the hips would be the same as in the rest of the building. The best method of fixing stone "slates" is by oak pegs to $1\frac{1}{2}$in. × $\frac{1}{2}$in. sawn oak laths spiked to the spars—if deal laths be employed they should be slightly stouter. For this kind of covering the roof should have a pitch of not less than 45deg., and the "slates" should be laid to a lap of 3in. and "shouldered up" in lime and hair mortar, the tops only of the slates—say 2in. to 3in. from the head—being bedded. Boarding under the slates with $\frac{3}{4}$in. or $\frac{7}{8}$in. rough boards is not much more costly than merely battening, and tends to equalise the temperature of the building and to keep out driving snow.

G. S. M.

Ancient Lights.

BRADFORD.—J. J. writes: "I am desirous of erecting a bath-room over the present scullery of the house marked B on the accompanying sketch. At the same time I am anxious not to interfere with the lights of house A. Do you think I would be within my rights if the work were carried out as shown, giving an angle of 45degs. from scullery window?"

Unfortunately the angle of 45degs. has nothing to do with the matter, in spite of the very generally received impression to the contrary. If the dominant-owner's light has been in existence for nineteen years and a day without interference or obstruction, then it is an infringement of right to block up any part of it. In the present instance the loss of light to the scullery which would be occasioned by the new bath-room would be slight and the material assessable damage inconsiderable, having regard to the purposes for which a scullery is used. The top of the scullery would lose much more light than would the floor, and if the upper part required a good light, or if it were a work-room of considerable depth needing to be well lit at the back, a good claim for damages might be maintained. As it is, the window in the back of A's house seems to suffer more than the scullery window, and it would be well to come to terms with A before commencing the additional works rather than to risk the loss of even a farthing damages with the expense and trouble which a lawsuit or arbitration would entail. The accompanying diagram (the top one of the two) shows more clearly what amount of light the new work would deprive A's scullery of, both at top and bottom.

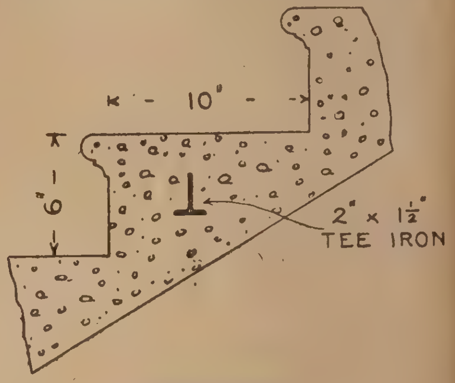
ANCIENT LIGHTS.

Strength of Steps, Joists, &c.

LONDON, W.—DE WET writes: "In constructing a staircase of concrete steps on the cantilever principle, what size iron joist must I put in each concrete step? The steps are 12in. by 6in. by 3ft. 6in. wide, with a 9in. bearing on wall, and are used in a school. Please give a rule for finding size of joists for an ordinary dwelling-house, no ceiling joists being used. What is meant by a fixed girder: does it mean one bolted to template? What is the difference in strength between a riveted girder and a bolted girder (if any)?"

A 2in. × $1\frac{1}{2}$in. T-iron is sufficient to insert in concrete steps, as shown by the accompanying illustration. Although it would be possible to calculate the strength, it is not usual to do so. The common rule for joists is depth in inches = $\frac{1}{2}$ span feet + 2. Example: say 14ft. span, $14 \div 2 = 7$, $7 + 2 = 9$, and thickness = $\frac{1}{3}$ depth; therefore 9 × 3 joists. A fixed girder strictly means one with the ends so built in that the bending down in the centre by the action of a load produces tension in the top flange at each end of span, instead of the usual compression. A riveted girder would always be used where it was necessary to build up from one or more pieces, but occasionally rivets have to be left out for connections, and bolts are used instead to save riveting on the works. These bolts should be a driving fit in the holes and are then practically as good as rivets.

HENRY ADAMS.



CONCRETE STEPS.

How to Become a M.Inst.C.E.

DUNSTON-UPON-TYNE. — PUNGENT ODOUR writes: "Can you state what course of study I must pursue, or to whom I must apply for particulars, in order to become a member of the Institution of Civil Engineers? I hold a certificate for building construction and one of the Sanitary Institute. Will it be necessary to go into the office of a civil engineer, or can I manage it by reading alone?"

All particulars can be obtained from the Secretary, Institution of Civil Engineers, Great George Street, Westminster, S.W.

Chimney Stacks.

LEEDS.—N. W. writes: "In the illustrations to the article on 'Chimney Stacks' in your issue for March 6th, and also in the correspondence referring to it in your issue for March 20th, the majority of the flues are shown 9in. square The building regulations in this city require all smoke flues to be 14in. × 9in. and I shall therefore be glad to know whether in London or any provincial city these flues are allowed 9in. square, as it seems to me that this size is amply sufficient, especially for cottage bedrooms in which fires are seldom made, and being much larger than flue pipes from closed stoves, which have to pass an equal quantity of smoke."

Neither the London Building Act nor the Model By-laws place any restrictions upon the size of flues, with the result that 9in. × 9in. flues are in almost universal use throughout the country, this being the size which is most easily cleansed by the sweep's brush. To build flues 14in. × 9in. is to invite chimney fires, as a considerable amount of soot is generally left behind after sweeping. R. W. C.

Timber Bridge.

London, S.W.—Constant Reader writes: "Kindly give particulars of a wooden bridge for a span of about 50ft., supported on piles driven into the bed of river, to carry a moving load of 10 tons and to have a clear way of 10ft."

It would be necessary to make a survey of the site, and to know the nature of the soil and more about the loading before a design could be submitted. It is a case for a specialist, and the design would be worth $2\frac{1}{2}$ per cent. on the cost of the work. It might have to be timber only, or timber and iron according to circumstances. Also the construction would vary if in this country or abroad, where only native labour could be obtained. The span is mentioned as 50ft., with piles in centre, leaving it uncertain whether there are two spans of 50ft. or two of 25ft. HENRY ADAMS.

Makers of Fireproof Theatre Curtains.

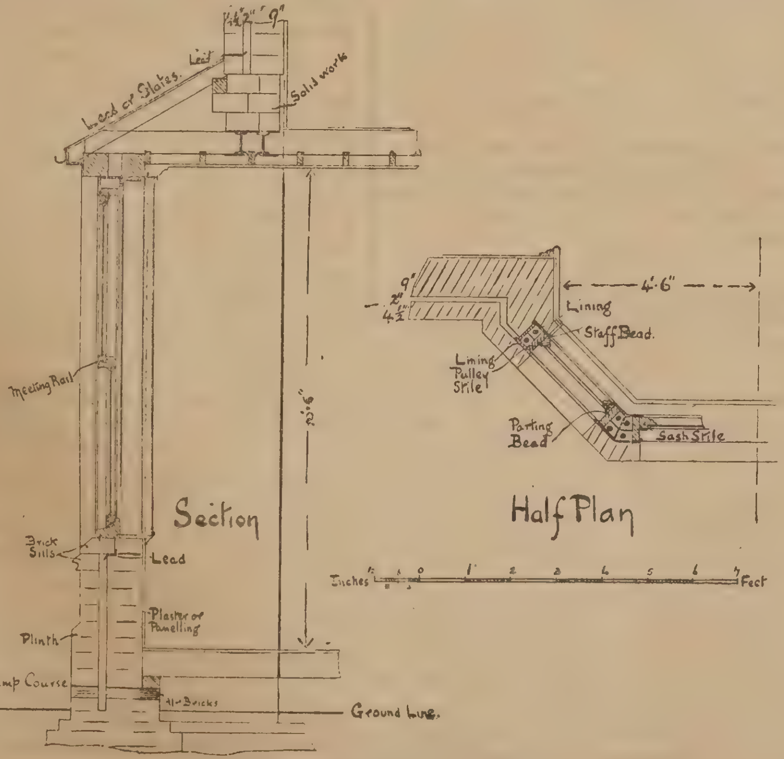
Taunton.—X. Y. Z. writes: "Kindly mention the names of makers of asbestos fire-resisting curtains and doors for theatres and public halls. Please also name a good book showing details of the construction of the stage."

The fire-curtains at Drury Lane, Covent Garden, and many other theatres are by Messrs. Merryweather, Bow Street, W.C. "Stage Construction," by Edwin O. Sachs, is the book on this subject to obtain. It is published by B. T. Batsford, 94 High Holborn, W.C.

Bay Window with Hollow Walls.

Birmingham.—J. T. C. writes: "Kindly give a plan and section of a bay window in 14in. cavity walls, with sash windows, and also the proper thickness of sash to take $\frac{1}{4}$in. plate glass, and other particulars."

It is difficult without large scale drawings to give all the details, but the general arrangement of a bay window 9ft. wide by 3ft. deep may be gathered from the accompanying sketches. The usual dimensions of the various members are somewhat as follows:—3in. (oak) sills, sun-weathered, throated and grooved. $1\frac{1}{4}$in. or $1\frac{1}{2}$in. grooved pulley stiles and heads, all tongued to 1in. grooved linings (inside and outside); $\frac{1}{2}$in. back linings; $\frac{3}{8}$in. (oak) parting beads; $\frac{5}{8}$in. × 1in. staff beads; $\frac{1}{4}$in. parting slips; 2in. brass axle pulleys; 2in. rebated and moulded sashes, with $1\frac{3}{4}$in. meeting rails, bevelled and rebated. As in this case it is proposed to use $\frac{1}{4}$in. plate glass, the thickness of the sashes may be increased to $2\frac{1}{4}$in. In order that the upper floor joists may rest on the top of the composite iron beam, and not on its lower flanges (as shown), it is very usual to fix that beam (often of 9in. × 3in. deals, bolted together) lower down, and to cover it with a wooden casing. The top of the bay in such case is usually wood panelled. G. S. M.



BAY WINDOW WITH HOLLOW WALLS.

Surveyors' Fees for Adjusting Extras and Omissions.

Leicester.—C. L. W. writes: "How are surveyors paid for adjusting extras and omissions at the completion of a building contract? Is it usual for the builder to pay—upon receiving a certificate from the architect—at the expense of the proprietor? Is his fee included in the final 'bill of adjustments'?"

Surveyors' fees for adjusting omissions and extras are charged for according to time occupied, as a rule, rather than by commission, and the account should preferably be delivered direct to the building owner, or to him through the architect. Many surveyors, however, adopt the practice of including their fee in the final "bill," when it is again included by the architect in his final certificate, and the surveyor is paid by the builder, this being perhaps the best thing to do if the builder has paid for the original quantities. The question is really one of advisability, to be determined in each case on its own merits.

G. A. T. M.

Ball-room Floor.

Hexham.—Morpeth writes: "Referring to the reply on page 104 of your issue for March 13th, is it necessary to provide for spring on a ball-room floor? I am busy with a similar job, and have specified 5in. by 2in. joists to be laid 3in. deep in 6in. of concrete, with $1\frac{1}{2}$in. pitch-pine deals in 4in. widths. Would it be better to put the joists on dwarf walls? The hall is 50ft. by 30ft. In dealing with the two floors, would it be good construction to put five rolled joists between and build a $4\frac{1}{2}$in. wall on them to divide rooms and carry floor above, using bond timber every 3ft.?"

It is generally considered desirable that a ball-room floor should have a certain amount of spring in it; a solid floor not only gives a sensation of deadness but is apt to be very cold, if not damp. The floor would probably give more satisfaction if carried on dwarf walls. The upper floors may be carried as suggested, but, instead of bond timbers in brickwork, ordinary brick-nogged partitions should be used. HENRY ADAMS.

Measuring Buildings.

London, W.C.—A. B. C. writes: "I intend to sketch and measure some old buildings, and should be glad to have some information on the subject. Are there any books dealing with it?"

Measured drawings should be done on the spot only. A large-sized sketch-book may be useful for making notes, but as the drawings will require to be made to a fairly large scale and the profiles of mouldings taken full-size separate sheets of paper are best. A useful scale for the drawings is $\frac{1}{8}$th. In order to give you a clear notion of how to proceed we will suppose you are going to measure a church consisting of nave, aisles, and chancel. First accurately plot the nave piers, then take a centre axial line right down the centre, and from certain points, marked on the floor in chalk, take cross diagonal measurements to the principal features of the side walls, such as piers, windows, &c. If possible, continue the centre axial line through the wall into the churchyard, and thus form a connecting link with the second operation of setting out the exterior. To do this, stake out a rectilinear figure outside the church, and measure the offsets to buttresses, porch, &c. The thickness of walls can, of course, only be accurately determined where a window or doorway occurs; to make an absolutely accurate plan the thickness will have to be obtained at a great many points, and it is better to do so wherever possible. If there is any stone vaulting or roof work to be planned, procure a lead pointer, and, having chalked the point, suspend it from the centre of the boss, rib, or whatever part of the roof you desire to plot, until it touches the floor of the church, when you will be able to accurately plot the chalk mark on the plan. In measuring stone vaulting it is best to thus draw out in chalk a plan of the vault above on the pavement below. The plan of the building having been prepared, the line of heights should then be drawn to the scale of the plan. As the level generally varies considerably in old buildings, a good plan is to mark a chalk line round the building with a straight-edge and spirit-level. Take measurements up and down from this line. To obtain the shape of mouldings a strip of lead about $\frac{3}{8}$in. wide should be pressed carefully into the curves and hollows; then lay the strip on a sheet of paper, and follow the shape of it with a pencil. The mouldings can be filled in to scale on the drawings afterwards. Sketches plotted to scale should not be touched again, as re-drawing destroys all their life. On measured drawings nothing should be shown that has not been measured, not even the joints of stonework; if you want to show rubble, measure a small area carefully and draw that. There is often a beauty of plan in buildings which is hidden unless surveyed and plotted; a simple and rapid method of obtaining a small-scale plan of a large building is to use scale-divided paper and pace carefully the building, adopting, supposing the squares are $\frac{1}{8}$in. square, a scale of one, two or three paces to an eighth of an inch, giving approximately 24ft., 48ft. and 72ft. to an inch respectively. In studying an old building make a point of endeavouring to find the reason for everything—study its anatomy, as it were. This will be found invaluable in designing; for if you have a reason for everything you do, your work will always be interesting. It should be remembered that old buildings belong to the racial art of architecture, having been produced by co-operative workmanship, by men who had their art handed down from their forefathers, so that the buildings are instinctively and naturally a reflex of the social condition of the people. The following books contain measured drawings: "The Abbey Square Sketch Book" (3 vols., £3 nett each), "Churches of the Nene Valley, Northamptonshire" (£2 4s.), and "The Architectural Association Sketch Book" (several volumes). These can be obtained from Mr. B. T. Batsford, of 94 High Holborn, W.C.

Instructions in Manual Training.

LITTLEHAMPTON. — HERCULES writes: "What qualifications are necessary for the position of 'Instructor in Manual Labour' in a Board school?"

Under the London School Board, instructors and assistant instructors in manual training (woodwork) are required to have passed in the first class in science subject No. 1, of the Science and Art Department (practical plane and solid geometry), and to have obtained the full "D" certificate or an equivalent thereof, namely, science subject No. 2 (machine construction and drawing), or science subject No. 3 (building construction), or a certificate in some kindred subject from the City and Guilds of London Institute. If any persons are appointed who have not these qualifications, they are required to obtain them, and are not allowed any increase of salary till they have obtained them. They must also have an adequate certificate of competency to teach woodwork; the certificate of the City and Guilds of London Institute or a certificate in Sloyd being accepted. Assistant instructors receive a salary of £80 per annum, rising by £5 annually to a maximum of £100 per annum; while instructors commence at £100 per annum and rise by £5 annually to a maximum of £155 per annum. This is for 27½ hours per week, some of which may be in the evening, though instructors may be required to teach woodwork for two additional evenings per week, being paid 4s. per evening for two hours' instruction for this extra work. No other evening work than that which is provided by the Board may be undertaken without the knowledge and consent of the School Management Committee. Assistants may be called upon to take sole charge of a manual training centre and vacancies in the number of instructors may be (but not necessarily are) filled by the promotion of assistants, if qualified and reported to be good in class management. Persons appointed may be required to attend classes for further instructing themselves at the discretion of the School Management Committee. These regulations, it should be noted, apply to London only, other School Boards having regulations differing more or less according to local circumstances and requirements. G. A. T. M.

Dividing Land into Plots.

BARNSLEY.—CHAIN writes: "The plot of land shown in the enclosed sketch (not reproduced) is to be divided up into plots of 400 sq. yds. each for allotment gardens; two 10ft. roadways also to be provided. Which is the best way to set about this? Is there any rule applicable to such a case?"

There is no rule applicable to such a case as this. The only method is to set it out by trial.

HENRY ADAMS.

Leaning's Specifications.

ILKLEY.—F. C. R. F. writes: "Can you tell me where I can get a new or secondhand copy of Leaning's 'Specifications,' published originally at 4s., but now out of print?"

We cannot tell querist where he can obtain Mr. Leaning's book on "Building Specifications" issued at 4s. and now out of print. Mr. B. T. Batsford, of 94 High Holborn, W.C., is, however, just issuing "Building Specifications," by John Leaning, price 18s. nett, a review of which is in hand and will shortly be published in our columns.

Liability to Repair House.

BEWDLEY.—C. J. W. writes: "I became the tenant of a house in 1862. Can I be called upon to repair certain cracks which have appeared? They have been caused by a sinking."

Your liability to repair depends upon the terms of your lease. But if you are a tenant from year to year you are not liable to repair the cracks if this should involve rebuilding.

A. O. H.

FIXING ELECTRIC BELLS IN HOUSES.*

BY H. E. NEALE.

AT the present time electric bells are fitted in almost every house or place of business, and the telephone is superseding the old system of speaking tubes, so that a few words about their construction and application may be of interest.

The Léclanché Cell.

The first thing that we must direct our attention to is the battery, the Léclanché form, or a modification of it, being that most used for bell and indicator work. This cell consists of a glass outer jar in which is placed an amalgamated zinc forming the positive element, the negative element consisting of a carbon plate placed inside a porous pot closely packed with a mixture of carbon and peroxide of manganese, the top of the porous pot being run in with melted pitch. The Léclanché is a single-fluid cell, the porous pot not serving to keep the fluids separate but merely to contain the broken carbon and manganese and keep it in immediate contact with the carbon plate. The exciting fluid is a solution of sal-ammoniac (chloride of ammonia). On closing a circuit the sal-ammoniac is decomposed and the chloride attacking the zinc forms chloride of zinc, which is soluble in the surrounding liquid, while the ammonia developing at the surface of the carbon forms a soluble compound with the oxygen, which it extracts from the manganese. While the cell is at work the zinc is consumed, and the chloride of zinc accumulates in the solution, the carbon remaining unaltered. The peroxide of manganese loses some of its oxygen; but after a time the supply of oxygen becomes reduced, and the hydrogen accumulates on the surface of the carbon plate, producing polarisation. Now if the circuit is broken and the cell left to rest for a time it will depolarise, the peroxide of manganese absorbing oxygen from the air.

Dry Cells.

The next cell most common in use is the dry cell. I will give a short description of an E.C.C. cell, made by the Electrical Construction Company. It consists of a carbon plate, which forms the positive pole, surrounded by manganese dioxide; outside this is a coat of lime and sal-ammoniac, and the whole is contained within a zinc case which forms the negative pole of the battery. At the bottom of the zinc case is another case of insulating material. A small piece of cotton is placed on the top of the manganese dioxide, and a piece of glass tube fixed in the top as a waste tube; the whole is run in with pitch. The advantage of the dry cell over the ordinary wet cell is that it is much cleaner, does not freeze, takes up less room, can be placed in any position, and has no solution to evaporate; it, however, has not such a long life, and the E.M.F. is not so great as in the various types of the Léclanché.

Bells.

Next we have the bell, which may be either single stroke, trembling, or continuous action. The construction is much the same in all three, with the exception of the connections.

The trembling bell is that most used. It consists of an electro-magnet firmly fixed to an iron frame and provided with a soft-iron vibrating armature, one end of which is fitted with a hammer, while the other is fixed to the iron frame by a spring having a platinum contact-piece; insulated from the frame is a contact post fitted with an adjustable platinum-pointed screw and a tightening screw.

The action of the bell is as follows:—The current entering at the terminal flows through the coils of the electro-magnets into the frame, through the spring and armature to the platinum-pointed screw, to the contact post, and thence through to the other terminal, but in flowing through the electro-magnets the current has magnetised the core, which now attracts the armature, causing it to move up against the poles and bringing the hammer against the gong; at the same time contact is broken with the contact post, and as the cores of the electro-magnets are made of soft iron they at once lose practically all their magnetism, so that the armature in obedience to the spring moves back to its former position. This action is repeated as long as the button of the push is kept in.

Of pushes there are many forms, but the principle is the same in all, the object being to join the circuit, which is kept apart by some form of spring.

Wiring.

Last, but not least, comes the wire. That used for bells should never be less than No. 20 gauge (No. 18 is preferable), and it should be tinned to prevent corrosion, insulated by at least one coat of pure rubber, and double cotton-covered and served with paraffin wax.

In wiring a building for bells it is first necessary to ascertain where they are to be fixed, the position of the pushes, and the situation of the battery.

In an ordinary house the most usual place for the bell is in the kitchen. An indicator is placed in the circuit, and shows at a glance which push has been used. There are several forms of indicators—the swinging pendulum, the mechanical replacement, and the electrical replacement. In good work all bell wires are drawn through zinc tubing to protect them from the effects of the acids in mortar and cement. While we are at this stage, mention may be made of one or two important things that a clerk of works should insist on—namely, the whole of the wire to have a coating of pure rubber underneath the cotton covering, the wires to be fixed in such places that they cannot become injured or damp, and every wire to be so fixed that it can be drawn out, and another drawn in to replace it if necessary, without disturbing the decorations or structure.

Electrical Units.

Returning to the batteries, the E.M.F. or pressure is termed voltage, the quantity of current is expressed in ampères, and the resistance through which the current passes is measured in ohms: therefore, $C=\frac{E}{R}$ which means that if we divide the resistance of the circuit in ohms into the E.M.F. in volts at which the current is supplied, the product will give the current's strength in ampères. Similarly, if we know the value of any two of the three quantities by the application of the formula, the third can at once be found, for it is obvious that the equation $C=\frac{E}{R}$ may be written $R=\frac{C}{E}$, or $E=C\times R$. Thus from Ohm's law we see that 1 ampère of current in a circuit having 1 ohm resistance requires an E.M.F of 1 volt. If we increase the E.M.F. to 2 volts without altering the resistance of the circuit we get 2 ampères. If we still further increase the E.M.F. to 4 volts we get 4 ampères of current. Similarly, if keeping the E.M.F. to 1 volt, as in the first instance, we reduce the resistance to ½ ohm, we get a current of 2 ampères, and if we still reduce the resistance to ¼ ohm we get 4 ampères.

If we wish to know what current we shall get in a circuit we proceed thus:—We first find the resistance of our circuit, which we will presume to be 4 ohms, and our batteries to produce 6 volts. Now, with the formula $C=\frac{E}{R}$ we get $C=\frac{6}{4}$; therefore, $\dfrac{4)\,6}{1\frac{1}{2}}$ ampères. Again, if we know that our current flowing is 1½ ampères, and the E.M.F. is 6 volts, what is the resistance of the circuit? Now, $R=\frac{E}{C}$, i.e., $R\ \frac{6}{1\frac{1}{2}} = \dfrac{1\frac{1}{2})\,6}{4} = 4$ ohms.

Again, we know the current and resistance, we want to find the E.M.F. or voltage: $E=C\times R$; C is $1\frac{1}{2}$; R is 4; therefore, $E=1\frac{1}{2}\times 4=6$ volts.

---

* Part of a paper read before the College of Masons on January 29th, 1901.

LONDON COUNTY COUNCIL.

THE TOTTENHAM HOUSING SCHEME.

AT last week's meeting of the London County Council the adjourned report of the Housing of the Working Classes Committee as to the Lordship Lane estate, Tottenham, for working men's dwellings came up for discussion.

Mr. Waterlow, the chairman of the committee, moved that the estimate of £91,500 be approved, and that the Council should acquire about 225 acres of land at Tottenham, Wood Green, and Edmonton, known as the Lordship Lane estate, at £400 per acre. He said that this was the largest scheme which had ever been brought before the Council, but there was no need for him to dwell on the necessity of some great proposal of the sort. They had now to consider simply whether they would buy the land or not, because all the details as to building the cottages and rents would come before the Council at a later period. The situation of the land was about as favourable as any site of the size which could be obtained. Their architect reported that he could build 5,779 cottages on the site, to accommodate approximately 42,000 persons. The scheme had been for some time before the public, and so far as he knew only three objections had been raised against it. The first was that they were interfering with private enterprise, secondly that the rents would be too high, and thirdly objections were put forward on financial grounds. As to the first objection, he had only to point to the Noel Park estate, not far from the site they proposed to purchase. That estate had been very successfully developed by the company which owned it, but in spite of that success the company had taken no steps to extend it. As to rents, they, of course, depended on the cost of building, and if the cost of building could be reduced the rents could also be reduced. They proposed several sorts of cottages at different rents, from 6s. a week to 10s. 6d., each cottage to have its own garden—so as to be able to let the houses at a rent of a little over 2s. a room. As to finance, the architect had assured them that they could not build cheaper, and if the Council could not make the scheme pay while buying at £400 per acre it would only be through mismanagement.

The Amendment.

The Hon. W. R. W. Peel, M.P., moved to add as an amendment the following words to the recommendation:—"On the clear understanding that if the Council itself proceeded to build, the cottages should be so constructed that the rent demanded should be within the reach of classes earning less than 30s. a week." He said they were bringing forward schemes for housing people who did not require such accommodation, and they were neglecting those unfortunate persons who did require housing, and whom they were turning out of their present homes by their improvement schemes. It was quite impossible for persons receiving less than 30s. a week to pay the proposed rents, and the cottages they were going to build would be taken by artisans earning good wages.

Mr. A. J. Williams, in seconding the amendment, said that in the Boundary Street area 7,500 persons were dishoused, and of these only 11 were offered accommodation at rents which they could pay. The Council had thus shown itself backward in dealing with the housing of the poor. It was said that the Council was placed under disabilities as compared with private companies, but he thought that they had better show the same persistence in getting what they wanted from the Government as they did in respect to other matters, perhaps not quite so worthy of that persistence.

Mr. Steadman, while supporting the scheme, pointed out that it would take eight or ten years to complete, and by that time the population would be increased by four hundred thousands.

Alderman Beachcroft believed that what they had to consider was whether or not this scheme was likely to solve the housing problem. He had doubts about it. Within two years they had bought great estates to accommodate 5,000 to 8,000 people, and the work on them had not yet commenced.

Mr. J. Burns, M.P., said this scheme was five times larger than the Shaftesbury estate at Battersea for labourers, and that estate paid a handsome dividend, with the annual loss of less than 1*d.* per cent. on their capital. Park Lane and Bayswater could not say that. The houses were never empty. In this scheme, as the Council did not want any dividend, they ought to do better. He did not believe in charity rents, but their proposed rents would be 50 per cent. better than on slum property in Stepney and Mile End. Until they got fair rent courts in East London this was the most important contribution to the great housing problem. The Council were "grasping the nettle."

On a division the amendment was rejected by 82 votes to 21, and the recommendation of the committee was then adopted.

Strand Improvement.

On the recommendation of the Improvement Committee it was agreed "that the working drawings, &c., and estimate of cost (£6,294) of the paving and other works in the Strand near the churches of St. Clement Danes and of St. Mary-le-Strand be referred to the works manager, with a view to the work being carried out without the intervention of a contractor, it being understood that the work around St. Clement Danes Church shall be proceeded with by night as well as by day." With reference to Carr's Restaurant, the members reported that they had been unable to approve of the first plans submitted by the owner of the restaurant, and invited him to submit an amended elevation on the basis of an English Classical design. This had been done, and they now recommended the Council to approve of the new designs. This was done.

AIR IN ROOMS WARMED BY GAS FIRES.

By THOMAS FLETCHER, F.C.S.

THE complaint as to the dryness of the air in rooms warmed by gas fires is constantly making its appearance, and, with the object of finally deciding the matter, I have been making careful experiments for some time, in such a form that they can be repeated and verified by any observer.

The hygrometer used is the ordinary Mason's pattern, a wet and dry bulb thermometer, mounted side by side; these can be obtained from any instrument dealer or chemist.

The calculation of the percentage of moisture from the difference shown by the two thermometers is not simple enough for general use, but a good rough rule sufficient for ordinary purposes, between the temperature of 45deg. and 65°, is to take the difference in degrees between the two thermometers, multiply this by six, and deduct the product from 100; the result will give the percentage of moisture, taking complete saturation as 100. This is perfectly reliable for comparative observations between the effect of gas and coal fires at the same temperatures, and exact calculations are unnecessary.

The room in which the gas fires and stoves were tested is my own bedroom, 24ft. by 16ft., with two large windows, and the days selected were dull and wet, the outside air being completely saturated with moisture. The coal fire was in a well-ventilated sitting-room of the same size.

Room Warmed by an Incandescent Gas Fire.

	Time.	Dry bulb.	Wet bulb.	Moisture.
No fire, window shut ..	11 a.m.	50°	46°	76 per cent.
No fire, window open ..	3 p.m.	50·5°	48°	85 „
Fire full on for 1½ hours, window shut	11 p.m.	56°	51°	70 „
Fire low for 8 hours ..	7 a.m.	54°	49·5°	73 „

Outside temperature, 11 a.m., 46°; 3 p.m., 46°; 11 p.m., 43°; 7 a.m., 43°.

Room Warmed by Coal Fire.

The temperatures in this room were so constantly varying from 55deg. to 65deg. that no series of correct observations was possible, but the greatest difference at any time between the wet and dry bulb, during the time the fire was burning, was 6deg., and the average 5deg., showing 70 per cent. of moisture, precisely the same as with a gas fire. Of course, in making these experiments, the thermometers must not be exposed to any direct radiant heat from the fire.

Rooms Warmed by Incandescent Gas Fire with Warm-Air Arrangement.

The fire used was the same as in the previous tests, with an air-warming arrangement added. This had 4 square feet of heating surface, the temperature of which was well below 212deg. to prevent charring the dust in the air, and consequent smell. The increase of heating power with this was 16 per cent., and the moisture in the air was not affected, a fact clearly shown by the figures. This, of course, is very small and of a low power for a warm-air arrangement, but it is as powerful as can be comfortably used in a living room where the occupants are at rest; when the outside air is comparatively dry, any dryness in the outer air is added to that produced in a warm room, and on dry days a larger air-warming and drying power would be unpleasant. In rooms where the occupants are in motion, a much more powerful air-warming arrangement can be used with comfort, and is, in fact, desirable for economical reasons.

Incandescent fire with warm-air arrangement:

	Time.	Dry bulb.	Wet bulb.	Moisture.
No fire, window shut ..	11 a.m.	48°	45°	82 per cent.
No fire, window open ..	3 p.m.	49°	46°	82 „
Fire full on for 1½ hours, window shut	11 p.m.	58°	53°	70 „
Fire low for 8 hours ..	7 a.m.	56°	51°	70 „

Outside Temperature .. 11 a.m., 47°; 3 p.m., 48°
Outside Temperature .. 11 p.m., 44°; 7 a.m., 42°.

The tests with the incandescent gas fire with warm-air arrangement could not be compared with a coal or coke fire stove, as we have none in use under similar conditions, but an attempt was made in a boiler house connected with the plant houses. This is warmed by the diffused heat from the surface of a self-contained vertical boiler, and with an external temperature of 44deg., the air being saturated with moisture, the temperature ranged from 59deg. to 60deg., and the moisture from 50 per cent. to 64 per cent. This variation in the moisture at the same temperature can be accounted for and reproduced at will, but it has no bearing on the present subject, and, therefore, need not be dealt with further.

Flueless Gas-stoves.

As these are largely used in rooms which are not properly ventilated, it is desirable that they should be included in the series of experiments. During the combustion of 30 cubic feet of gas about one pint of water is formed, and this would all be condensed on the walls and windows, but for the fact that the rise in temperature caused by the combustion increases the proportion of moisture the air will absorb without saturation, but in the absence of ventilation, when the gas is extinguished and the temperature falls, this extra moisture is condensed on the walls, windows and contents of the room, and, therefore, it is impossible to dry a room under ordinary conditions by the use of any flueless gas stove.

Tests made in a room without ventilation, 10ft. 3in. by 18ft. 6in. by 12ft. 3in. high; cubic area about 2,100ft.; gas consumption, 14 cubic ft. per hour. Area of glass in windows, 50 square feet.

Outside temperature, freezing.

	Dry bulb.	Wet bulb.	Moisture.
Before lighting ..	43·5° ..	39° ..	73 per cent.
After 1 hour ..	52° ..	47·5° ..	73 „
„ 2 hours ..	5 ° ..	57° ..	70 „
„ 3½ hours ..	60° ..	53° ..	58 „

The want of ventilation was very appreciable, the room feeling hot and close.

Repetition of the above with door open 2in. Outside temperature, 42deg.

	Dry bulb.	Wet bulb.	Moisture.
Before lighting ...	50° ..	46° ...	76 per cent.
After 1 hour ..	58° ..	53° ..	70 „
„ 2 hours ..	61° ..	55° ..	64 „
„ 3½ hours ...	65° ..	57° ..	52 „

Opening the door wide for one hour caused a drop in the temperature of 12deg. in both wet and dry bulb thermometers. In both the tests with flueless stoves the moisture condensed on the windows and walls was distinctly acid to test papers, showing the presence of sulphur in the products of combustion.

To prove that the so-called feeling of dryness caused by gas fires with flues had another source, which I have always suspected, the sheet-iron flue elbow was removed, allowing a small quantity of the products of combustion to escape into the room. The unpleasant feeling of dryness in the throat and nostrils was soon appreciable, and this is evidently caused by a trace of sulphur in the products of combustion escaping, a fact easily proved by the reddening of a strip of wet blue litmus paper, showing that the alleged fault of gas fires is caused entirely by defective flues.

The same result as regards the presence of sulphur compounds on thick damp days, or in fogs, will be found in the open air in London. Litmus paper becomes red when it touches the moisture on walls and windows, or the mud in the streets; it is acted on by the air in railway tunnels; the whole atmosphere of London in damp weather has a strong acid reaction; in fact, in November I was unable to obtain in London any blue litmus paper, although kept in corked bottles, which had not been more or less acted on by the sulphuric acid present in the air. Most of this acid is, of course, produced by the combustion of coal.

In an inhabited room, from 58 per cent. to 72 per cent. of moisture, shown by a difference of 6deg. to 8deg. between the wet and dry bulb thermometers in a room about 62deg. Fahr., will be pleasant, and this is easily obtained with either a coal or an incandescent gas fire, except when the outer air is completely saturated with moisture. A transient gleam of winter sunshine, without appreciably altering the actual temperature of a room, at once lowers the wet bulb thermometer, and by reducing the proportionate excess of free moisture, causes a pleasant feeling of warmth, although this warmth, as shown by an ordinary thermometer, has no real existence. This explains the fact that the feeling of comfort and warmth depends rather on the amount of moisture in the air than on the actual temperature as shown by a thermometer, a point to which sufficient attention has not been given in the management of sick-rooms and hospitals.

There is no doubt whatever that any room showing a temperature of 65deg. by an ordinary thermometer can be made to feel hot and close, comfortable or chilly, by variations in the conditions as regards moisture, ventilation, radiant heat, &c., and that the feelings are a much more reliable guide than a thermometer.

In the printed instructions for the use of Mason's hygrometer it is stated that an "artificial locality may be produced by very simple means, and those whose circumstances prevent them from seeking a climate suitable for their peculiar constitution can to a great extent obviate the necessity by the use of this instrument."

I trust that the very simple rule given above for reading and calculating the indications will prove of service to many invalids who are unable to select a suitable climate, and it must be borne in mind that the necessary conditions can only be produced with certainty by a gas fire with or without air-warming arrangement as required. Coal fires and stoves are much too irregular in their results to be reliable, although, where gas is not available, approximate results may be obtained with careful management. A coal fire alone will not meet all cases; a steamer to moisten the air is often used when it is already nearly saturated and the reverse effect is really required. An additional means of controlling the percentage of humidity is necessary, and this would possibly be done best by an oil stove with a flue to remove all the products of combustion, which are quite out of the question in a sick-room.

London Electric Tramway Extensions.—The new electric tramway between Hammersmith, Kew Bridge and Acton was informally opened last Wednesday. The central power station and machine shops are at Chiswick, and the hundred cars placed on the road have been made and completely equipped at these works.

Masters and Men.

The Bury Painters have Struck to the number of about 120 men. The masters have conceded an advance of wages and a reduction of hours, and the point of difference has reference to the alteration of the date of notices.

The Yarmouth Carpenters and Bricklayers have struck for an advance of wages from 7d. to 8d. per hour. The painters and plumbers had also been restless, but the former have decided to stick to their work, and an arrangement has been made with the plumbers.

The Carpenters and Joiners in Dudley and District have struck work in consequence of the employers calling upon them to submit to a reduction in wages of from 8$\frac{1}{2}$*d.* to 8*d.* an hour. The employers state they are compelled to enforce the reduction owing to the depressed state of trade.

The Perth Joiners have Struck Work.—Some months ago the masters intimated that they intended to reduce the wages from 8$\frac{1}{2}$d. to 7$\frac{1}{2}$d. per hour. The men wrote that they could not agree to the reduction, but no notice was taken of their reply till the end of last week, when a number of employers offered 8d. an hour. Seven masters have agreed to go on at the old rate of wages, but the men employed by the six firms who insisted on the reduction have struck. About 70 men are out.

The Irish Building Trade Dispute.—Owing to the extension of the Belfast building trade dispute to Dublin and the operations of the Employers' Association in the Irish metropolis, the Belfast executive of the Amalgamated Carpenters' and Joiners' Association threaten to bring out every man belonging to their trade union in both cities. The Belfast secretary states that the strikers are receiving most satisfactory financial support, not only from the headquarters in Manchester, but from other trade societies, and there is still a fund of £270,000 to fall back upon.

The Coventry Building Trade Dispute has been settled. Mr. A. A. Hudson, barrister-at-law, who was appointed by the Board of Trade to act in the building trade dispute at Coventry between employers and operatives, sat last week. Notice had been given by the Master Builders' Association of a reduction of $\frac{3}{4}$d. per hour for bricklayers (from 8$\frac{3}{4}$d.), painters by $\frac{1}{2}$d. (from 8d.), and labourers by $\frac{1}{2}$d. (from 6d.), and shorter hours during the two midwinter months. The employers' contention was that present rates of pay were based on a period of activity in business which has been unknown for four years past, and that this fact, coupled with the general trade conditions of the country, justified the proposed reductions. The carpenters, joiners, plumbers, and painters agreed to arbitrate, but not the bricklayers and labourers, who were consequently locked out. Mr. Hudson found that the notice given was bad, being delivered a day too late, and therefore the existing rules would stand.

Law Cases.

A Difference about the Cost of 133 Houses.—At the Birmingham Assizes in August last an action was tried by Mr. Justice Wills, in which George Crouch, builder, of Hockley, sought to recover from William Roberts, estate agent, the cost of 133 houses erected by the plaintiff at Selly Oak. The jury found for the plaintiff, and the case was referred to arbitration so that the cost might be ascertained. Mr. L. Morton Brown, barrister, was appointed the referee, and he held several sittings in Birmingham. Messrs. Arnold Harris and G. Kenwrick, surveyors, called by the plaintiff, estimated the cost of the houses at £24,642, whilst the defendant's surveyors, Messrs. A. Edward and S. J. Holliday, estimated the cost at £14,228. The referee has now given his award, allowing £20,575 9s. as the cost of the houses. To that sum is added £1,125 awarded for profit, &c., and after crediting payments already made, &c., there remains a balance due to the plaintiff of £6,231 9s.

Keystones.

Bristol Police Courts Competition.—Mr. Henry Williams has won the first premium of £100 for designs for the extension of the Bristol Police Courts. The competitive plans—17 in number—were sent in early in February. The Finance Committee selected five for consideration. The second premium of £50 goes to Messrs. Buckland and Farmer, of Birmingham; and the three other selected designs were by Messrs. Holbrow and Sons, Mr. E. C. Hanson, and Messrs. La Trobe and Weston—all of Bristol. The successful plan provides for two new courts—one a large room.

At Brixton Congregational Church a new chancel has been built as a memorial to Sir Henry Tate, the founder of the National Gallery of British Art and of many Free Libraries in South London. The chancel is in the form of a large bay, and takes the place of a small structure which formerly was occupied by the organ. The style is described as Classic. Leading features of the new work, for which Mr. P. Morley Horder was architect, are a handsome pulpit, rood screen, organ lofts—one at each side—and rich wood panelling round the lower part of the wall. Five lancet windows of stained glass are the only parts of the old chancel which have been put into the new one.

A new Infectious Hospital at Chickenley Wood, Dewsbury, is being erected. The scheme comprises an administrative block containing two drawing, dining, and doctor's apartments, dispensary, bedrooms, two bath-rooms, lavatories, and store rooms. Two fever pavilions, each 150ft. by 30ft., are being provided, and one has already been roofed. The other is not so far advanced. There will be accommodation in each for twenty-two beds, with a nurses' room in the centre, cutting off the male from the female wards, and to each pavilion is being added a separate ward for special cases. An isolation block for four beds, with laundry, wash-house, lodge, and offices will be constructed later. Accommodation is being provided for forty-eight beds, and the newest appliances as regards ventilation, steam-heating and electric lighting will be adopted. It is proposed to treat scarlet fever, typhoid fever, and diphtheria. The contractors are Mr. John Pickersgill, Ossett, mason; Messrs. A. and S. Wheater, Leeds, for the concreting and plastering; Mr. George Hargreaves, slater; Mr. Frank Newsome, plumber; Messrs. E. Chadwick and Sons, joiners; Mr. F. Firth, ironwork; Messrs. C. Kite and Co., London, ventilators. Mr. G. A. Fox is the architect.

New Business Premises at Newcastle.—The "Kingo Works" of Messrs. Davison and Pickering, Limited, 13 to 17 Stowell Street, Newcastle, have recently been opened. The site covers an area of over 800 sq. yds. The block of warehouses has a main frontage to Stowell Street being 72ft., and rises to a height of about 80ft. above the street. The buildings are of brick, with stone dressings and Accrington red-brick facings; there are seven floors with a total floor area of fully half an acre. The building is in two departments, being divided vertically by a division wall, with communication on each floor, one side being for provisions, and the other for groceries. Each side is served by an electric lift running up the full height from basement to roof. All the machines used in the business are fitted with electric motors, and the lighting is by electricity throughout. There are entrance cartways on each side of the building, and six loading and unloading platforms, the openings to which are closed with steel revolving shutters when not in use. The private office and saleroom are on the ground-floor, the other offices being on the first floor. The buildings are heated with steam-pipes and radiators, and hot water is supplied all over the building where required. Messrs. Badenoch and Bruce were the architects; Mr. Alexander Bruce was the general contractor. The electric lifts are by Messrs. Waygood and Co., London, and the electric lighting and motors for machines, &c., are by Messrs. Thomas G. Usher and Co., Eldon Square. Messrs. Henry Walker and Son, Limited, have fitted up the steam-heating, hot-water supply, and bacon-drying arrangements.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.		WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDERS MAY BE OBTAINED
		BUILDING.		
April	12	Ebbw Vale, Mon—Houses	Pretoria and Bloemfontein Building Clubs	J. P. Davies, Eureka Place, Ebbw Vale.
"	12	Hoylake, Cheshire—Lavatories, &c.	Urban District Council	T. Foster, Engineer, District Council Offices, Hoylake.

TENDERS.

Information from accredited sources should be sent to "The Editor." Results of tenders cannot be accepted unless they contain the name of the Architect or Surveyor for the Work.

BEDFORD.—For the erection of a new shop front, Tavistock Street. Mr. Harvey Sale, architect, Bedford:—

R. Black	£96 15	T. Coleman	£92 0
Cooke & Parrott	96 0	C. Negus*	89 10

* Accepted.

BEDFORD.—For alterations to premises, 169 Tavistock Street, for Mr. Walter Grant. Mr. Harvey Sale, architect, Bedford:—

Rootham	£209	T. Coleman	£193
C. Negus	204	James Ebden*	168
Cooke & Parrott	193		

* Accepted.

BEDFORD.—Accepted for the erection of a new shop front, St. Peter's Street, for Mr. Whitbread, of the "Old George Inn," Bedford. Mr. Harvey Sale, architect, Bedford:—

Cooke & Parrott	£195

BITTERNE, Hants.—For the drainage of Bitterne, for the South Stoneham Rural District Council:—

Nicol & Duke	£6,228	H. Plascott & Son	£5,998
F. Osman	6,003	S. Saunders,* London	5,837

* Accepted. [Engineer's estimate, £6,790 10s. 9d.]

BLACKHILL, Durham.—For the extension of cemetery at Blackhill (fence walls, drainage, road-making, &c.), for the Benfieldside, Consett, and Knitsley Joint Burial Committee. Mr. Geo. Thos. Wilson, architect, 121 Durham Road, Blackhill:—

E. Taylor, Durham	£1,670 2 0
J. Allison, Rosemount, Consett	1,310 0 0
J. Eltringham,* Railway Terrace, Blackhill	1,300 0 0

* Accepted.

BLYTH, Northumberland.—For the erection of new premises in 5 Bridge Street, Blyth. Mr. J. Goulding, jun., architect, Blyth:—

R. Baxter, Blyth	£3,052 0 0
J. & W. Simpson, Cowpen Colliery, Blyth	2,925 14 6
Barron & Temple,* Cowpen Quay, Blyth	2,881 17 7

* Accepted.

CHINGFORD.—For the erection of a new factory at Hale End. Messrs. Searle & Hayes, architects:—

Maxwell Bros, Limited	£1,824	A. Barton	£1,509
Lascelles & Co.	1,716	Dobson	1,438
W. Shurmur	1,548		

FRINTON-ON-SEA, Essex.—For making up and sewering portions of Second Avenue, Third Avenue, Ashlyns Road and Holland Road, Frinton-on-Sea, for Mr. R. Powell Cooper. Messrs. Homer & Co., surveyors, Estate Office, Frinton:—

Pedrette & Co.	£10,671 13 10	F. W. Anderson	£6,915 0 0
Dupont & Co.	7,514 0 0	H. J. Linzell	6,638 9 0
J. E. Trueman	7,415 0 0	Mackenzie & Sons*	6,106 12 8
E. West	7,370 0 0	Burgoyne & Sons*	5,971 14 7
Moran & Sons	6,987 17 8		
R. Moore	6,962 11 7		

* The contracts were divided between Mackenzie & Sons and Burgoyne & Sons.

GLOUCESTER.—For the erection of new buildings in connection with new buildings for refuse destruction, for the Corporation. Mr. Harry A. Dancey, architect, 26 Clarence Street, Gloucester:—

A. & E. King	£4,960 0 0	T. J. Williams	4,096 0 0
J. Gurney & Sons	4,731 19 1	W. Bowers & Sons,* Hereford	4,027 0 0
W. Jones	4,560 0 0		
W. Byard	4,305 0 0		

* Accepted.

[Rest of Gloucester.]

LONDON.—For proposed rebuilding of 39, 40 and 43 Trinity Square, for the Executors of the late Mr. C. J. Knowles, from drawings prepared by Mr. C. Watkins, of Glebe House, Sherborne Lane, E.C., exclusive of fixtures and fittings. Quantities by Mr. Deacon:—

Lascelles & Co.	£27,300	H. Lovatt	£26,250
Patman & Fothering-ham	27,280	Colls & Son	25,860
Ashby & Horner	26,987	Foster & Dicksee	25,716
F. & H. F. Higgs	26,938	W. Downs	25,434
		Greenwood	25,374

LONDON.—For the erection of a new storey over ante-room, &c., in order to provide a new drawing office for Architect's Department at the head offices, for the London School Board. Mr. T. J. Bailey, architect:—

E. Triggs	£2.960	E. Lawrance & Sons	£2,478
Lathey Bros.	2,949	J. Garrett & Son	2,414
Holloway Bros.	2,720	T. L. Green	2,187
H. Wall & Co.	2,680	Stevens Bros.	2.060
F. & H. F. Higgs	2,644	E. P. Bulled & Co.*	1,945
F. G. Minter	2,638		

* Recommended for acceptance.

LONDON.—For improvements at Edinburgh Road School, for the London School Board. Mr. T. J. Bailey, architect:—

W. King & Son	£9,517 0 0	O. Craske	£8,848 0 0
J. Simpson & Son	9,280 0 0	Leslie & Co., Ltd.	8,814 7 2
J. & M. Patrick	9,051 0 0	Patman & Fotheringham, Ltd.	8,473 0 0
Treasure & Son	8,953 0 0	J. Garrett & Son*	7,984 0 0
Martin, Wells & Co.	8,904 0 0		
W. H. Lorden & Son	8,852 0 0		

* Recommended for acceptance.

LONDON, E.—For the erection of stable buildings, Richardson Street, Whitechapel, E., for Mr. E. Rochester. Mr. Ernest H. Abbott, architect, 6 Warwick Court, Gray's Inn. W.C. Quantities by Mr. Alfred Johnson, 34 Imperial Buildings, Ludgate Circus, E.C.:—

A. Webb	£6,379	A. E. Symes	£5,640
W. Harper	6,028	R. & E. Evans	5,550
W. Walker	5,668	G. Maddison	5,499

LONDON, N.E.—For the erection of gymnasium at Mare Street, Hackney. Mr. F. S. Hammond, architect:—

W. Shurmur	£2,394	S. J. Scott	£2,381
Larke & Son	2,384		

LONDON.—For the erection of special school, Daniel Street, for the London School Board. Mr. T. J. Bailey, architect:—

J. Chessum & Sons	£3,957 18 2	G. S. S. Williams & Son	£3,556 0 0
Treasure & Son	3,738 0 0	E. Lawrance & Sons	3,537 0 0
Clarke & Bracey	3,711 0 0	Patman & Fotheringham, Ltd.	3,387 0 0
Leslie & Co., Ltd.	3,626 6 1	Willmott & Sons, Hitchin*	3,352 0 0
H Wall & Co.	3,621 0 0		
J. Grover & Son	3,595 0 0		
W. McCormick & Sons	3,585 0 0		
C. Cox	3,556 0 0		

* Recommended for acceptance.

LONDON, N.—For the erection of printing works, Tottenham, for Messrs. J. M. Kronheim & Co. Mr. Ernest H. Abbott, 6 Warwick Court, Gray's Inn, W.C., architect. Quantities by Mr. Alfred Johnson, 34 Imperial Buildings, Ludgate Circus, E.C.:—

Griffiths & Co., Ltd.	£5,215	Wells & Son	£4,775

LONDON, N.E.—For alterations, &c., at 204 and 206 Lower Clapton Road. Mr. J. H. Bethell, architect:—

Lidstone & Son	£2,185	Limes	£1,905
G. Sharpe	2,100	Gerard	1,885
Silk & Son	1,990	Robey	1,800
W. Shurmur	1,980	Snewin Bros. & Co.	1,674

LONDON, S.W.—For the erection of a house, Aldrington Road, Streatham. Mr. William H. Burt, architect, 10 Bush Lane, E.C.:—

Smith & Sons	£3,837 0	Lorden & Sons	£2,719 15
Courtney & Fairbairn	2,939 0	Bulled & Co.*	2,689 0
G. P. & H. Barnes	2,756 0		
Patman & Fothering-ham	2,754 0		

* Accepted.

PETERBOROUGH.—For the erection of shops, &c., in Cowgate and King Street, for Mr. C. F. Thomson. Mr. J. G. Stallebrass, architect, North Street, Peterborough:—

Shops.

Thurley Bros.	£4,880 0 0	J. Lucas	£3,598 0 0
J. Woolston	4,340 0 0	J. Cracknell	3,564 0 0
R. Shanks	4,150 0 0	R. J. Nichols	3,558 14 0
C. F. Colls	3,998 0 0	F. H. Nichols	3,527 13 0
Bridgfoot & Son	3,922 18 1	D. Gray	3,431 9 0
J. Guttridge	3,779 0 0	H. Watson,* Peterborough	2,997 0 0
Hipwell & Co.	3,600 0 0		

* Accepted.

SALTASH.—For alterations and additions to No. 2 Port View Villas, for Mr. J. Bennett. Mr. Edgar M. Leest, architect, Saltash and Devonport:—

S. E. D. Ough	£274 10	W. V. Alford	£260 0
W. H. Rothery	264 0	Taylor & Mutton*	245 0

[All of Saltash.] * Accepted.

TOTNES, Devon.—For the erection of Wesleyan church and schools, Fore Street, Totnes, for the Trustees. Messrs. Bridgman, A.R.I.B.A., and Bridgman, M.S.A., architects and surveyors, Bank Chambers, Torquay and Paignton. Quantities by Mr. V. C. Brown:—

W. A. Goss, Torquay	£2,100 0 0
R. F. Yeo, Torquay	2.062 12 0
Arscott & Son, Buckfastleigh	1,941 0 0
T. Brown, Torquay	1,888 0 0
J. C. & W. Watson, Torquay	1,880 0 0
T. Brooks, Totnes	1,727 18 0
Reeves & Son,* Totnes	1,711 0 0

* Accepted.

An Architectural Causerie.

Queen Victoria Memorial.

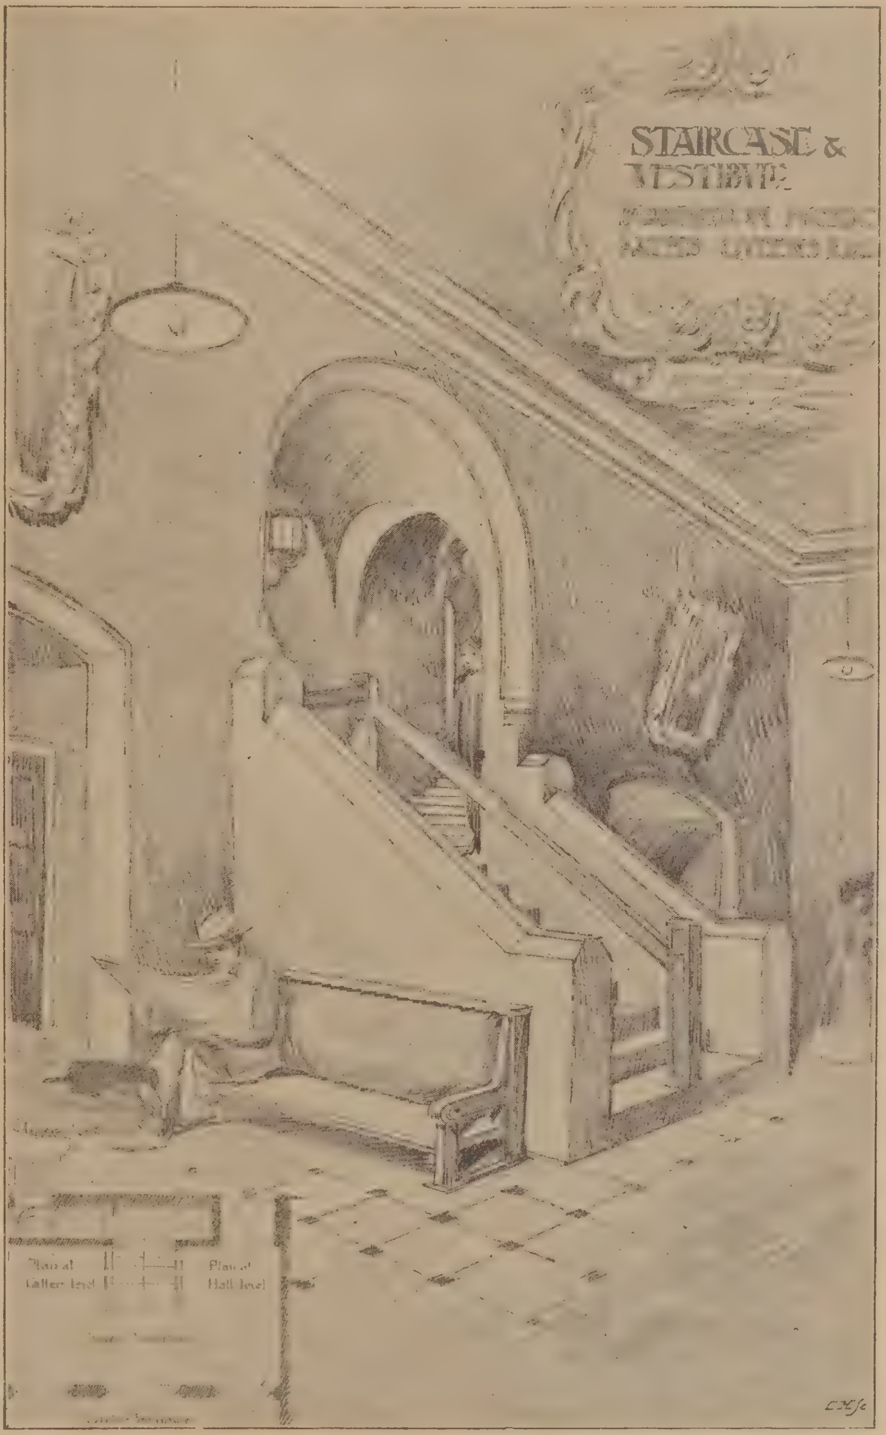
A lively criticism is proceeding in the daily press respecting the Queen Victorial Memorial; we give the gist of it on another page. From this it will be seen how the decision of the Executive Committee is censured by leading architects, sculptors, and designers. We need not reiterate these opinions here, for in this column we have already expressed ourselves—among the very first—on the unwise selection of one sculptor and five architects for the Memorial. There are rumours that the committee will reconsider their proposals, in view of the loud outcry which is being made against them. We hardly think, however, that they will change anything for the present. The selected architects will send in their designs to the Office of Works by the end of June. After that we may expect changes and reconsiderations, but hardly before.

The Balcony and "Loggia."

There is perhaps nothing which so strikes an Englishman upon his first visit to Paris as the profusion of balconies, the more so, indeed, from their rare and declining use in his own country. There is one to nearly every window, and the straight lofty streets seem to his unaccustomed eyes like a vast bird-cage, for these projections are all of iron; they are light, strong, generally of simple design, sometimes more elaborate, and occasionally enriched with ornamental brasswork or gilding. The windows are one and all casements—in the larger rooms they open to the floor; outside each is a pair of *jalousies* or wooden sun-blinds on hinges; the entire city is of light-grey stone, inclining to cream colour. From the point of view of architectural effect, the immense straight streets are grand, but after a time they become slightly monotonous; what relieves them is the balcony. It speaks well for the taste of Parisians that the variety of design in balconies is so great; some slight difference can always be observed at each storey, and between one block of buildings and its neighbour.

Other northern capitals and provincial cities, though making much use of the balcony, do not employ it so profusely as Paris; in all, however, it is a recognised building adjunct, and a popular architectural feature. In the South of Europe it is in general use; Charles Dickens said that in Italy it "rained balconies." They are generally of stone, but the effect is less graceful than in France. The balcony is looked upon as a necessary extension of the room in a hot country, and is provided with seats, and coloured cushions over the balustrade to lean the arm upon; little orange trees in tubs are often placed within it, and enliven the street with their green leaves and golden fruit.

Less frequent in use, but always effective, is the loggia, or open recessed gallery; it is practically an opening in the front, usually in the second storey from the ground, columns, and sometimes arches, taking the place of wall; it thus creates a fine covered gallery, which differs from a balcony in not projecting beyond the face of the building; the columns appear as lines of light against a hollow background of shade. Another form of loggia is found in the numerous *campanile* or bell-towers of Italian cities; near the summit a post for a watchman in time of war was required, and a ring of columns and open arches was introduced, enabling a warder to survey the surrounding country; these are still sometimes used as look-outs for fire.



DRAWN BY E. A. RICKARDS.

Above the loggia the tower is usually continued upwards in some graceful form, and occasionally, as in the tower of St. Mark at Venice, terminates in a stone pyramid or steeple.

In England the balcony has never been very popular. The Palladian houses of the last century which make up the greater part of central London have shallow balconies to the drawing-room floors, but they are little used and of questionable safety; the vast stucco regions built in the present century, extending southward from Hyde Park Corner and westward from the Marble Arch, exhibit the balcony also, but it is of one uniform design as far as the eye can reach, a paltry feature. The balcony counts for little in the most recent designs, although it might be of some use in case of fire in the lofty structures now being built. In the suburbs there is a species of balcony not infrequently seen which is intensely ridiculous; it is so constructed that no one can enter it; it is impossible even to utilise it for displaying flowers. Of the loggia two fine examples have recently been given to London in the new Her Majesty's Theatre and the Carlton Hotel; they are eminently appropriate to a Palladian building.

SOME THOUGHTS ON PLANNING.*

By ARTHUR T. BOLTON.

THE Art and Science of Planning is a subject so extensive in its scope, and of such vital importance to us as students of architecture, that I have specially asked to be allowed to reduce the title of my paper to that of "Some Thoughts on Planning," so as to give a right impression that I am attempting nothing more than some of those thoughts on this subject which occur to us in our daily work.

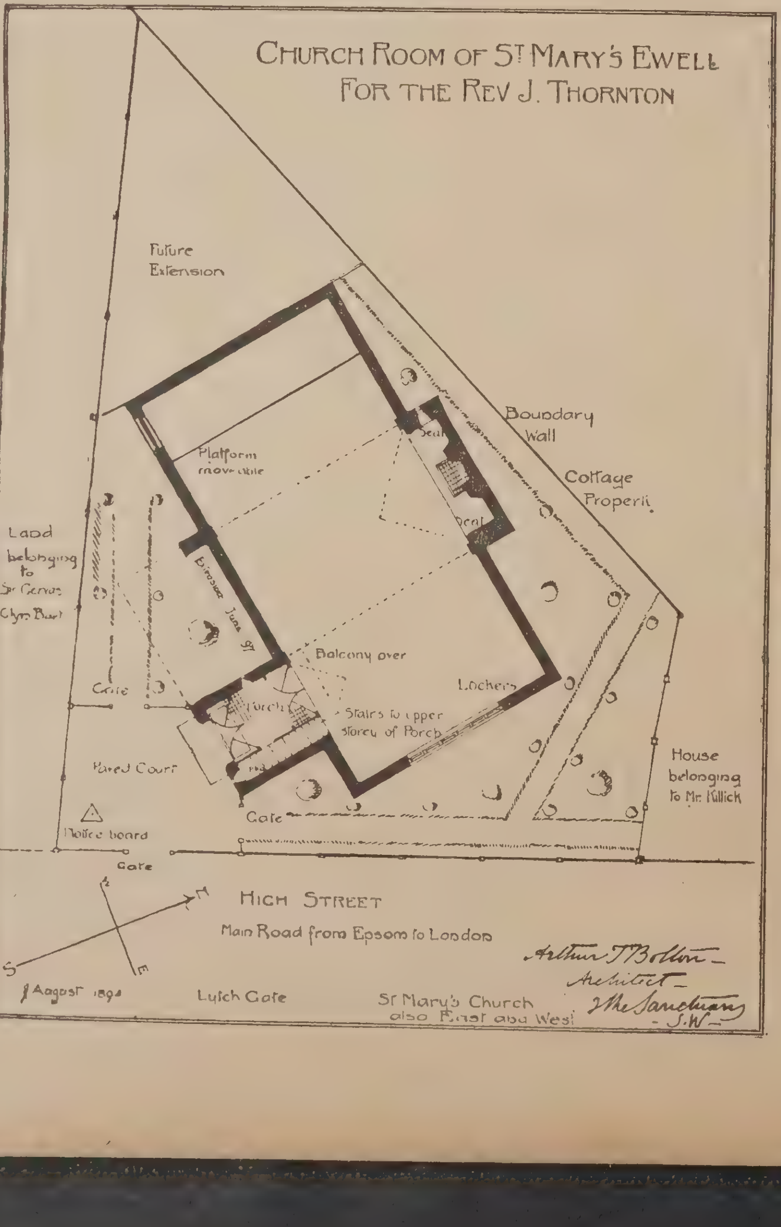
Looking back, if I may venture to allude to personal experiences, I feel that as a student some of the points which I hope to make clear to you would have been of the greatest assistance to me had I been able to grasp their significance at the time. The help that an older student can offer to a younger is that of shortening the road by which he will have to travel, by suggesting some of the principles and methods that, in his experience, govern the majority of cases. This enables the student to avoid those circuitous methods of reaching his goal which swallow up so much precious time and energy. I trust that some such assistance may be derived by some of you from the reading of this paper.

I heard a student whose plan had been somewhat severely criticised say he supposed planning could be acquired like everything else; while the question is often asked, Can planning be taught? Personally, I think it should be put the other way, as, How can I learn, or how can I teach, the art and science of planning?

First of all, then, as to the importance of planning, in regard to which I shall only quote a characteristic and conclusively brief sentence of an architect, one whose achievements have exerted a great influence on modern architecture—"I love plans." Gentlemen, I do not for a moment suppose that, knowing the keen life and the active practice characteristic of Birmingham, I can tell you anything on many sides of this question of planning that you do not know much better yourselves. In fact, I desire rather to apologise for attempting such a subject; but circumstances have lately led me to think that some such thoughts as I have put together would really be of service to the younger students. Besides, I desire to plead for a greater recognition of the artistic aspect of planning, and to urge that all is not done when a clever adjustment of the requirements of the case has been found to be workable, but that a good plan is one which by good internal and external elevations reveals itself as fine architecture.

CHURCH ROOM OF ST. MARY'S EWELL.

The first point for the student, then, shall be this—learn to plan by learning first to get up your subject. Well do I know that easy and fatal path that leads to useless schemes, the idea that the conditions given to you have only to be shaken and turned inside out, twisted together, and made into a plan. It is so much trouble, and often involves expense, to go and see similar buildings, to look up modern examples, to consult managers and worry experienced friends, as well as to collect a thousand-and-one trivialities of detail, not to mention the fallacious thought at the back of your mind that the result will be so much more original, and there will be no cribbing, if you do it all off your own bat.



Consequently, as "nothing out of nothing comes," your costly and laborious set of drawings will not be looked at by any judge, because, however ingenious certain parts may be, he will recognise at a glance that they are only elaborations of a scheme based in some essential on a wrong principle.

Besides one's own little affairs of this kind, this year's Soane is a striking instance of what I mean. The subject, "a club in a large city," was a particularly good one, and drew an exceptional response in the point of the number of the competitors, but no award of the prize has rightly been made, because there was not a single satisfactory scheme. One of the judges is reported as saying "he did not suppose anyone of the competitors had ever been inside a first-class club in his life"—a pithy and polite way of putting the point.

A good architect must have the barrister's power of getting up a case. If clients only knew it, such ability may be a much better recommendation in an architect than the fact of having built a similar building before. You cannot start too early on such lines. Suppose you have as a class design a shop or a doctor's house, a hospital, or what not; live for the time with the one idea, first, of what, say, a shop is, and afterwards of what it ought to be; look up shop plans, visit shops, worry shopkeepers with the why and the wherefore. Ask an agent why those shops of his do not let. Enquire of your lady friends their favourite shop, bore everybody with shops till you have the facts at your finger's end, and then you will give us the shop as it ought to be with some chance of success.

Secondly, in this pursuit of knowledge, be exact. Measure, do not sketch, plans; or if you put dimensions on to notes of plans, let it be so that the said plan will draw out to scale. Experience acquired in plotting plans will save you much time in planning schemes in the rough, as you will instinctively avoid errors and impossibilities of scale. Remember that 6 in., say, in the width of dining-room, will make the difference between what will just do and a failure. Put to every dimension you have not taken exactly a (c), as this practice will lead you to avoid guesses, especially after a plan or two has failed to work out in the plotting out on paper.

An old foreman taught me a lesson in that connection. When I said some dimension was about my height, he said: "Ah, that was like the apprentice who was sent from the shop to the job to measure an opening, and returned through the streets calling out to the people to make way, as his outstretched arms gave the width of a door."

Similarly you should endeavour to have at instant command the sizes of all ordinary parts of a building, common fittings, and furniture. Few things are more deceptive. For instance, how rarely one has the courage to draw a counter 3ft. wide; it looks so enormous on an ⅛th scale plan, and many a disagreeable experience has awaited the architect in consequence of shirking the inevitable in the shape of the actual fitting-up and furnishing of his plan. Service and other unattractive parts of the plan are frequently cramped in the same way for the sake of the grand rooms, in which, however, hereafter you will see unsightly encroachments rendered necessary by such want of prevision.

In this pursuit of knowledge it is a great mistake to ignore the officials and domestics who will have the working of the building. A good architect would, if he had the option, consult everyone, however humble his position, on that part of the building which came within his own particular sphere. A curious instance on this point was related to me of a very eminent architect by a friend of the client in question—all parties being now deceased. It was a case of a house alteration where, as the kitchen was at a great distance, a corridor to the dining-room had to be built, and the butler stipulated for a width ample to allow two men with full trays to pass each other. On the client representing this to his architect he was told to leave everything to him and all would be well; the butler, however, while the corridor was building, protested that it was too narrow, but without effect so far as the architect was concerned; on completion, however, the failure was evident to all, and great expense had to be incurred in correcting the mistake. Cases like this are to be avoided at all costs, as few things

MEZZANINE FLOOR.

contribute more to bring discredit upon our profession. Such cases form, I fancy, the basis of the legend of the forgotten staircase so generally cast in our teeth.

As a counterpart, take the example of John Dobson, of Newcastle, who spent a whole day on a railway platform studying the traffic before he hit on the idea of a circular sweep to the station as the best solution of the problem.

Such study pushed to extremes leads to highly specialised planning, as to which I have considerable doubts. It appears to me that, particularly in such cases as municipal offices, &c., it will often prove a failure, as by reorganisation and change of character, reductions or extensions of staff, &c., the original basis of the scheme will be so upset that the special points of the plan will be quite lost. I have observed in Continental public plans that one is often unable to determine the particular work to be carried on in the building. You have a kind of official disposition convenient and easily available for any kind of office work, so that I fancy it is possible to over-specialise in such matters. In house planning over-specialisation, showing itself in a neglect of the average requirements of people, may involve a serious loss to a client's family, if not to himself, owing to the house being either unsaleable, or only to be disposed of at a sacrifice. It may become your duty in the case of a client with fads to point out the risk of such a contingency.

Regarding Receipts and Tricks in Planning.

I have for the former no hints to give you; in fact, I do not believe in either. No two cases will ever really be quite on the same footing; and while types of plan are to be recognised and studied most carefully, ready-made solutions are to be regarded with the utmost suspicion. For the latter they never succeed in more than at the most a first impression, and are a nuisance ever after. Good planning is essentially simple and straightforward; it requires no explanation when the requirements are known, and it appears so obvious that it excites no remark. It is quite too easy to those who do not know. Bad planning you cannot follow; it has to be explained, not to say excused. It is incoherent, and has no definite aim. It is wrong in scale, wasteful and yet cramped, costly to construct, and incapable of any adaptation or extension.

Some good judges maintain that there is always a "best plan," if not "the only plan," in each case, and that the student must exhaust every possible combination in order to satisfy himself that he has the true solution. It certainly is a duty to satisfy yourself that there is no alternative to the plan you have adopted. I think, however, that with experience you will quickly be able to run over the various possibilities, because, as a rule, what appear to be alternatives are only a snare.

Having observed the evil results to students of over-much change in their ideas, I believe that it is best to be rather slow to start your scheme on paper. A student who has well turned over his idea in his mind before roughing it out on paper will often find that such a first sketch, however many alternatives he may afterwards very properly attempt, remains after all the true solution. It is recorded that Barry noted on the back of an old envelope the idea of the masterly plan of the Houses of Parliament, from the main lines of which, for all his subsequent alterations and improvements, he never departed. I have often admired the clear-headed way in

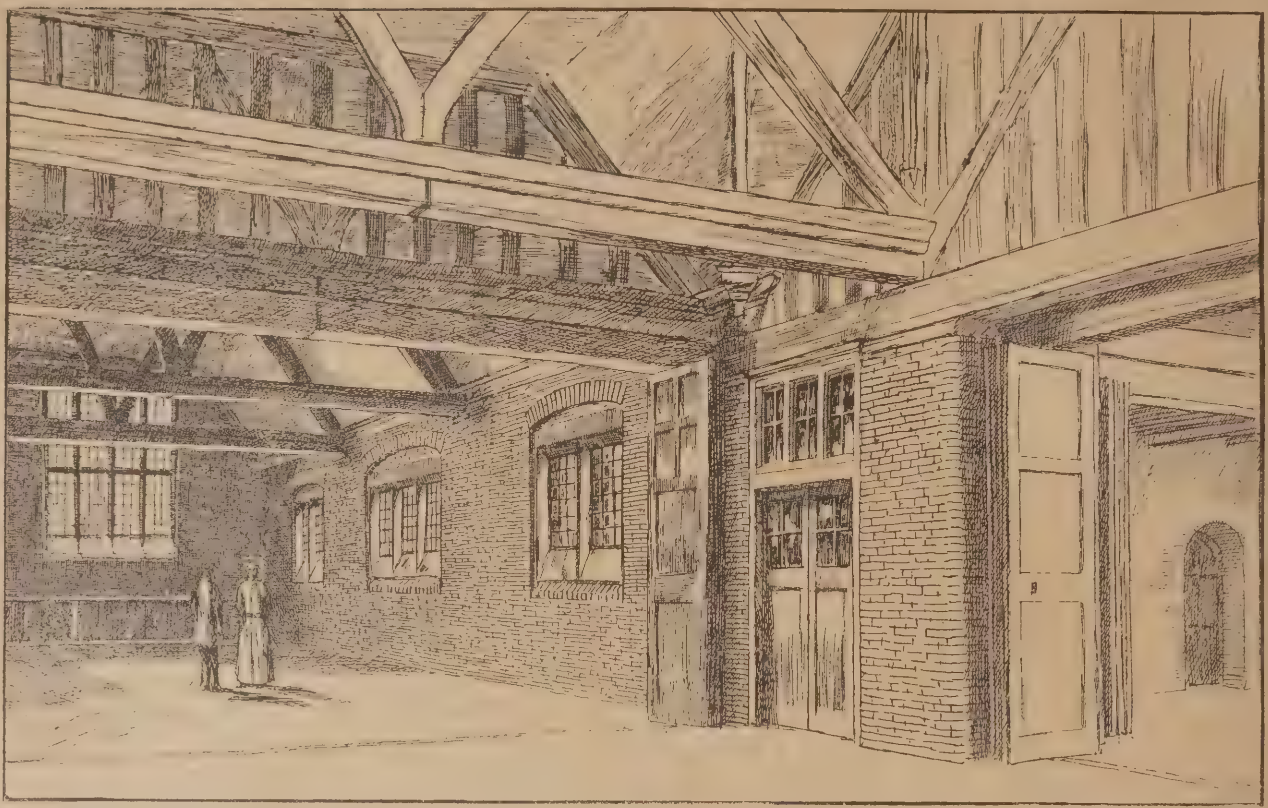
PLANS OF ST. STEPHEN'S NATIONAL SCHOOLS, PADDINGTON. ARTHUR T. BOLTON, ARCHITECT.



ST. STEPHEN'S NATIONAL SCHOOLS, PADDINGTON: IN THE NEW BOYS' SCHOOLROOM, LOOKING SOUTH. DRAWN BY F. L. B. GRIGGS.
ARTHUR T. BOLTON, ARCHITECT.

which some students will, after an apparently casual examination of a series of designs, tell you in a few words the main idea of each. As old soldiers give their battles after dinner, so schemes are often originated and described by a diagram in cutlery. In time you will probably come to distrust a scheme that requires the production of many sheets of drawings and interminable *viva voce* explanations.

Such selective power arises from a recognition, possibly unconscious, of types in plan. It can be acquired, I think, by a deliberate study of the evolution and development exhibited in a successive series of plans. Every student should, for the purpose of comparative study of type, pursue one or more branches of this subject, as, for instance, the growth of the church plan of to-day from the early times; the development of the house plan in this country as compared with that of, say, France or Italy; the origin and progress of elementary school planning; or even the ceaseless problem of the jerry-builder's house at an absolutely knock-out price.

A word must now be said as to the financial aspect of this part of our work. A mistake in planning may be a very costly affair—houses that will not let, or only at a reduced rental; offices depreciated by the entrance being in the wrong street; hotels that are costly to staff and maintain; these are a few only of the instances that might be given under this head. Often your plans may be the basis of a financial scheme; that is to say, a given sum being provided, you have to arrange for a fixed return upon the money in the shape of the annual interest and proportionate repayment of capital. In a case of this kind you will be wise to consult with an experienced surveyor, but I would urge upon you the importance of grasping the points at issue yourself as well, and of bringing within your philosophy of art, whatever it may be, some conception of architecture as the outcome of conditions more often than not prescribed by tendencies beyond any individual control. Complying with the social and other circumstances of your own time, carry on the great traditions of historic architecture.

It would obviously take up too much space to go fully into the question of common errors, and of the ordinary causes of failures in plan, against which you have to be on your guard; but I hope it may be useful to suggest a few heads under one branch—that of house planning. Avoid, therefore, the following bad qualities:—

1. House plans in public work, and *vice versa*.
2. Excessive smallness in size, and the reverse.
3. Disproportion of the various services.
4. Expense in maintenance and in staffing.
5. Absence of privacy.
6. Extreme compactness, resulting in noise.
7. Dangerous and difficult complexities.
8. Bad levels and wrong aspects.
9. Draughts and bad lighting.

A similar table may be made for each group of plans, though of course many of the points will recur in each, with simply another shade of meaning.

Certain common traps and pitfalls may be indicated, as the two-storeyed hall containing a staircase with gallery at the first-floor level, which is a favourite amateur receipt, whatever the size of the house. I imagine everyone starts by a try at that idea. A variation of the same is a grand square hall, vaulted all ways on to a central pillar, the scale being probably about 4ft. to 5ft. clear span of the arches. Most disastrous of all, however, is the miniature lobby, a maze of doors opening in conflicting directions, the outcome of an ill-jointed plan. Traps of this kind can only be avoided by a close study of actual work, which makes it impossible for you to rough out, even in your preliminary sketches, any feature totally out of scale. A good plan also is to contemplate the passage of the inevitable coffin out of the house, excluding any resort to such drastic methods as taking out the windows, or cutting a trap in floor.

I remember a very practical matron insisting on two labourers carrying a plank along a half-built passage into the mortuary of a Home, in order to satisfy herself of the success of the architect's provision for working round the corners and through the doors. In this connection look after your headroom in those Building Act staircases "enclosed and supported by 9-in. walls." It is surprising how you may be caught out when it comes to carrying up trestle tables, or other long and wide fittings, or furniture. In church work the favourite idea is the pointed door that has a wedge cut out of it because the designer has forgotten to study its revolution in relation to the inner arch. A builder I knew, of some extensive experience of church architecture, was contemplating a lapse in this respect of a certain eminent personage, and his reflection interested me. "Ah," he said, "you would never have caught the late Mr. Pearson like that; no drawing, even of the size of the back of your hand, ever left his office that had not been carefully studied."

Having now somewhat cleared up the preliminaries, we may tackle this main question, What should be the leading quality of a plan?

To answer this, I think we should recognise first of all the existence of different types of plan, and especially the vital distinction between plans that have grown and those which have been, and must be, hammered out at one blow.

This great difference guides us, I think, in the right use of the picturesque—I know that I am treading here on difficult and contentious ground, but on the whole I believe that the great qualities in planning are unity, harmony and subordination arising from logic, order and symmetry.

Nor do I for a moment believe that other than what we know as classical planning is thus excluded, because a close study of apparently utterly irregular plans, conjoined with a knowledge of the requirements, will, I consider, show that those principles are there carried out. The exclusion is of the false picturesque, and the falsely-symmetrical, in both cases chosen for preconceived reasons and not in any way arising from the nature of the case. There is an easy but meaningless symmetry against which you have to be on your guard, a style of planning that has its attractions elsewhere than in the building when erected. Professor Kerr speaks of the beauty of a plan being paper deep.

A plan, however, will not succeed unless the great quality of scale and relations of parts are observed. A grand suite of rooms equal in size, without any centre or climax, will be merely dull, while one of grossly disproportionate apartments will bring ridicule on greatness. The art of combining small and large rooms into a whole is one most worthy of your study.

Hard upon this subject follows the consideration of approach, vista, and climax. Much could be said on all of these if time allowed; on the first, for instance, a whole essay could be devoted to the great question of the relation of architectural grandeur to the human scale, and the limit of exaggeration permissible. I draw your attention to the magnificent grand gallery of Blenheim, occupying an entire wing in plan and section, with the remark that the massive furniture is suggestive of that provided for the dolls' house. Also to the fact that the columns of the façade of St. Peter's, and of those of the portico of the Pantheon, at Rome, of half the scale, are usually judged to be of equal size.

Besides, however, the scale of dimension, there is that of architectural treatment and decoration, and nothing is more painful, I think, than inadequacy in this respect. It is most commonly seen in the glaring contrast of exterior and interior design. A striking instance to my mind is the interior and exterior of Wilkin's fine college in Gower Street, and any number of similar disappointments might be reckoned up.

There is never any harm in specialised features, provided they are not obtained by beggarly meanness in other places. Simplicity of general composition accords well with concentrated richness when the key or ground note of the design is well maintained throughout. It is the shame of the dirt and rags that pours contempt upon the rich waistcoat of the pretentious beggar.

Closely connected is the subject of approach, one more neglected than any other with us. It is strange that it is so rarely noticed that a quite commonplace building may be redeemed by a good approach and setting.

Take as an instance the Madeleine and the Chamber of Deputies in Paris, as united by the Place de la Concorde and the bridge, or observe the effect of the great flight of steps leading up to the Trinita from the Piazza de Spagnia at Rome. In London observe how in the Regency work the genius of Nash produces a certain effect through the laying out, in spite of the utter commonplaceness of the architecture. Not only too in exteriors, but more especially in interiors, is this point lost; for instance, what a loss to the grand interior of St. George's Hall, at Liverpool, is the present use of the lateral entrance from a mere corridor, while the rather unhappy central hall of the Brussels Law Courts impresses the spectator because of the grandeur of the great staircase vestibule that precedes it.

With us considerations of convenience constantly spoil grand effects of this kind; any number of instances exist of large halls entered laterally instead of upon their axes. The great hall of Euston Station is a good instance where this fault has been avoided. One might suggest that we could imitate our own cathedral architects in this respect; for the English lateral entrance porch is a delightful feature in itself, while it is rendered less injurious to the total effect by its position at the extreme end of the side elevation. The whole question of the vestibule and approach is worthy of your most attentive study, and I suggest to you to consider that there is a descent as well as an ascent in scale when you are working out a climax. Of this, two analogies suggest themselves—the Koran shine of a great mosque, and the Holy of Holies of an Egyptian temple.

This paper, you must remember, is intended to draw your attention to the artistic side of planning, and I have already gradually drawn you into the midst of the subject. I suggest you to bear in mind this principle: *In building, section and elevation alone reveal the plan.*

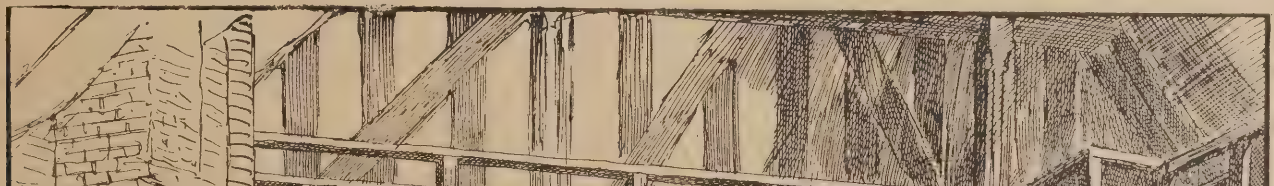
I am certain that if you will as students fully realise the non-existence of the plan, as you have drawn it on paper, you will be greatly helped in your designs. It will change your mental attitude towards plans and planning. You will learn the wisdom of your last-century brethren, who delighted in those quaint drawings, where a plan lies in the centre of four elevations, set up on its boundaries. The $\frac{1}{16}$th and $\frac{1}{8}$th scale studies of your work will consist largely of long sections illustrating the working out of your interiors and their intimate relation to the elevations externally, while a roof plan will be, as it was with Barry, one of the first drawings prepared.

To this add the earliest possible perception of the fact that all architectural effect is dependent on lighting. This is commonly enough remembered for the exterior; but how rare it is to see a well-thought-out scheme of internal lighting! It is not a question of recommending the tricky illumination of some Jesuit church, but of a plea for a reconsideration of the absurd dogma, "You cannot have too much light." Few things are more striking in the Alhambra at Granada than the subtle effect of the distribution of the light, as by the alternation of light and dark bays in the interiors and by other similar means.

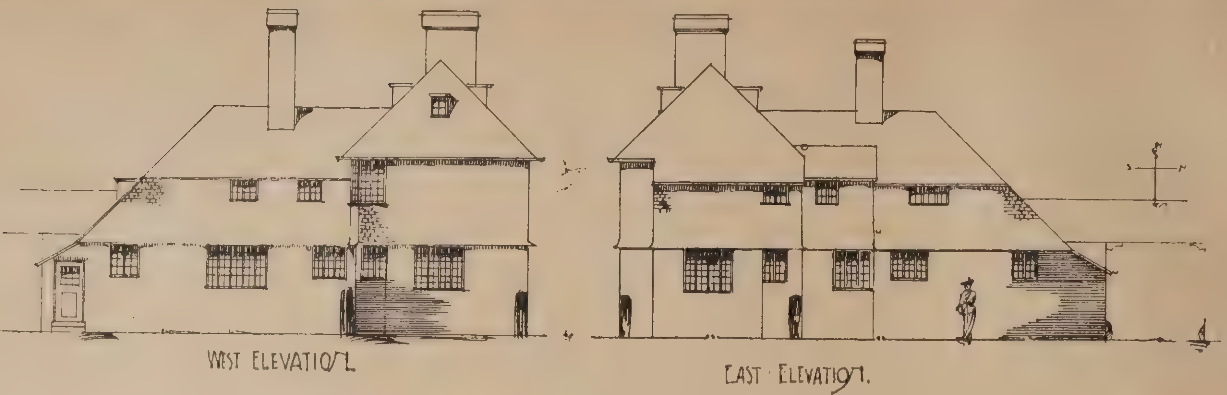
We arrive now at the point where we ought to consider construction as affecting planning. I remember being struck, as a beginner, by the remark of an older student respecting a large modern building that had just been completed in the office. "How interesting," he said, "it would have been if we had had no iron joists and had been obliged to use vaulting everywhere!" The idea was surprising at first sight, as the interior was made up in the main of large rooms, but he maintained that the necessity of providing adequate abutment would have lead to delightful and interesting points of planning and effect.

I do not think there can be any doubt that grandeur in planning is immensely aided by the necessities of monumental construction. In pure planning it is difficult to point to finer examples than the Byzantine, Mediæval, and Renaissance church plans in which the problems of vaults and domes are worked out. It is, perhaps, not easy for us, in such a carpenter's country as England, to realise the extent to which certain styles have originated from the necessities of timberless floors and roofs, but few students would dissociate mediæval work from its characteristic vaulting. I venture, therefore, to strongly advise you, as part of your study of planning, to grapple with the perhaps tedious, but not really abstruse, problems of vaulting. You will find an added interest in your study of old work, and often an unexpected utility in your designs, from an acquaintance with the geometrical principles and methods involved.

One of the questions that was agitated during the Gothic Revival was the legitimacy of cradling, or sham construction, as it was then called. As there has been a return to last-century ideas on this subject on the part of most of us, I assume that the question has been more or less given in favour of the Renaissance rather than the Gothic method. Probably a certain degree of artificiality is inseparable from an advanced civilisation; and if you argue from historic facts rather than from literary theories, it is difficult to prove the proposition that construction has always been rigidly shown. The hollow columns that carried nothing, and the lath and plaster vaults of the Renaissance, were an easy subject of mockery; but the feeling that underlay the use of these features, that of producing a certain effect of beauty is one which lies at the back of all artistic effort. It is a subject of an essay by itself; I only introduce it here to stimulate your thought, and to urge you not to lightly belie your construction, nor, on the other hand, to imagine that a skeleton is necessarily a pleasing object in a drawing-room. The resort to inner ceilings, to the padding-out walls, and other similar means of overcoming otherwise insoluble problems in the proportioning of a complex



ST. STEPHEN'S NATIONAL SCHOOLS, PADDINGTON: IN THE NEW BOYS' SCHOOLROOM, LOOKING EAST.
DRAWN BY F. L. B. GRIGGS. ARTHUR T. BOLTON, ARCHITECT.



GHYLL COTTAGE, GOUDHURST, KENT. ARTHUR T. BOLTON, ARCHITECT.

interior, stands on the same basis as the foregoing. Such things as concealed, or gib, doors, blank windows, and the like, can be far too easily adopted as expedients for economising the time of a planner in a fix.

Probably, apart from monumental planning, the constructive point most likely to come before you in your planning essays is the morality and necessity of observing the ancient law of a "pier over pier and void over void," or its more extended equivalent, the dictum that "walls should follow up," or down as the case may be. I remember hearing an old practitioner inveighing against the methods of a brilliant modern planner in a criticism of a house: "All on false bearings, and you know what that means," was his sharp comment. I fancy steel joists have diminished much of the old feeling on this subject. It was the certain shrinkage of the old timber partition, and the apparently alarming nature of the cracks that followed, that caused such methods to be regarded with so much suspicion. I can only tell you that I have heard, on this question of floors over floors, on excellent authority, that so good a man as the late Mr. Nesfield used to plan out his floors separately, according to the requirements and the aims he had in view, regardless of such considerations, and that then, on arriving at a satisfactory solution of each floor, he pursued a policy of conciliating the differences. Such a method naturally often led to constructive difficulties which were doubtless expensive to overcome. It is, therefore, to some degree a question of cost. You must ask yourself whether the particular point you have in view will thoroughly justify the expense. If, as is very likely to be the case, the answer is in the negative, you must reconsider the whole scheme, so as to arrive at a simpler solution.

As a rule, in a building of more than one floor, circumstances, or your attitude to the problem as a whole, will determine one floor as the master floor; and very often it will be the best to plan out this first, even sometimes down to small points of arrangement, and then to see to what extent the under floors will work to it.

In all country work, or for buildings where grouping is a primary consideration, the roof plan is really the key to the whole matter, and yet how rarely it is that this plan is made out until matters are so far advanced that the worst possible methods have to be resorted to in order to "get over" the necessities of its construction. Knowledge of the simpler problems of intersecting planes is a great help in dealing with roof plans. You may, as you think, come over the facts of geometry in your perspective sketch, and even if your architectural conscience is a slack one, on your ⅛th scale drawings, but science will avenge itself when the building is up. To avoid ruffling up artistic souls I beg to offer you this maxim of philosophy, that "you must obey in order to command," and only by understanding the facts with which you have to deal can you hope to give them that artistic direction at which you are aiming.

The heading of "fads in planning" opens out a delightful field, but we can only cast a glance over it. We all know that ingle nook, staircase, patent service hatch, &c., which have been the bane of our earliest efforts. Gentlemen, those ghosts are not to be laid by the fierce arguments or the most kindly advice of our revered seniors; let them be worked off in a succession of paper designs before we arrive at actual construction.

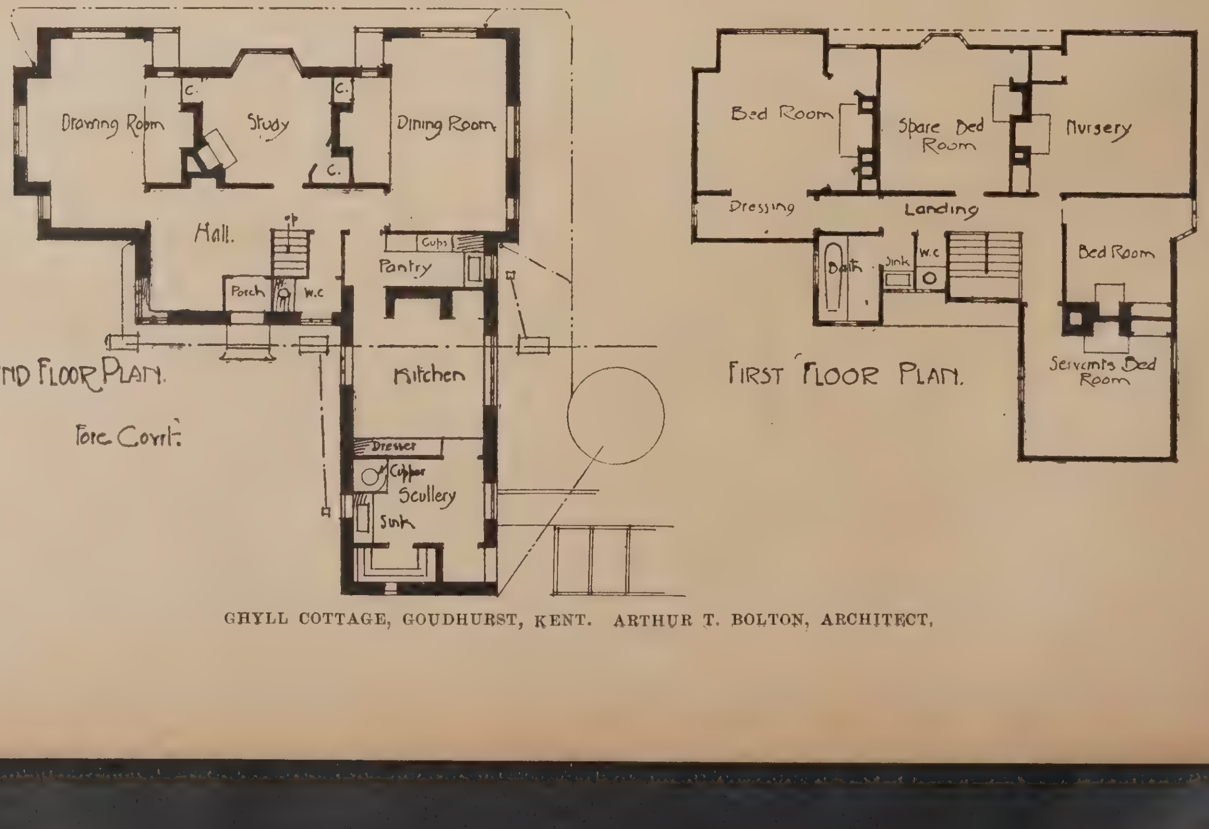
I expect everyone cherishes a special hobby in the nature of a fad. I remember a modern church by a great man to which was attached a hump of a baptistery elegantly labelled by his assistant "a pure example of Mr. So-and-so, of thirty years ago," and I seem to have seen members of whole families of similar features, the outcome of an extensive practice.

I think too that such fads have a respectable antiquity. One might class as great instances many local peculiarities, as, in France, apses and circular stairs, as against square east ends and newel stairs with us, axial as against lateral entrances, &c. For many such peculiarities there were original reasons and traditions at which we can now most often only guess. They are by all means to be respected, and I only mention them here under "fads" in order to warn you against importing such features without reason into unfamiliar places. When this is done they are mere exotics devoid of roots in the soil, and can claim only the interest of those who, by travelling, have acquired a comprehension of their origins and meaning.

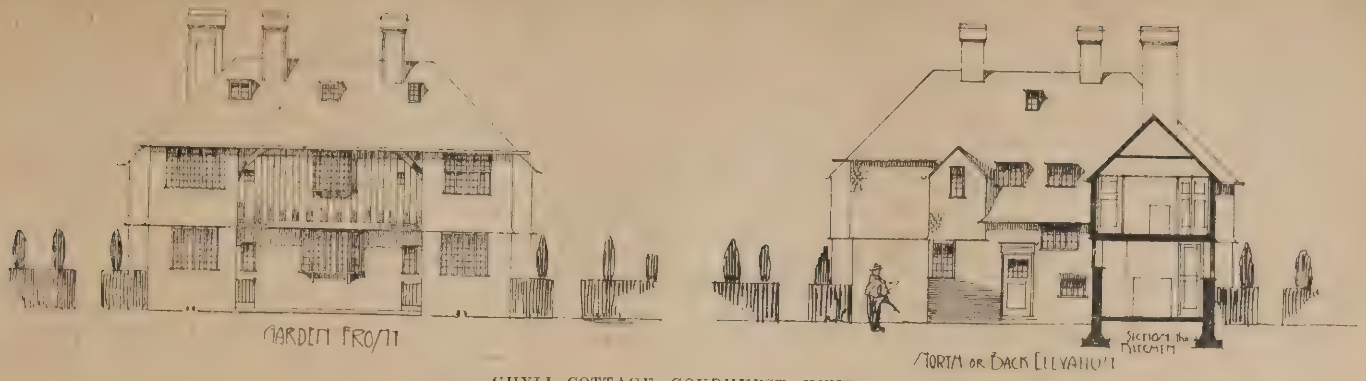
Another kind of fad in planning is the persistence of a feature due originally to some use or ritual that has now become obsolete and has possibly been forgotten. Religious architecture has always, from the earliest days, exhibited numerous instances of this kind. Antiquity has at times given a sacred character to what was at the first only a matter of everyday practice. Fads of this kind are to be handled with great respect, as the links of an ever-lengthening chain that is too precious to be roughly handled. It is needless to excite yourselves, to the point of giving technical explanations, when some too enthusiastic amateur enthuses over the inner meaning of these features of planning.

Not altogether disconnected with the subject of fads is the question of compliance with legislation in planning. Besides the General Acts relating to Building and of Public Health, you ought to have some knowledge of the special regulations that affect various types of buildings through Factory Acts and Education Codes, &c.

Special types of plan are the outcome of such legislation, and until the requirements are altered it will probably be found that such a normal type cannot be safely departed from. This came out clearly in a School Board competition, where all the competitors in vain taxed their inventive powers, being beaten by a scheme closely adhering to the stereotyped plan. If it seems to you that this constitutes an intolerable intrusion of the law into the realms of architecture, I beg you most earnestly to satisfy yourself that the fact is so modern as you believe. I fancy that, on a close study of the facts of old social conditions, you will be surprised to find how much work that you thought to have been done by untrammelled artists was the outcome of obedience to strict regulation. Ask yourself how it is you do not understand offhand the arrangement of, say, some old monastery,

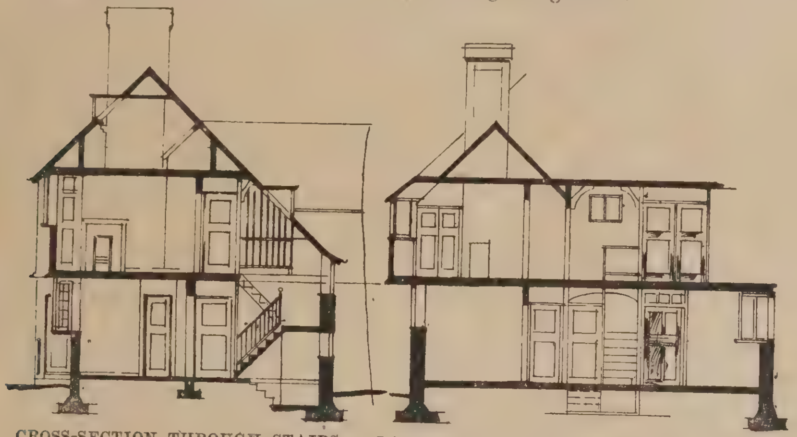


GHYLL COTTAGE, GOUDHURST, KENT. ARTHUR T. BOLTON, ARCHITECT.



GHYLL COTTAGE, GOUDHURST, KENT.

or trace out the effect of the rules of the Cistercian order on monastic architecture, and remember that Imperial Rome had a Building Act as well as London. Such considerations, of course, do not in the least excuse the many vexatious and needless restrictions that architects have so constantly to complain of; they are only suggested so that you may temper your wrath before it leads to the pit of despair. It is needless to resign yourself to inaction on the plea that "the times are out of joint; oh, cursed spite, that I was ever born to set them right," or to adopt the other course of doing anything because nothing matters.



CROSS-SECTION THROUGH STAIRS. PART LONGITUDINAL SECTION THROUGH HALL.
GHYLL COTTAGE, GOUDHURST, KENT.

It will be best for yourself and for architecture if you can find a means to do the very best you can under the circumstances, and we are not entitled to ask you for more.

In the general discussion that followed the reading of the paper several members, including Mr. Doubleday and Mr. C. E. Bateman, took part. The president, Mr. Bidlake, in summing up, remarked that in regard to the point of the section and elevation alone revealing the plan, he had been struck by the extraordinary fact that a few parallel lines of dots in plan could develop into the marvellous interior of a Gothic cathedral.

The Sheffield Society of Architects held its annual meeting last week. Messrs. J. R. Wigfull and J. B. Mitchell-Withers having been elected fellows of the Society, the balance sheet and annual report were passed. It was decided to send to the Royal Institute of British Architects a copy of a resolution that the competition for the late Queen's memorial should have been open to the whole of the British Empire. The following officers were elected: President, Mr. P. Marshall; vice-president, Mr. T. Winder; treasurer, Mr. F. Fowler; members of the council: Messrs. J. R. Wigfull, R. W. Fowler, C. Hadfield, J. R. Mitchell-Withers, E. M. Gibbs, H. L. Patterson (fellows), C. B. Flockton, C. F. Innocent, and C. M. Hadfield (associated members). On the ground that the council needed the infusion of new blood Mr. Gibbs would not accept office, and the vacancy thus created was filled by Mr. E. Holmes. The President handed over to Messrs. H. W. Inott and J. Miller the society's prizes, and Mr. Joseph Smith announced that in future the society would have a home of its own, arrangements having been made to take a room in the building of the Literary and Philosophical Society.

PROTECTION OF BUILDINGS AGAINST LIGHTNING.

A RESEARCH COMMITTEE.

A COMMITTEE, to be known as the Lightning Research Committee, has been organised by the Council of the Royal Institute of British Architects and the Council of the Surveyors' Institution, with the object of collecting and tabulating information from all parts of the country as to damage resulting to buildings from lightning-stroke.

The committee owes its inception to Mr. Killingworth Hedges, who, in his paper on "The Protection of Public Buildings from Lightning," read before the Institute and reported in our issue for April 25th, 1900, referred to the difficulty experienced by experts in getting accurate information as to injuries sustained by lightning struck buildings, and urged the desirability of an enquiry by a recognised authoritative body as to how far buildings are rendered lightning-proof by modern systems of protection.

The present enquiry, by the collection of precise data, may serve to test in some measure the results accruing from the rules laid down by the Lightning-Rod Conference nearly twenty years ago.

The committee is constituted as follows: Chairman, Mr. John Slater; Major-General E. R. Festing (Victoria and Albert Museum, South Kensington), Mr. J. Gavey (assistant engineer-in-chief, General Post Office), Mr. W. P. Goulding, Dr. Oliver Lodge (Birmingham University), Mr. W. N. Shaw (Royal Meteorological Society), Mr. H. Heathcote Statham, Mr. A. R. Stenning, Mr. Arthur Vernon and Mr. Killingworth Hedges (hon. secretary).

In pursuance of their enquiry the committee seek the co-operation of competent observers in all parts of the country, with a view to obtaining accurate details, noted on the spot, of the effect of lightning-strokes on buildings, whether fitted with conductors or not. The committee have held three meetings, and a schedule of questions is in preparation and will shortly be issued.

The following is the kind of information required:—Description and situation of building struck, height above sea-level, position with regard to other buildings and high trees, and propinquity to wells; whether rain was falling at the time—if not, whether rain preceded or followed the stroke, and at what interval; as to the number of lightning-rods on the building, giving position, height above roof, material (both of rod and staples), shape, sectional area, how finished at top and at bottom, condition after flash, &c.; whether conductor was continuous; particulars of earth-connection; when conductor was last examined and tested; nature of soil; the precise nature of the injury to the building; if any portion was set on fire; damage to metal-work, such as bells, rainwater and other pipes, electric bells or telephones; distance from conductor of portion of building affected; materials of roof-coverings, and position of gutters and down-pipes; whether conductor was in contact with any other metal; particulars as to metal-cresting, weather-cocks, finials, or flag-staffs on the building, stating distance from and height above conductor; if conductor was struck, whether damaged portions can be obtained for examination, &c.

Members and others willing to assist the Committee by their observations are requested to communicate with the Secretary of the Committee, at the offices of the Institute, 9, Conduit Street, W.

Surveying and Sanitary Notes.

"The Scientific Roll" is a most useful magazine of systematised notes, issued periodically. Number two, on Bacteria, has just been published, price 1s., and gives a list of the bibliography appertaining to the subject, with a record of the facts dealt with.

The Proposed Bacteriological Institute for Dublin is meeting with the support of the Irish public bodies. It is thought that it should be a national one, supported by all the public institutions and sanitary authorities in the country. We understand it is proposed to establish in Dublin a Pathological Institute in connection with all the lunatic asylums in Ireland. As the work of such an institute will be mainly bacteriological, the Dublin Corporation Public Health Committee think that one institute will suffice.

Law Cases.

Respecting a Brick-Kiln.—Messrs. Joseph Morton, Limited, of Siddall, were recently summoned at the Halifax Police Court for erecting a brick-kiln at Cinderhills without having first submitted plans to the Corporation. The defence was that the kiln was "used exclusively in connection with the working of a mine," and therefore exempted under clause E of by-law 2. The case, which occupied the Court several hours, turned wholly upon the construction of such exempting clause. Mr. Tordoff, Assistant Town Clerk, said that the point was this: Was this kiln used for something connected with the getting of clay out of the soil? He submitted that it was obvious on the face of it that it had nothing whatever to do with it. The clay, after being got from the mine, was not taken directly to the kiln; it had to undergo a variety of processes before being burned in the bakery or kiln. Mr. Walter Storey, in defence, urged that the mine, in which was coal as well as clay, could not be worked at a profit unless they had the kiln close to—and therefore in connection with—the working of the mine. The Bench were unable to agree, and the case has to be re-heard. The re-hearing has been fixed for May 14th.

The Definition of a "Dangerous" Building.—At the Manchester County Police Court on April 4th Mr. J. M. Yates, K.C., the stipendiary magistrate, gave the decision of the Bench in the case of the *Swinton and Pendlebury Urban District Council* v. *Watson, Woodhead and Wagstaffe*, brewers. Two days before, Mr. Postlethwaite, the clerk to the Council, applied to the Bench for an order, under section 32 of the Housing of the Working Classes Act, 1890, to close the British Queen Inn, North Dean Street, Pendlebury, on the ground that it was in a state so dangerous or injurious to health as to be unfit for habitation. One of the walls was 13in. out of the perpendicular, and another fronting Dean Street was 7in. out; some of the cross walls were broken and bent, and one of the floors was 18in. lower at one end than the other. It was contended for the defendants that the Act did not apply to houses such as this, and that, if it did, that "dangerous" meant dangerous in a sanitary sense. Mr. Yates said that the definition of a "dwelling-house" in the interpretation clause defined it to be any inhabited building, and included the site. It was impossible to say that this was not an inhabited building, and it was not for them to limit the wide definition of the Act. Then, did "dangerous" mean in a sanitary sense? The section of the Act did not so limit it, but it said "dangerous, or injurious to health," and they thought the section meant to deal with two sorts of property—one that was dangerous, and one that was injurious to health. It was clear that, if unoccupied, the sanitary condition of this house would not be likely to affect the inhabitants, but its dangerous condition might well do so. The Bench ordered the house to be closed. A case was granted.

A Building Trade Dispute: Picketing.—A case arising out of the building trade dispute in Belfast was investigated at the local Police Court on April 9th. An action was brought by an alleged "blackleg" named M'Gimpsey against a striker named Maguire. The plaintiff said that he was beset and intimidated while at work, and after he left off was hooted by a crowd of strikers, of which the defendant appeared to be the ringleader. On April 1st the defendant had also been arrested for disorderly conduct in the street. Mr. Hodder, the stipendiary magistrate, in fining the defendant £5, said that had it not been the first case he would have inflicted a long term of imprisonment.

Bombay's Consulting Architect.—The India Office have chosen Mr. John Begg, A.R.I.B.A., for the position of Consulting Architect to the Government of Bombay from two applicants selected by Mr. William Emerson, President R.I.B.A.

The Statue to the late Most Rev. Lord Plunket Protestant Archbishop of Dublin, which has been executed by Mr. W. Hamo Thorneycroft, R.A., was unveiled yesterday in Kildare Place, Dublin.

Catalogue Art. — Messrs. Spottiswoode & Company, Limited, printers, of New Street Square, E.C., have just issued a catalogue giving specimens of the work they are doing in producing trade catalogues. The production of these articles is worthy of a greater amount of consideration than is usually bestowed upon it. Although considerable sums are at present spent in printed catalogues, the standard remains very low, and it is certain that if manufacturers were to give the matter into the hands of a firm such as Messrs. Spottiswoode, who lay themselves out for artistic work, benefit would be derived by all concerned. This firm are prepared to undertake the complete production of any class of catalogues, and are prepared to submit sketches, suggestions, specimens, and estimates free. The catalogue under review shows how attractive these necessities for the manufacturer and merchant may be made, and we advise everyone who is thinking of having a catalogue printed to write for a copy of this one; the advice given in the introduction is good, but the setting of the type shows the very easy mistake of having too much red ink on a page, and also of putting splotchy initial letters in the middle, thus destroying all balance of type in the page.

QUEEN VICTORIA MEMORIAL.

THE VIEWS OF LEADING MEN.

THE BUILDERS' JOURNAL was almost the first to publicly decry the decision of the official committee to restrict the competitors for the Queen Victoria Memorial, and we are glad to see that this decision is meeting with increasing disapproval in the daily press. The "Daily Chronicle" especially has devoted considerable space to the matter.

Mr. Norman Shaw's Opinion.

To a representative of the "Chronicle" Mr. Shaw said he felt that, reviewed from a national standpoint, the Executive Committee had carried out its work in a most unsatisfactory manner. The selection, which he took to be the result of the committee's labour, was but a compromise at best. First of all, the committee appeared to have selected three Englishmen. Then, in order to allay national jealousy, they threw in a Scotsman and an Irishman. Mr. Shaw foresaw endless trouble and confusion for the committee, who had not gone to work the right way. He considered it would have been much better if the competition had been an open one. Then a jury of specialists could decide which was the best design. As it was, who was going to sit in judgment upon the designs to be submitted by the gentlemen chosen by the committee; and how were they to know that any of the work would prove worthy of so great an occasion? It would be necessary, he considered, for a body of experts to report upon all the designs, and this body should be empowered to reject them all if they fell below a certain standard of excellence.

"English architects of to-day know nothing of monumental work," said Mr. Shaw. "This is perhaps because they have done so little of it. That little has been done badly. In this respect there is a vast difference between ourselves and the French and the Germans. Our best work is domestic architecture, theirs monumental. In the hands of people who could design the Arc de Triomphe and the magnificent votive church at Montmartre, such a work as the Victoria Memorial would be perfectly safe. With every respect for the five architects chosen, I must say that they know as little of monumental work as anyone in the profession, although Dr. Rowand Anderson did some splendid work when he designed Edinburgh University."

Asked what he considered a suitable form for the proposed memorial, Mr. Shaw said he thought that the object the committee had in view might be achieved by the erection of a new facade to Buckingham Palace, and the incorporating with it of a suitable statue of her late Majesty. This (re-naming the palace "Victoria") would be a memorial, useful, stately and ornamental.

What Mr. Charles Holme thinks.

Mr. Charles Holme, the editor of the "Studio," says: "That this great national memorial should be placed in the hands of any small group of men, no matter of whom composed, must seem a grievous error to all who have an extended practical acquaintance with the working and results of open competitions.

"The scheme devised by the council should in the first instance be made widely known, and the whole profession of architects invited to submit preliminary plans and sketches. A selection of the more suitable designs received should then be exhibited. It is by no means certain that the men whose names are the most generally recognised will produce the most worthy and acceptable projects.

"Great Britain at the present time is remarkably strong in the possession of a brilliant generation of young and rising architects, sculptors and decorators. Let these lesser-known workers have an opportunity of showing their capabilities. It is admitted throughout Europe that, had their productions been adequately exhibited at the World's Fair in Paris last year, we should not, as a nation, have suffered the humiliation of being ranked as low as we were in the scale of artistic merit."

Mr. Onslow Ford's Idea.

Mr. Onslow Ford suggested to a "Chronicle" representative that "a good way of carrying out the scheme would have been for the committee in charge to appoint a sub-committee of the sculptors belonging to the Royal Academy. The sculptors would have had power to call in an architect, as chairman, we shall say, and a scheme would have been worked out by collective effort."

The Views of Mr. Pelcher and Mr. Flockhart.

Mr. John Belcher is of opinion that it would have been well if the design had been open to competition. "But it is possible—and the point is not to be overlooked—that this would have kept out some well-known men. What I mean is that, as very busy men, they might not have cared to enter upon a purely speculative task. But, even allowing for that argument, I think the present list is rather limited. Indeed, if I may so, I fancy that the selection of one architect, like Mr. Norman Shaw, would have given greater satisfaction to the profession."

Mr. William Flockhart holds a similar view.

Mr. G. F. Bodley makes a Suggestion.

Mr. G. F. Bodley, in a letter to "The Times," thinks that the memorial should rise out of the lake in St. James's Park. "Not, however, isolated, but connected with either bank by a bridge of a sufficient but not too great a width. This should have light and graceful arches. At either end of this bridge-road there could be a flight of steps and an archway with statuary and heraldic bearings and bronze gates. Statues might also be placed on the piers of the arches of the bridge. In the centre the memorial would rise four-square or octagonal, its base rising from the water. The lower part could be of red or grey granite, and the whole of the superstructure of white marble, with bronze statuary. It could be made a beautiful object in a beautiful situation."

Mr. Haité's Opinion.

In the course of an interview with a "Daily Chronicle" representative, Mr. George C. Haité, president of the Society of Designers, said he doubted if an architect was the best qualified designer of a national monument. His work lay more in the planning and building of habitations and business premises than in designing national memorials. Such work, Mr. Haité thought, would be much better carried out by the architect working in conjunction with the artist-designer and the sculptor; for a memorial called for artistic conception and treatment of design. In order to enable the representative men of the kingdom to compete if they desired, Mr. Haité would have the final selection of the design left to a committee consisting of French, German, Italian, and American architects.

Mr. D. S. McColl's Views.

Mr. D. S. McColl holds such a high place as an art critic that his remarks on this subject are particularly valuable. In the "Saturday Review," referring to the five selected architects, he says: "If these five gentlemen are chosen, at least twenty more have a right to feel aggrieved at being excluded.

"Mr. Jackson is a man of learning and taste, whose work at Oxford was much more sympathetic with its surroundings than the disfiguring additions by earlier hands. His vein has been a little overworked, perhaps, but it is conceivable that his ingenuity and taste, concentrated on this project, might produce a pleasing monument. His might very well be one of a dozen names.

"Mr. Aston Webb is an able organiser of buildings, whom no one, probably, would call a great artist. His hands and those of his staff must be full with the additions to the South Kensington Museum, and the kind of ability displayed in those additions is not what is wanted for so special a monument as the memorial.

"Mr. Ernest George is a still more surprising choice in so limited a number. His mind is that of the picturesque sketcher rather than of the monumental architect. He has enlivened certain London quarters with reminiscences of foreign travel, but the signature of a native architectural character is always missing.

"The remaining names on the list reveal the compromising committee-mind that has drawn it up. Three names have been chosen from England, therefore one must be thrown in from Ireland, and one from Scotland. Sir Thomas Drew's work is little known in England; Dr. Rowand Anderson is of the able organising type, and has attracted a good deal of talent to his office; but clearly these two names were put down as official heads of the profession in the two countries to give a look of impartiality all round.

"If I have fairly stated the claims of the five competitors, it will be clear that the scheme is an unsatisfactory official compromise between two ways of doing the thing. No one would complain if one of the first-rate artists in the profession had been chosen and given the commission to make the best of. Thus I am convinced that every artist in the kingdom would have acquiesced if Mr. Norman Shaw had been invited to undertake the project . . . But such a decision would require in our rulers both taste and the courage of taste, and they have neither. It is better certainly not to have the courage without the taste, as is the case with the German Emperor, imperiously loading the earth at Berlin with his idea of heroic statues. But not very much better is the decision reported, which amounts to an advertisement of want of conviction.

The Great Genius of Alfred Stevens.

"Sir William Harcourt the other day repeated a familiar refrain about the wretched character of our public monuments. He forgot that we have one superb monument, and that obtained in public competition. It was obtained more by luck than judgment, it is true. Others gained the premiums, and the design of Stevens finally came to the front because it turned out to be the only one that fitted under the arch. Our luck trembled, it will be seen, on a precarious chance, but there always is that chance, the probability that talent will win at one point if not at another, and escape, by sheer efficiency, all the guards of stupidity.

"There is another reason, apart from the final choice of a designer, in favour of such a competition. A memorial like this stirs the imagine ation, and nothing would put more life into the schools of architecture and sculpture than emulous effort centred on such a monument, and crystallising the theories and tentatives that are groping for a style. It is quite conceivable that one of our younger architects might strike out a memorable design, certain that the effort on all sides, as in the old fresco competitions for the Houses of Parliament, would be quickening and educational.

"Nothing has been said so far of the choice of a sculptor. Here the committee are credited with a single choice, that of Mr. Brock. Mr. Brock will certainly do nothing offensive; his work will be preferable, in a negative way, to the photographic and arts and crafts fashions in sculpture; but he will as certainly do nothing inspired. There have been two memorable designs for a statue of Queen Victoria. One was the project by Alfred Stevens for a monument of the Great Exhibition. It can be seen at South Kensington. If this had been carried out the Queen would have had a monument indeed, and it is to be wished that some sculptor of the needful modesty and ability should even yet take it in hand. I recommend the idea to committees up and down the country. The group of continents that encircles the pedestal is a ready symbol of empire, and the younger Queen might stand for history's and the sculptor's sake. The other monument was Mr. Alfred Gilbert's at Winchester. Some demon plays havoc with many of Mr. Gilbert's designs, but this was a royal one. Is it incredible that England should throw up yet another sculptor; and was it not worth while searching for him? Nothing is more superfluous than middling sculpture on monumental architecture, and I argue in the hope that the reported scheme is not authentic or finally determined on. It would be too stupid to close all loopholes against genius."

The "Times" supports the Committee.

In a leader on the Memorial the "Times" expresses the opinion that "whatever may be the ultimate design, a memorial which is to be a worthy symbol of a nation's affection, the durable testimony of its sorrow. cannot be dealt with as if it were a contract for the supply of forage or the erection of barracks. It is found in practice that the best artists hold aloof from such competitions. They prefer to go their own way, and do not care to take the risks of a competition in which their merit may not be recognised. However carefully constructed may be the tribunal of adjudication, it is notorious that a design with certain obtrusive, perhaps tricky, qualities has a better chance than another which will be permanently more satisfactory as a work of art. Out of such a contest comes something respectable and mediocre, something costly and showy, but rarely anything better. And, then, what tribunal likely to be trusted by the multitude of competitors could be formed? The chances are that it would only escape the charge of favouritism by incurring that of incompetence . . .

"Unfortunately, there is no great choice of sculptors. We are often told that at last their art is flourishing among us, and that in a few years we may look to seeing a score of men fit to be entrusted with any national work. But . . . it generally happens, when a statute interesting to the whole nation is required, that only one or two are available, and that the result is indifferent."

Mr. Lionel Cust on Sculpture.

Mr. Lionel Cust writes to the "Times" in reply to their leader, "which seems somewhat unduly pessimistic in its view of the condition of the sculptor's art in this country at the present day.

"The art of sculpture has had a chequered existence in this country, and there have been times when it has nearly perished from inanition or from the outrageous demands made upon it by its so-called patrons. At the Royal Academy Exhibition the sculptor's art is relegated to a room by itself, where the decorative qualities of the art so essential to its existence are hardly to be perceived.

"It is, perhaps, scarcely known to the general public that of all the arts that of the sculptor is the most costly to the actual artist. A sculptor cannot afford to carry out large works in marble and bronze on the mere change of their finding a purchaser. He is compelled to wait for commissions, and cannot afford to neglect any opportunity for exercising his art in a profitable way. Hence it comes about that anything of an original nature in a work of sculpture is seldom produced in this country, where the æsthetic and decorative aspect of the art is ignored in favour of the merely monumental.

"At the present day there is in this country a school of sculptors, capable of producing artistic work, which can compete with any school of sculptors on the Continent, or, indeed, anywhere, within the last 150 years. They only lack opportunity and encouragement. If the public demand monumental statues of gentlemen in frock coats standing on drums or packing-cases, our sculptors must supply them, for otherwise they might fail to earn a livelihood. But, be they Phidias, Michelangelo, or, Rodin, they can but produce one result — that of inartistic monotony.

"The proposed scheme for the National Memorial to Queen Victoria affords an opportunity to our sculptors which has never occurred before. That the central group, or figure, should have been entrusted to Mr. Brock, R.A., is intelligible to all who are acquainted not only with that sculptor's work but with the esteem in which he is held by his brother artists.

"Should, however, the funds contributed enable the committee to decorate not only the new square, or piazza, but also the new road through the Mall with groups of sculpture, it can be said with the utmost confidence that for each group required there could be found at the present moment a separate sculptor capable, if unfettered by circumstances, of producing a work worthy to rank among the great achievements of the sculptor's art."

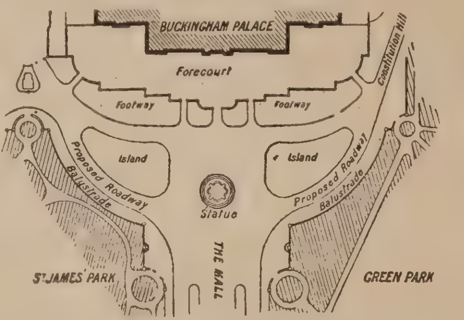
An Advocate for Two Competitions.

Mr. A. H. Skipworth says: "The utilising of a statue already (as I understand) executed suggests the second-hand lumber-shop. The national monument is apparently to be a design created specially to enshrine this piece of sculpture. Such a course is likely to considerably hamper the competing architect, who will find himself absolutely tied down to a certain sized figure for the all-important and central feature of his creation. It seems to me that there should be two competitions. The first open to all, and the second confined to a limited selection from the first. Each architect in the second to be paid for his services; and at the very least five competent assessors, the names of these to be published with the conditions. It is unfortunate, however, that, owing to various causes, competitions at the present time are not favourably looked upon by architects."

Let the Architects and Sculptor Resign.

The art critic of the "Chronicle" remarks that "all the talk last week among artists and architects, in private as in public, was on the subject of the Queen Victoria Memorial. Even little informal indignation meetings are reported to have been held, from which something may yet be heard. The almost universal opinion, expressed in private as in public, is that the committee have made a hopeless blunder. The present scheme has been met with such widespread and earnest protest that if the committee refuse to reconsider it, the only possible course left would be for the five architects and one sculptor to resign a commission finding favour with no one, and themselves propose a competition open to all British artists. They could do nothing that would make them more popular."

The "Daily Telegraph" published last week a plan showing the arrangement (? authentic) of the Buckingham Palace site. This we reproduce. It is not the official one; but it certainly seems to embody the chief proposals, and is therefore of considerable interest at this time.



Mr. William Woodward.

In a letter to the "Times" Mr. William Woodward has not a word to say against either of the five gentlemen nominated as architects, nor against the capable and distinguished sculptor who has been named, "but surely there can be no reason why all British architects should not be permitted to send in drawings and models to be considered by a competent committee of taste. The five architects have had no opportunity whatever in the past to show any particular aptitude for the character of design now required—which is quite outside ordinary building design—and it would be interesting to know how it came about that the committee were able to place their fingers upon the chosen few.

"Personally I feel the disappointment great, because for the last fifteen years . . . I have shown the opportunities which exist in London to make it a beautiful city, and more particularly have I devoted my attention to the opening of the Mall to Charing Cross and the laying out of Trafalgar Square as a public garden.

"On March 11th last I forwarded to Lord Esher a complete design for dealing with the Mall next Charing Cross and with Trafalgar Square as a fitting memorial to Queen Victoria, and that design I shall now publish."

A Recollection and a Hint.

Commenting on this letter, Mr. Richard Edgcumbe recollects incidents in connection with the carrying out of Mr. Disraeli's proposal to erect a national memorial in honour of Lord Byron. "More than a quarter of a century has elapsed since, by orders of my committe, I invited sculptors from all parts of Europe and from America to compete for what must, after all, be considered a small matter by comparison with this proposal fittingly to commemorate the personal character and achievements of Queen Victoria and one of the greatest chapters of English history.

"In response to the appeal made by the Byron Memorial Committee, under the advice of three or four celebrated sculptors—who, of course, did not themselves compete—sketch models arrived from every corner of Europe. Artists, in fact, of every nationality gave us an example of their plastic conceptions . . . Two public competitions took place . . . The result in both cases was so unsatisfactory that the committee, in order to save a further waste of time and money, felt bound to elect the best among the submitted models—with what result may be seen by anyone who passes along the railings of Hamilton Gardens!

"As a matter of fact, these public competitions are futile. If one could divest the artist's mind of a suspicion that favouritism will, somehow or other, operate in the ultimate selection of a design (no easy matter), there would still remain the feeling that his work will be judged by persons having preconceived notions as to the form which the memorial should assume. Under these circumstances a competitor feels the greatest possible restraint in carrying out his own conception, fearful (and not without cause) that the best work will be set aside by incompetent or prejudiced persons in favour of a design more in harmony with their peculiar notions of appropriateness."

Two Names Omitted.

Another correspondent of the "Chronicle" expresses great surprise that the name of Mr. Norman Shaw should have been omitted from the list of selected architects: "It is amazing to read one of your correspondents quoting Sir William Harcourt on the architecture of our British monuments, for it was Sir William who said that he could not see the difference between New Scotland Yard and the neighbouring soap-works. It is of course possible that Mr. Norman Shaw is reserved for the assessor's committee.

"Another name one would have liked to see is Mr. H. Wilson's. Mr. Wilson's work is not perhaps so familiar to the public, although for years he has monopolised the place of honour in the Royal Academy architectural room. To those who know his work, his wonderful control of sculptural and colour schemes, his masterly handling of the details (misealled ornament), especially in the weaving-in of naturalistic and symbolic forms, would have commended him as the first person to design a monument requiring in its designer just these artistic faculties."

Small Sketch Models.

Mr. James Begg suggests that the committee should invite artists to send in designs, accompanied by small sketch models.

"The jury should then select a few of the most meritorious designs sent in, and invite the successful artists to again submit their ideas in a more complete form, granting them at the same time sufficient money to cover the cost of preparing complete models and working drawings."

A Molehill—not a Mountain.—Last week the fact leaked out into the daily press that a short time ago a column in Westminster Abbey fell and was broken. First of all it was "a pillar at least 18ft. in length," and if one had no other information than that produced under the pen of a "descriptive" reporter in search of sensational "copy," one would be led to think that the interior of the Abbey was in a very parlous state—might fall in perhaps—and bury the reporter! But the pillar became smaller and shorter, and eventually, when the actual fact was ascertained, it proved to be an ornamental window shaft of Purbeck marble, 3in. in diameter and 5ft. long, in the chapel of St. John. In falling, the shaft smashed some hot-water pipes and damaged the tomb of Sir Henry Norris. There is, of course, no danger of the Abbey collapsing, though it is only to be expected that ornamental features of this kind—being, by their very nature, delicate and fragile—will not last for all time. The foundations of the Abbey are sound, and the interior is inspected and examined regularly, so there is little fear of a collapse. Too much attention has been directed to this trivial incident. It is perhaps opportune to mention that the Abbey will be closed for three months, in order that the preparations for the Coronation ceremony may be carried out. These preparations include the casing-in with wood of the pillars, in order that they may not be injured by the great crowd that will assemble there to witness the crowning of their King. The Abbey was closed for two months in connection with the Jubilee of 1887.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Concrete in which Nails can be Driven.

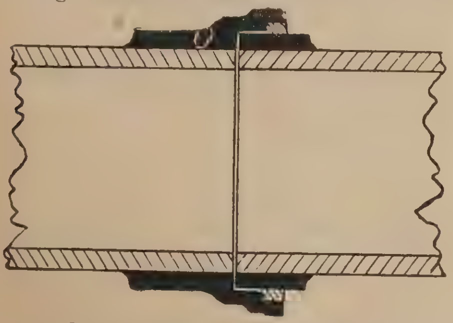
NOTTINGHAM.—QUERIST writes : "What are the proper proportions for mixing coke-breeze and Portland cement so that nails can be driven in for fixing joinery ? "

The proportions vary according to the nature of the coke-breeze. 1 part of Portland cement to 5 of a hard breeze and 1 part of Portland cement to 7 of a soft breeze gives good results. If there is time for the mass to set before being moved from the moulds the addition of an extra 2 parts of breeze, soft or hard, may be safely used. The breeze should be crushed before use. W. MILLAR.

Laying Sewer in Water-logged Ground.

GUILDFORD.—BUONOPARTE writes : "A sewer is to be laid at a depth of 11ft. in water-logged ground (water within 4ft. of surface) and running sand. How can this best be done ? Stoneware pipes with Hassell's joints have been recommended on 6in. of cement-concrete ; others, afraid of the sand and water, propose Shone's ejectors. The line of sewer proposed is near the river, in a low part of town, where the water gravitates from the hills around. Which method would you recommend for adoption ? Would £1 per yard run be a fair price for the stoneware pipes sewer ?"

In designing a sewerage system for a town situated in a flat low-lying district with water-logged subsoil, it is frequently advantageous to adopt Shone's or Adam's well-known arrangement for raising sewage to higher levels at various points. If, however, only an isolated or inconsiderable length of sewer requires to be laid in wet and treacherous ground, then it is generally advisable to incur the extra expense of overcoming the difficulty, rather than make provision for a heavy annual charge in the maintenance of sewage lifts. When laying drains in water-logged ground, sump-holes should be formed at intervals along the trenches, from which the water may be removed by pumping. Sometimes before putting in the concrete bed a line of small diameter drain-pipes is laid from the sump-hole along the bottom of the trench, so that the water-level may be kept below the invert of the sewer whilst the pipes are being laid. In very soft and yielding ground a 6in. concrete bed is usually found to be inadequate to secure a firm foundation. For situations where much ground-water is met with we should recommend cast-iron pipes with turned and bored joints. Recently we had occasion to construct a line of sewer through quicksand at a depth of 18ft. from the surface, the ground being completely water-logged and necessitating heavy steam pumping. Efforts were first made to carry the sewer on a 12in. concrete bed laid on 3in. planking spiked to longitudinal bearers, but without success. Eventually cast-iron pipes, with turned and bored joints, were supported on cast-iron screw piles, screwed into the quicksand at the bottom of the trench. The pipes were arranged with three strong bolt-lugs cast on each end, so that a perfectly tight joint was ensured by securely bolting the pipes together. Drains having Ernest Smith's patent iron joint for stoneware pipes are also readily laid in wet ground (see sketch). These drain pipes consist of butt-ended glazed stoneware pipes, having a light iron spigot and socket securely cemented to the ends of the stoneware. When placed in position, the pipes are quite concentrical, and the joint is made watertight by caulking a strip of solid-drawn blue lead into the annular space between the spigot and collar. Lead strips of the proper length and thickness are provided with the pipes, whilst the pipes themselves are made in 3ft., 3ft. 6in., and 4ft. lengths. For stoneware pipes which are required to be laid in wet trenches, Hassell's patent double-lined joint is one of the best that can be adopted. A price of 17s. to 20s. represents the average cost of constructing ordinary sewers, including manholes, &c., complete ; but for sewers laid in difficult ground, where continual pumping or additional foundations would be necessary, the price must be increased by 25 to 100 per cent., according to the local conditions. T. E. C.



Model By-laws and Party Wall.

GUILDFORD.—BUONOPARTE writes : "The Model By-laws allow the insertion of no plate, block, or plug of wood in a party wall ; *i.e.*, in cases of lean-to back offices and rooms of dwellings two distinct plates will be required. How can the top of the wall be covered satisfactorily ? No ridge tile is sufficiently broad to efficiently protect wall rafters and slates."

All party walls should be carried up *above* the adjoining roofs, and finished with a brick-on-edge or stone coping. The joint between the wall and the slate or other roof covering should then be finished on each side with lead flashings in the usual manner, so that the roofs on both sides, the party wall may be quite watertight.

T. E. C.

Book on Honours Building Construction.

BIRMINGHAM.—A. F. Z. writes : "Kindly name one or two books on Honours Building Construction. I want if possible to get a cheaper book than Rivington's, which is 21s."

"Building Construction (Advanced and Honours Courses)," by Charles F. Mitchell, price 4s. 6d., is a good book. It is published by Mr. B. T. Batsford, of 94, High Holborn, W.C.

Book on Wren's Towers.

DERBY.—VOLUTE writes : "Where can I obtain a book illustrating Wren's towers ? I remember seeing such a book several years ago—a small one, with illustrations and hardly any letterpress—and I believe that the title was 'Wren's Towers ?' "

"Wren : The Towers and Steeples designed by Sir Christopher Wren," by A. T. Taylor, A.R.I.B.A. (price 3s. 9d.), is probably the book you mean. It can be obtained from Mr. B. T. Batsford, of 94, High Holborn, W.C.

Sanitary Institute and Examinations.

PAISLEY.—W. L. writes : "What books would you recommend for study for the examination of the Sanitary Institute for sanitary inspectors ? Also, when are the examinations held ?"

Apply to the Secretary, Sanitary Institute, Parke's Museum, Margaret Street, W.

Little Stanmore Church.

BOLTON.—TWOPENCE A WEEK writes: "Please state where I can obtain a description of the old brick church at Stanmore. There is also a vault inside the ruins, I believe, about which I should like some information."

The church of St. Lawrence at Little Stanmore was, with the exception of the tower, built about 1715, and, while vaguely said to be in the "Italian" style, is probably of the English Renaissance which was in vogue at the time, and which was that of the later years of Wren's lifetime, the *true* "Queen Anne." Several well-known artists seem to have been employed to decorate the church, including Antonio Verrio, Belluchi, Laguerre, the carver Grinling Gibbons, and his father-in-law, the iron-worker. The organ was also built in Queen Anne's reign by Father Schmidt, and was re-built and enlarged in 1878 ; but some of the carving on the case is the work of Grinling Gibbons. The mortuary chapel (probably the vault referred to in the query) was also decorated with wall paintings by Verrio. G. A. T. M.

Latin in R.I.B.A. Preliminary Examinations.

SOMERSET.—R.E.G.A., writes : "Kindly name the book from which the Latin sentences set in the R.I.B.A. Preliminary Examinations are taken. It appears to me that they are taken from Æsop's Fables."

Speculation as to where examination questions are taken from, is most unwise. More failures result from "cramming" of this sort than from any other cause, for the examiner has the whip-hand of the examinee, and can readily circumvent the man who has merely crammed a few likely pieces of translation. The only proper course to adopt is to master the Latin language sufficiently to be able to translate simple prose at sight—a feat which should be within the capacity of any fourth-form boy from any public school. G. A. T. M.

Books for S.K. Examinations.

LLANELLY.—STUDENT writes : "Kindly mention some books suitable for study in the following subjects held at South Kensington (Art Department) : Architecture, Architectural Design, Principle of Ornament and Historic Ornament. Do you consider that in studying the above in preparation for the May examination, 1902, I should have too much in hand ? "

The "History of Architecture," by the late Banister Fletcher and B. F. Fletcher, is a useful summary, but you ought to read Fergusson's work. For ornament, study Meyer's "Handbook of Ornament" (10s.), Dolmetsch's "Historic Styles of Ornament" (25s.), and Mr. Walter Crane's "Bases of Design" (18s). Architectural design cannot be learnt from books ; you should study old buildings and new ones by acknowledged masters, and read Ruskin's "Seven Lamps of Architecture" (7s. 6d. nett), Viollet le Duc's "Dictionnaire Raisonné de l'Architecture," and "Stones of Venice" (3 vols., 10s. nett). These books can be obtained from Mr. B. T. Batsford, 94, High Holborn, W.C. There should be time for you to study these for the 1902 examination.

Timber Marks.

PLYMOUTH.—G. A. writes : "(1) Where can I obtain full information of the current marks (or brands) on imported timber ? Is there such a paper as the 'Timber Trades' Journal' list of shipping marks ? If so, kindly inform me where to obtain it, and the price. (2) What is the usual method of setting out a building, after bottoms are out ? Should the measurement be taken by rod or tape ? "

(1) The "Timber Trades' Journal" list of shipping marks on sawn and planed wood exported from Sweden, Norway, Finland, Russia, and Germany is published by Messrs. William Rider & Son., Limited, of 14, Bartholomew Close, E.C., price 6s. (2) With regard to setting-out a building after the foundations are put in, start at one corner and build up a few bricks, then measure off the length of one wall carefully to the next corner, a rod being preferable to a tape. Build up a few more bricks, using a large set-square made by nailing two pieces of board together, with a cross-piece to keep them in position, and level with the first corner. Proceed in this way round the building ; the corners having been built up, the bricklayers can stick in their pins and lines, and proceed merrily.

Building Trade in New Zealand.

HEXHAM.—D. S. writes : "In what issue of the BUILDERS' JOURNAL did an article appear on the building trade in New Zealand ? "

An article on "Architectural Art in New Zealand," by Mr. S. Hurst Seager, A.R.I.B.A., appeared in the R.I.B.A. Journal for September 29th, 1900, and particulars of the state of labour in the building trades in that country will be found in our "Masters and Men" column this week.

Books on Italian Renaissance Architecture.

BURNLEY.—STUDENT writes : "What books are required for the study of Italian Renaissance architecture, and what are the characteristics of the Roman and Venetian Schools ? "

"Architecture of the Renaissance in Italy," by W. J. Anderson (price 12s. 6d. nett), and Ruskin's "Stones of Venice." (3 vols., price 10s. nett), will give you the information you require.

Bricks and Mortar.

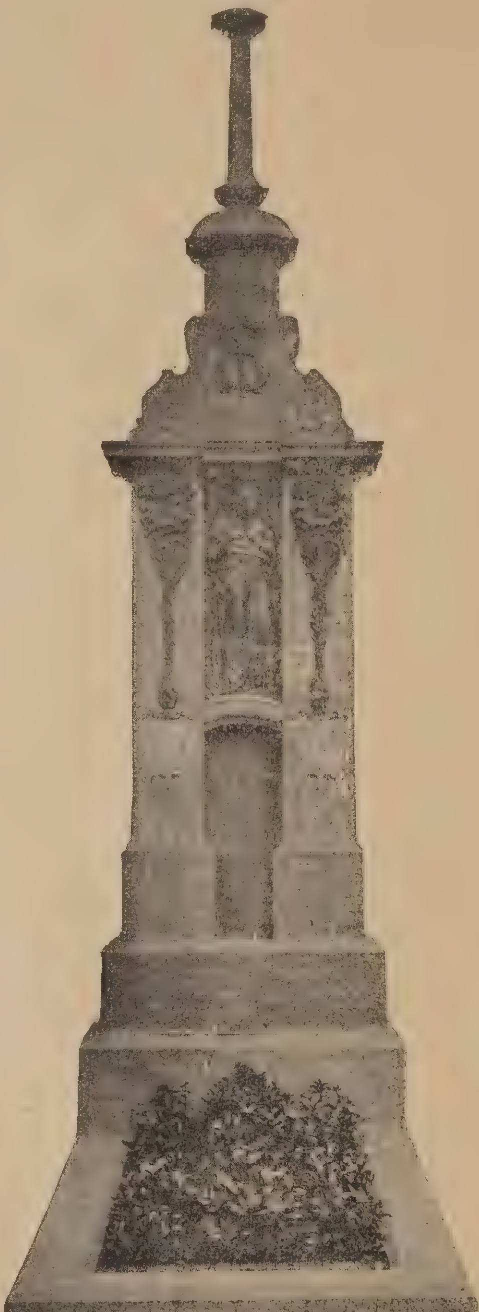
APHORISM FOR THE WEEK.

It is a general law, of singular importance in the present day, a law of simple common-sense, not to decorate things belonging to purposes of active and occupied life. Wherever you can rest, there decorate; where rest is forbidden, so is beauty.—RUSKIN.

Our Plates. GREYFRIARS CHURCH, Aberdeen, is to be pulled down, though this decision has not been arrived at without a great deal of opposition on the part of the University, the Presbytery, the Ecclesiological Society of Aberdeen, Sir George Reid, and Mr Whyte (the architect of the University tower). But, willy-nilly, the Philistines have decided to demolish it; and so goes a fine specimen of Gothic architecture. Particulars of the church will be found on page 156 of our issue for April 3rd last.—Oxford Place Chapel, Leeds, which is situated in an important public position near the Leeds Town Hall, is not an entirely new building, but is a reconstruction of an old square, barn-like structure which had occupied the site for about a century. The work consists of a new front and side elevation, as seen in the perspective view, and a large amount of remodelling in the interior, together with new seating, stained glass windows, and colour decoration. The tower and the remainder of the building to the right have not yet been built, but it is intended to commence this portion of the work in the course of a few months. The chapel is faced with red bricks from Messrs. Woolley's brickyards, with stone dressings, the stone being obtained from the Wroso Hill quarries, near Shipley. Oxford Place Sunday-school took the place of an old school which was previously pulled down. It is situated at the rear of the chapel, and fronts to Oxford Row. The new building was put up prior to the restoration of the chapel. The interior accommodation comprises a series of class rooms and vestries, and a large assembly hall on the first floor, with direct communication with the chapel. These two buildings at Leeds were carried out from the joint designs of Mr. G. F. Danby and William H. Thorp, F.R.I.B.A., both of Leeds.

A Derelict Church in Central London. RATHER more than a year ago the condition of St. Mary's Church, Soho, was pitiable in the extreme. Its ancient nave, built for the use of the Greek colony in 1677, had been destroyed by the London County Council in 1898 as a "dangerous structure." Shapeless and roofless, the nave lay a veritable heap of stones. The lofty chancel, the foundation stone of which was laid in 1872, was in a sad state of dirt and neglect, though its walls were intact. The church has now been restored. £4,568 has already been raised, and the new nave is now built. But a further sum of £2,232 is still required to enable the church to be re-opened free from debt. Contributions should be sent to either of the treasurers to the St. Mary's, Soho, Restoration Fund—Mr. T. F. Blackwell, J.P., 21, Soho Square, W.; the Rev. J. H. Cardwell, St. Anne's Rectory, 28, Soho Square, W.

Leadless Glaze. "A MANUFACTURER," writing to "The Times" upon the proposed new regulations of the Home Office, is of the opinion that if they are insisted upon the "potting trade" of this country will be absolutely ruined. He says: "Most of the leading firms have complied with all the regulations laid down from time to time in the last few years; but there are scores of small and struggling factories, which in the aggregate employ thousands of hands, who cannot afford and have not the means of carrying out all the requirements of the Home Office. My firm is quite willing to place at the disposal of any manufacturer their "leadless glaze" receipt, for which they were awarded a gold medal by the Society of Arts in 1820, but I fear few, if any, would be willing to avail themselves of it; not only because of the extra expense of using same, but the absolute certainty of the impracticability of applying it to their present body of ware; moreover, I have no hesitation in saying if they made the attempt the result would be disastrous. It therefore means that if the Home Office insist upon all potteries using a "leadless glaze" a very large proportion of the small and struggling firms will either have to alter the body of the ware, so as to withstand the very high temperature necessary to properly fuse the hard (leadless) glaze now suggested, or else close their works. The latter, I fear, will be the ultimate result in the majority of cases, as to do what is necessary to accomplish the above means heavy additional expense in adapting existing kilns to this hard firing, besides the extra expense of better and more coal for the longer and harder firing necessary."



MEMORIAL, BROMPTON CEMETERY. H. FULLER CLARK, ARCHITECT. BRONZEWORK MODELLED BY FREDERICK W. POMEROY.

Mr. Birrell on Cathedral Screens. MR. AUGUSTINE BIRRELL expresses himself on a variety of topics. The latest is that of cathedral screens. Describing Cologne Cathedral in the "Century Magazine," he says "that when you have passed through the western doors into the nave you can scarcely restrain your cheers. No miserable partition, no ill-placed organ, mars your view of the splendid proportions of the edifice you have just entered. Your eye runs with joy up the avenue of pillars, past the shadows of the transepts, enters the choir, and reverently beholds the steps of the altar, and is rewarded by the rich hues of the eastern window—and all in a moment of time! In how many of our English cathedrals is the eye robbed of this rich harvest! Too often one enters with a groan instead of with a shout of praise. An open screen of ironwork 12ft. from the ground is all that is required to divide the choir from the body of the church. It should be made a *præmunire* without benefit of clergy to allow any other partition to remain in any cathedral for more than three months after the publication of this number of the 'Century Magazine.'"

A Memorial. THE memorial illustrated on this page has been erected in Brompton Cemetery, and is of plain grey "Alloa" granite, bronze and copper. The bronze lilies at either side of the central panel have scrolls entwined in the stems, on which are inscribed the words "Alpha" and "Omega." The finial is in copper. The granite work was carried out by Messrs. Fenning & Co., of Salters' Hall Court, E.C., and the modelling of the bronzework by Mr. Frederick W. Pomeroy, of Wentworth Studios, Chelsea. Mr. H. Fuller Clark, of John Street, Bedford Row, was the architect.

Woodcroft Castle. THE Old Manor House, called Woodcroft Castle, an historic pile dating from the thirteenth century, stands a short distance on the left (or west) of the main line of the Great Northern Railway, about five miles north of Peterborough. Until recently the castle was in comparative seclusion, being almost entirely hidden from view by the surrounding trees. These have now been removed, and the time-worn structure, with its fine old mullioned windows and its famous round tower, stand fully revealed to the passer-by. The building is attributed to the latter part of the thirteenth century, and the existence of small square trefoiled windows leads one to suppose that the construction took place under foreign supervision. The round tower has, it is supposed, been utilised as a prison, as there was no access thereto from the interior of the castle. Woodcroft is seven miles from Stamford, and about one mile from Helpstone, where John Clare, the peasant poet, lies buried.

An Old London Inn. THE relics of the old coaching days seem fast disappearing in our London streets. Holborn, that once gloried in a wealth of old-time houses and taverns, is now filled with glaring gin palaces and shop premises, on their glass tank ground-floor fronts, all of outrageous design. The announcement is now made that the last of the ancient inns of Holborn, the Black Bull, is to come down. The Black Bull and its neighbour, the Old Bell (now a new erection) claim to date from the middle of the seventeenth century. It is difficult to trace the exact date of the building of either of these hostelries, but both figure in a list of courts, rentes, and inns published in "A New View of London" in 1708. The Black Bull as it stands to-day is but a shadow of its former self. The quaint old galleried building which overlooked the courtyard was some years ago converted into tenements for poor people, which have now been vacated in preparation for the coming demolition. The Black Bull, if not famous in fact, is renowned in fiction. Dickens's readers will remember that it was at the Bull Inn in Holborn that Mrs. Gamp and Betsy Prig nursed Mr. Lewsome—"Nussed together, turn and turn about, one off, one on." How different from the house as the immortal "Sairey" found it, is the Bull of to-day! We should look in vain for the "intricate passages" through which the chambermaid led her to the top of the house. The chamber where the patient lay, we are told, was at the end of a gallery, and looking from the window of this room, which she found "a little dull, but not so bad as it might be," Mrs. Gamp was "glad to see a parapidge, in case of fire, and lots of roofs and chimney-pots to walk upon." The furniture of the apartment was not so much to her liking, and she complained of the easy chair that it was "harder than a brickbadge." It is to be hoped that the sign of the bull pawing imaginary ground over the entrance to the courtyard will be preserved in the Guildhall Museum.

Builders' Notes.

Change of Address.—The testing station of the British Fire Prevention Committee has changed its location from North Bank, Regent's Park, to Westbourne Lodge, 66, Porchester Road, Bayswater, W., to which address communications for the Resident Engineer, should be sent.

A Scaffold Accident resulting in injury to seven men occurred at Birmingham last week. The men were engaged at a high building in Eyre Street, when the structure bearing them suddenly gave way and they were thrown to the ground, a distance of 30ft. Four of them were taken to the hospital in a critical condition, and one died there not long after admittance, his skull having been fractured.

The Building Trade at Chester-le-Street.—Whatever may be the case in other districts, there is no likelihood of any dulness in the building trade around Chester-le Street for the coming season. On three extensive estates dwelling-houses and shops are already in course of erection in Chester-le-Street itself, while at Grange Villa Mr. C. Groves is rapidly enlarging the amount of habitable property. A new Primitive Methodist chapel to cost something like £2,000 is to be commenced with almost immediately at the north end of Chester-le-Street, and a large house to the south of the present Primitive Methodist school. Immediately opposite this a new and enlarged Mechanics' Institute is to be built. The old hostelry known as the Lambton Arms is also to be rebuilt, and the Joiners' Arms is to a certain extent be to reconstructed. An improved theatre and a workmen's club are also contemplated. Further afield a new Co-operative Society is to be erected at Birtley.

Masters and Men.

The Norwich painters belonging to the Union in accordance with a month's notice to their employers, are now out on strike for an increase of wages, from 6d. to 7½*d.* per hour, and alterations to the existing working laws.

The Harrogate Plasterers have Struck against a proposed reduction of wages. When the building trade was remarkably brisk a year or two ago, the wages reached 10½d. per hour, and the masters now propose tc reduce them to 9½d. per hour, a similar rate being paid in other Yorkshire towns.

The Strike of Cement Workers at Stroud is at an end, an amicable arrangement having been come to. Parts of both sections of the factories at Frindsbury have been reopened, and about 200 men have resumed work. The rest of the hands required are to be taken on gradually until the whole of the works are again in full swing, but a month will probably elapse before this has been accomplished.

The Arbroath Joiners have Struck. It appears that the dispute arose in connection with the signing of the by-laws. It is customary for the societies connected with the joiners to give the employers three months' notice regarding the constitution of their rules, and during that time the masters are expected to sign their approval to the same. The specified time having expired, the men accordingly resolved not to resume work. Between thirty and forty men are idle.

Labour in the Colonies.—The April circulars of the Emigrants' Information Office and the new annual editions of the penny handbooks show the present prospects of emigration. This is the best season of the year for emigration to Canada. There is a fair demand for general labourers, and for certain mechanics, such as carpenters, blacksmiths, and iron and steel workers. In New South Wales, at Lithgow, there is a demand for carpenters and painters. There is a demand in parts of the colony for men in the building trades, especially plumbers. In Victoria there is practically no demand for more mechanics or labourers, unless they are specially skilled, and bring a little money with them. In South Australia and Tasmania the local supply of labour is mostly sufficient. Owing to drought and scarcity of employment in Queensland, emigrants are not recommended to go there at present unless they receive nominated passages, or take a little money with them. The report of the Government Labour Bureau in Western Australia for 1900 states that, generally speaking, there has been full employment for all classes of workmen throughout the year. Building operations have been brisk, and carpenters, masons, plasterers, &c., have been in demand at Fremantle. Timber-workers have also been wanted in parts. Unskilled labour was better employed than in the year before, and first-class labourers found no difficulty in obtaining regular employment at good wages. The last reports show that there was plenty of work in New Zealand. In Auckland there is good employment for bricklayers, carpenters, and general labourers; a fair demand for plasterers, painters, and engineers. In Taranaki there is a great demand for competent general labourers for road-work, &c., and the sawmills and building trades are very busy. In nearly all other parts also of New Zealand, except at Christchurch, the building trades have been very busy; and at Dunedin carpenters have been wanted. In the engineering trades all hands seem fully employed, but there is no special demand for extra men.

Correspondence.

Loads on Floors.

To the Editor of The Builders' Journal.

Chorley, Lancs.

Sir,—Having read the correspondence relative to "Load on Girders" in your issues of January 30th, February 20th and March 13th, I should like to make a few remarks concerning that portion which refers to loads on floors.

In your issue for February 20th, "J. D." informs us that "*a* text-book" gives 1¼ cwt. per sq. ft. distributed load as a proper allowance for a living-room floor, including weight of floor itself. Professor Adams states, in reply, that this text-book is not reliable, and cites "Molesworth" in his support, and also states that a "dense crowd averages 120lb. per sq. ft."

It is assumed, I take it, that in "J. D.'s" text-book the floor is an ordinary wood floor of joists and boarding with a plaster ceiling underneath. This floor and ceiling would weigh from 18lb. to 22lb. per sq. ft. (depending, of course, on size and spacing of joists, &c.); say, 20lb., leaving 120lb. for the live load, on the assumption of a total allowance of 11 cwt. per sq. ft.

I do not know whose text-book "J. D." refers to, but from another I am informed that "the engineers of the Chelsea bridge *packed picked* men (italics not mine) upon the platform of a weigh-bridge, with a result of 84lb. per sq. ft."; that "Mr. Nash, architect of Buckingham Palace, experimenting with reference to fireproof floors for that building, wedged men together as closely as they could possibly stand upon an area of 20ft. diam., the last man being lowered down from above among the others—result 120lb. per sq. ft." In another place it states: "The greatest load that can come upon an ordinary bridge is a dense crowd of people, and the French engineers estimate this at 41lb. per sq. ft. of platform"; that though "this is certainly as great as can well occur under ordinary circumstances, it may be considerably exceeded," &c., and advises that, to include for the crowd being in motion, &c., an allowance be made of not less than 100lb. per sq. ft., with a factor of safety of not less than 3 added to the weight of the bridge itself.

Now, is it really necessary to assume, or provide for, a dense crowd for an ordinary living-room floor? It seems to me not necessary. Does not the greatest load that is at all likely to come upon it occur during an auction, in which case it surely would not be more than "packed" with people (assuming all furniture removed), giving a load of 84lb. per sq. ft.; add to this, say, 28lb. per sq. ft. for the crowd in motion, making a total of 1 cwt. for live-load. We are still under 1¼ cwt. for the total load.

I think, therefore, that "J. D.'s" text-book is not proved to be unreliable—rather the reverse It is, no doubt, well to be on the safe side; but having reached that, there is surely no need for going further, especially where economy is an important factor.—Yours truly,

A. C.

Sir,—The text-book referred to by "J. D.," which says "1¼ cwt. per sq. ft., including weight of floor for distributed load," probably takes the figure from Hurst's architectural handbook, which was written before concrete floors were in common use, or the dead and live loads would have been dissociated. The weight of material alone in a concrete floor usually exceeds ½ cwt. per sq. ft., and when the strength of any floor is calculated it is usual to add its weight to whatever allowance per sq. ft. is taken for the external load. In the case of a common wood floor with single joists it is of little consequence either way, as its own weight is so small. In my "Handbook for Mechanical Engineers" I give the results of many experiments on the weight of crowds, varying from 35¼lb. per sq. ft. for people spaced as troops on the march to 147·7lb. quoted by B. B. Stoney in "Stresses." But the danger is not so much in the actual load as the increased stresses brought on by dancing, wrestling, moving heavy weights, &c. To provide for only 1 cwt. per sq. ft. total load and a factor of safety of 3 would be running a risk that might involve the attendance of a coroner later on.

Take an actual case. I have a room at home in which the floor joists are 3in. by 4in., 14½in. centre to centre, with a span reduced by sleeper walls to 7ft. An ordinary person walking across the room hurriedly shakes a bookcase against one of the walls somewhat severely, and dancing is quite out of the question. Calculation by the formula $\frac{c\,b\,d^2}{L}$ gives $\frac{3 \cdot 5 \times 3 \times 4^2}{7} = 24$ cwts. breaking weight in centre on each joist, or 48 cwt. distributed, and a factor of safety of 3 would make the safe load on each joist 16 cwts. distributed over 7ft. span, or $\frac{16}{7} = 2 \cdot 3$ cwt. per ft. run. The centre distance being 14½in., the equivalent load per ft. sup. is $\frac{12}{14\frac{1}{2}} \times 2 \cdot 3 = 1 \cdot 9$ cwt., or nearly double the amount that "A. C." would provide for, and yet the floor is too weak for ordinary uses. The common rule for such joists would be $\frac{7}{2} + 2 = 5\frac{1}{2}$ for depth, and $\frac{5\frac{1}{2}}{2} = 2\frac{3}{4}$ for thickness, or the nearest usual scantling of at least equal strength, say 7in. × 2in.—Yours truly,

HENRY ADAMS.

New Patents.

The following specifications were published on Saturday last, and are open to opposition until May 27th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—5,366, Knöfler, incandescent bodies for gas-lighting. 6,030, Farley, bearings for shafts applicable to air valves or ventilators. 6,996, Chorlton & Wentworth, rotary cutting, planing, and shaping appliances for woodworking machinery. 7,403, Graham, window fastener. 7,795, Calderbank, electric light fittings. 8,247, Grove, securing handles to spindles of locks and latches. 9,113, Thomson, portable machine for cutting mortises for locks. 9,215, Isler & Broadhurst, apparatus for earth-boring and pile-driving. 9,620, Smith, lavatory fittings. 13,227, Rech, band-saw machines. 16,564, Smith & United Alkali Co., Ltd., device for disinfecting water-supply. 21,019, Ketchum & Schwoob, wrenches. 22,280, Jones & Jones, night latches and draw-back locks. 22,417, Ford, gutters for use in stables and similar buildings. 22,625, Pearce, folding dressing-boxes for swimming baths. 23,850, Brookes (*Incandescent Gas Light Co.*), apparatus for incandescent gas-lighting.

1901.—1,397, Thompson, automatic flushing cistern. 1,398, Thompson, flushing cistern. 1,784, Jensen, means for repairing wooden stairs. 2,076, Ramsey, Burns & Haywood, fasteners for window sashes. 2,578, Glover, joiners' and similar cramps. 3,102, Baxter, toggles for stone-breaking, ore-crushing, and other machines. 3,296, Boult (*Soc. Lumière Boule*), burners for incandescent gas-lighting. 3,538, Napier, flushing tanks for water-closets. 3,553, Milnes, heat radiator. 3,947, Mainzer, mosaics.

Engineering Notes.

Visit of Glasgow Engineers to London.—For the last four years the Glasgow University Engineering Society has been accustomed each spring to visit one of the large centres of industry in this country. This year they visit London. The visit extends from April 16th to 20th.

The Death is announced of Mr. George Farren, M.I.C.E., F.S.S., of Carnarvon. At one time he was engaged under Messrs. Freeman & Son, and subsequently settled in Carnarvonshire, where, as a quarry-owner, he constructed, in connection with the Trevor Works, a complete village, with schools, chapels and a church.

The Death is announced of Mr. J. J. Tylor.—He died at his villa at Cap d'Ail, near Monaco, on April 5th. Though by profession an engineer, he had a well-merited reputation among specialists in Egyptian archæology. His series of enlarged photographs, completed by hand, of the "Wall Drawings and Monuments of El Kab" (1895–1900) presents a near approach to absolute reproduction of these important documents of ancient history.

Engineer's Heavy Failure.—A meeting was held last week of the creditors of Herbert Alexander, engineer, of Queen's Engineering Works, Leeds, and 159, Cannon Street, London. The statement of affairs showed gross liabilities £98,570, of which £64,857 is expected to rank for dividend. Assets were estimated at £38,442. The alleged cause of bankruptcy was the failure of a firm of foreign bankers.

The Blackman Ventilating Company, Limited, have acquired the business of Mr. James Keith, C.E., heating engineer (with departments in gas and hydraulic work), carried on at London and Arbroath. This union of two large businesses in ventilating and heating respectively rests largely on the essential dependence of these two branches upon each other for perfect development and successful use. Under the new name of **James Keith & Blackman Company, Limited,** the company has within itself the means of rapid first-hand production of all the best modern appliances for warming and ventilating.

The Andrew Carnegie Research Scholarship.—A research scholarship or scholarships, of such value as may appear expedient to the Council of the Iron and Steel Institute from time to time, founded by Mr. Andrew Carnegie (vice-president), who has presented to the Iron and Steel Institute certain debenture bonds for the purpose, will be awarded annually, irrespective of sex or nationality, on the recommendation of the Council of the Institute. Candidates, who must be under thirty-five years of age, must apply, on a special form, before the end of April to the Secretary of the Institute, at 28, Victoria Street, S.W. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students who have passed through a college curriculum, or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry.

A Municipal Hot-water Supply.—A municipal hot-water pipe which supplies all the buildings in the town with hot water for heating purposes has been devised for the city of Chorbusco, Indiana. Large mains have been laid about 3ft. below the ground, and these are protected by many layers of corrugated paper and wood. Specially constructed boilers have been provided at the central station, and from these hot water is sent forth to all parts of the city. When the housewife desires her rooms to be heated, all she has to do is to turn on the tap, when the water flows through the pipes and radiates in a continuous stream, and in a very short time brings the atmosphere of the room up to the desired temperature. It is said that the system of regulation is so good that the heat can be controlled simply by reducing or increasing the flow of water as the occasion may require. Eventually the water finds its way back to the central station, where it is re-heated.

Contract for Widening Byker Bridge, Newcastle.—The Teesside Bridge and Engineering Company, Limited, of Middlesbrough, have secured the contract for the widening of Byker Bridge, Newcastle-on-Tyne. Eight firms sent in designs, and that of Teesside was considered the best and least expensive. Their tender amounts to £22,280. The Byker Bridge, which is of brick, is the property of the Newcastle Corporation, and connects Byker in the east to Newcastle by spanning the valley of the Ouseburn. The present structure, which is 1,280ft. long, has one roadway and one footpath, the total width being 32ft. 6in., not sufficient to accommodate two lines of tram rails and ensure safe traffic. It has been decided to increase the width of the bridge to 52ft. 6in., there being two footpaths 10ft. wide each, and the road 32ft. 6in. The above firm are to make provision for keeping the bridge open for foot traffic during the alterations with proper precautions for the safety of the public.

The Pier at St. Anne's, Lancashire.—The pier at St. Anne's, near Preston, is to be widened by Messrs. Garlick & Sykes, engineers, of Blackpool and Preston. The present width of the deck is 18ft., and the scheme provides for a widening to 34ft. The area of the pier-head is also to be extended to more than three times its present size. On the north-west is to be the pavilion, while on the opposite side will be an enclosure, surrounded by shops, refreshment rooms, &c., and furnished with a band stand. The arrangement is similar in its main lines to that adopted in the design of the North Pier at Blackpool. Before the work can be proceeded with it will be necessary to obtain a provisional order, and this cannot be applied for until November, when the plans will be deposited. It is therefore apparent that nothing can be done in time for the season of 1902.

East London Railway.—The Whitechapel and Bow Railway, which will connect the Tilbury and Southend Company's line with the underground railway systems of London, is making good progress. The erection of the new bridge over which the G.E.R. trains will pass to Fenchurch Street from Bow is now in hand, while the model dwellings which the company had to erect to accommodate the people displaced are completed. Work on the new stations at Stepney Green, Burdett Road, and Wellington Road is now proceeding and making rapid headway. Some idea of the magnitude of the work can be gauged by the fact that the construction of the line, which is only two miles long, will necessitate the use of 30,000 tons of cement, 13,000,000 bricks, 12,000 tons of steelwork, while no less than half a million tons of earth have to be excavated.

MANSFIELD NEW PUBLIC HALL.

THE Victoria Hall has just been erected by the Mansfield Brewery Company on a prominent position at the top of Leeming Street. The materials are red bricks, relieved by stone dressings. The chief hall measures 78ft. by 39ft. and 28ft. high, providing accommodation with balcony for upwards of 800 people. It is lighted by six semicircular windows on the north side, and a seventh in the gable end overlooking Leeming Street. A stage, fitted with appliances for theatrical performances and provision for an orchestra, occupies one end of the room, whilst four dressing rooms or retiring rooms with the necessary conveniences are to be found at the rear. The decorations of the hall are of an ornate character. The ceiling has been divided into seven bays by beams painted pale sage green, the plaster being Durescoed a cream tint. Inside each bay a decorative panel, worked in buff and grey, shaded and outlined with reddish brown, and containing some eminent name in music, poetry, or the drama, is painted. Over the stage is a large scroll design executed in grey, and shaded terra cotta, the walls being Durescoed in the same colour. The dado and woodwork are covered with a shade of pale green. The entrances are wide and lofty. Under the hall is a supper or dining room, which will also be used for smoking concerts, meetings, &c. The architects are Messrs. Vallence & Westwick, of Mansfield; the builders Messrs. J. Hutchinson & Sons, Nottingham; whilst the decorating has been done by Mr. C. E. Greenwood, Mansfield.

Views & Reviews.

SPECIFICATIONS.*

Few architects enjoy the trouble and mental drudgery connected with the preparation of an ordinary specification. At the present time there is an increasing tendency to call upon the quantity surveyor to draft the specification in addition to the bills of quantities, and, provided that the architect has supplied the requisite data, such a course is generally satisfactory. On the other hand, many architects prefer to draw up their own specifications; for having prepared the drawings, and being about to superintend the work, they naturally consider that they can best describe their own particular requirements. In either case, it must be remembered that such a document necessitates the most careful consideration, for it possesses considerable legal importance in a building contract. A well-written specification should therefore clearly and concisely describe the local conditions under which the work is to be carried out, whilst at the same time supplying detailed particulars of the several materials and workmanship required, so that the builder may be afforded every reasonable facility in properly interpreting the drawings, and by this means clothe in suitable and concrete form the architect's original conception.

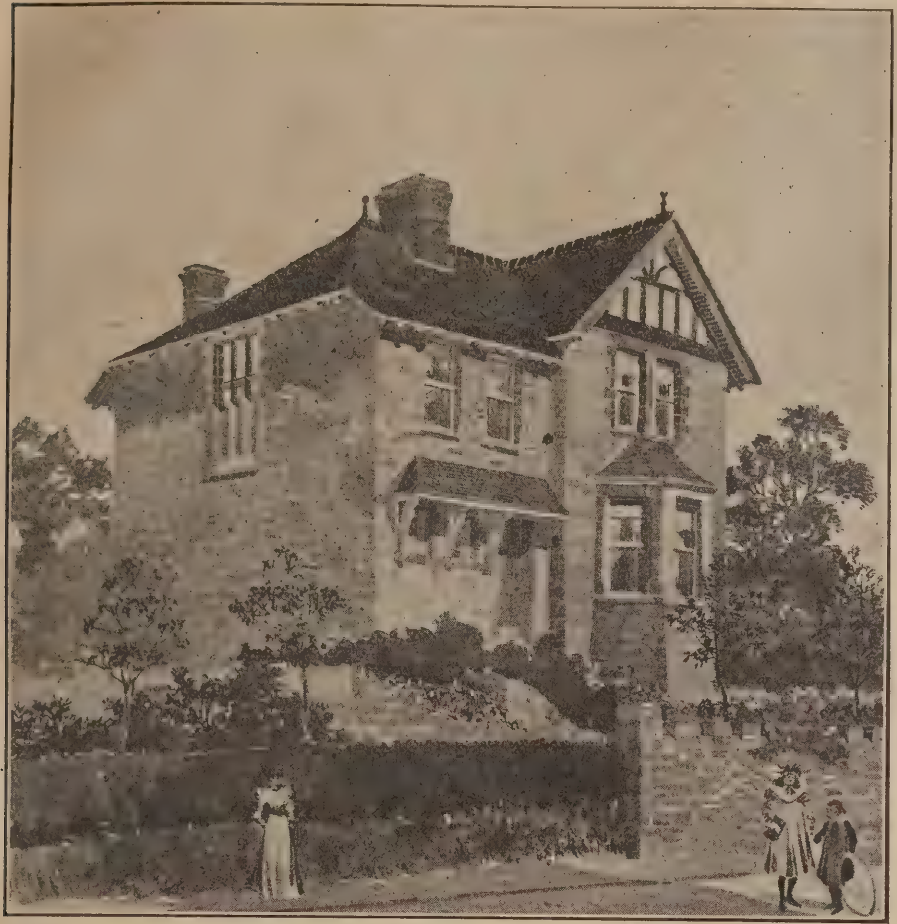
Mr. Leaning's exhaustive work on building specifications cannot but prove to be of the greatest assistance to the specification writer, whether architect or quantity surveyor, and we congratulate the author on the admirable manner in which he has dealt with the subject. This handsome volume contains upwards of 600 pages and 140 illustrations. The broad principles underlying the preparation of a well-considered specification are in the first place succinctly set forth, and the suggested order in which the various items of each trade should be taken is conveniently given in tabular form. This summary will be found extremely useful for comparison, and also for securing a systematic and uniform order of procedure.

A valuable feature of the work consists of a complete specification for a large mansion, including stables, conservatory, and boundary walls. It comprises 714 clauses, and provides a very good model for purposes of general reference, although in some few matters of detail it scarcely describes the most modern or approved methods of construction. When iron drains and fittings are used in high-class work it is usual to provide cast-iron access pipes or junction boxes, fitted with proper covers and fastenings, to all inspection or intercepting chambers, instead of the ordinary iron channels or pipes mentioned here. In clause 87 it is laid down that no four courses of brickwork with their joints shall rise more than 12in. high. Generally it is preferable to specify that every four courses of brickwork are to gauge in height not more than 1in. in addition to the four courses if laid dry. The maximum thickness of joints permissible in the brickwork is thus closely defined, and is quite independent of the thickness of bricks used, for the latter may vary from 2½in. to nearly 3in. thick, according to the particular yard or locality from which they are obtained. Breeze-concrete lintels cast in moulds, and having one or more rolled steel joists of suitable section embedded in them are now superseding fir lintels in large or important buildings; but only the well-known clause relating to the provision of wood lintels to all openings finds a place in this specification. An alternative clause giving particulars of the more durable and fire-resisting variety would have been appreciated. Taken as a whole, however, this typical specification is full, comprehensive, well-balanced, convenient in arrangement, and accurate.

In addition to the representative specification just noticed, a series of clauses are given which apply more particularly to works of special character. These sub-sections include sewers, cofferdams, camp-shedding, concrete buildings, alterations, additions, and repairs; church restoration and underpinning, schools, churches, warehouses and manufactories, public baths, underground conveniences, shop-fronts, public-houses, cold storage, heating of buildings, electric

---

* "Building Specifications." By John Leaning, F.S.I. London: B. T. Batsford, 94, High Holborn. Price 18s. nett.



"INGLENEUK," DOWNEND, NEAR BRISTOL. LA TROBE & WESTON, ARCHITECTS.

lighting, roads and paths. It is strange that there is no sub-section containing some of the clauses peculiar to hospital construction (such as the provision of rounded angles to plastering, skirtings, door and window finishings, &c.), considering the importance of this class of buildings.

The author's remarks on building contracts are well worth careful perusal, and in this connection the general conditions of contract as revised by the Royal Institute of British Architects are quoted in their entirety, together with detailed examples relating to the provision of separate contracts for special materials such as structural ironwork; the manufacture, delivery, and fixing of terra-cotta, faïence, &c.

The practical character of the work is considerably enhanced by the large amount of information which is given concerning the different trades and methods of executing work, and includes some important notes on foundations, drains, paving, qualities and descriptions of building stones, shippers' marks on timber, fire-resisting materials, &c.

Mr. Leaning's book can be thoroughly recommended to all who desire to become conversant with the art of specification writing, and also to those who require a reliable text-book which may be consulted in any case of difficulty or doubt.

T. E. C.

"Ingleneuk," Downend, near Bristol.

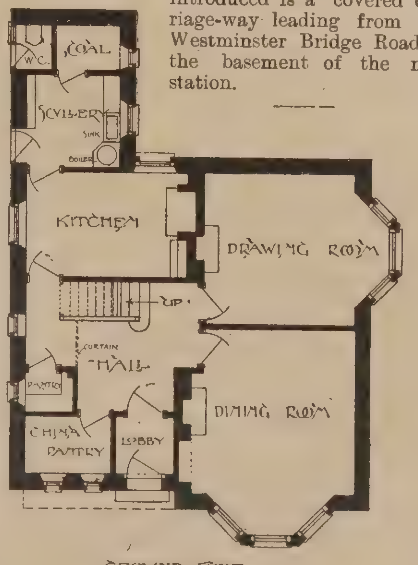
THIS house stands on a quarter-acre plot on a suburban estate which has recently been laid out. The object aimed at was to secure a convenient and pleasing house at about the same cost as that of the usual speculative house. The walls are built of the local red-grey Pennant stone, with Bath stone dressings and tiled roofs. The woodwork is painted a sage-green colour. A feature of the plan is the way in which all the flues are gathered into a central stack, thus minimising the loss of heat. The kitchen premises are screened off by a curtain, and as one bedroom is entered from the half-space on the stairs a picturesque effect both in the hall and externally is obtained. The architects were Messrs. La Trobe & Weston, of Bristol.

A NEW NECROPOLIS STATION.

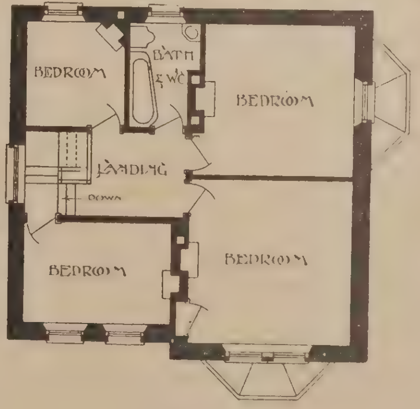
FOR a long time past the London Necropolis Company have found their station at Waterloo totally inadequate, and it was decided to erect a new station. This is now rapidly nearing completion, and when finished will have cost about £100,000. It occupies a new site, a little further down the line than the old premises. The new station is built on most elaborate lines, elaborate arrangements being made for the expedition of business and the comfort of mourners. There will be two separate platforms and a private chapel, and suitable provision has been made in the shape of comfortable waiting-rooms. There are several mortuaries of different sizes, and electric lifts from the road level to the departure platform. Among other new features introduced is a covered carriage-way leading from the Westminster Bridge Road to the basement of the new station.

A NEW INFECTIOUS DISEASES HOSPITAL FOR CHORLEY.

THE New Chorley Joint Infectious Diseases Hospital has been erected on a site of about six acres at Heath Charnock. Messrs. Jolly & Buckley, of Chorley, were the architects, and the contractor was Mr. Robert Brownley, of Chorley, with Mr. Leonard Fairclough, of Adlington, as sub-contractor for the stonework, Messrs. J. Fairclough & Sons, of Chorley, sub-contractors for the slating and plastering, and the executors of Mr. Heald for the plumbing, the painting and the glazing. The cost of the work (including furnishing and sewerage) is £17,000. The hospital consists of five blocks of buildings, namely, the administrative block, the diphtheria block, the typhoid fever block, the scarlet fever block, and the working block. To the right of the entrance gate is the administrative block from the vestibule of which opens a waiting-room for the friends of patients. From the vestibule a spacious hall is entered, from which lead off the matron's sitting room, a sitting-room for the nurses, doctors' dispensary and sitting-room, and the kitchen accommodation. In the hall is the telephone switch board, which will enable the matron to communicate with, and to receive communications from, all parts of the district and the nurses' rooms in the several pavilions. From the hall a staircase gives access to the upper floors. On the first floor are eight bedrooms for nurses and probationers, and the matron's bedroom, which is provided with electric communication with the servants. A bathroom, a linen store (the contents aired by hot water pipes), and the usual offices complete the accommodation. On the second floor are bedrooms for the domestic servants, with, on the landing, a large storage tank of water ready for use in the event of fire or any other emergency. The windows, with irregular panes, admit plenty of light, and escape a monotonous uniformity; the walls are tastefully, yet not too ornately coloured. Totally separate from the administrative quarters, and ranging in blocks from north to south, are the hospital buildings proper. Each block has a glass verandah, covering a plainly-tiled approach from the road leading to the pavilion. Further west is the diphtheria pavilion. Here are provided two wards. From a room between the nurses can survey all that goes forward in the wards, and receive through a special window the food sent from the kitchen of the administrative block. Two other wards in the diphtheria pavilion are respectively for miscellaneous cases and for cases which are undiagnosed; and the same arrangement in regard to the nurses exists for these wards, and in the other pavilions also. These other pavilions are the typhoid pavilion and the scarlet fever pavilion. Each consists of two wards—one for males and the other for females. The ward floors are of wood blocks. In the typhoid and scarlet fever pavilions provision is also made for the immediate ejection from the building of soiled linen, bound for the disinfector near; and the wards are warmed by Shorland's patent stoves. The last block—the working block—contains the disinfector house, the laundry, the mortuary, the stables, and the ambulance house.



GROUND FLOOR



FIRST FLOOR

"INGLENEUK," DOWNEND, NEAR BRISTOL. LA TROBE & WESTON, ARCHITECTS.

Keystones.

A Statue of the late Queen is proposed to be erected at Harwich.

A Bronze Statue of Sir W. T. Lewis, Bart., has been erected in the grounds of the Merthyr Hospital. The statue, sculptured by Mr. Brock, R.A., is life size, and is placed upon a granite pedestal, the work of erection having been carried out by Mr. Evan Jones, of Dowlais. From the foundation to the crown of the head the statue is 17ft. in height.

A New Police Station and Branch Library Premises in Dewsbury Road, Leeds, are to be erected from designs of Messrs. Bedford and Kitson, at the estimated cost of £12,050 The plans had been selected by the assessor in a competition open to Leeds architects. Application is also to be made to the Local Government Board for sanction to the borrowing of £9,059, the estimated cost of branch premises at Stocks Hill, Armley.

An Ancient Cross at Aldford, near Chester, which stands in the churchyard, has been restored in memory of the late Duke of Westminster. The restored cross stands on the original worn stone steps, and consists of a shaft about 11ft. high. The material used is Runcorn stone. The design has been copied from the 15th-century cross in Betterley churchyard. Mr. F. G. Sewell, of Chester, has carried out the work.

New Cattle Market for Truro.—A Local Government Board enquiry was held recently into an application by the Truro Corporation for sanction to borrow £5,400 for the entire remodelling of the cattle market. The plans have been prepared by the surveyor and engineer, Mr. M. Lea. The new market by the addition of a new piece of land will cover 6,588 square yards. The present variation of levels will be altered, so that the new market will be level. Accommodation will be provided for 3,200 sheep, 500 pigs, and 575 beasts, which is nearly double that of the present market.

A new Cottage Hospital at St. Andrews is to be erected on a site at the east corner of Abbey Park, on ground extending to about three-quarters of an acre. On the ground floor will be three wards, containing four, two, and four beds respectively. There is also a large and well-lighted surgery, and a sitting-room for the matron and staff, and there is also a spacious and well-lighted staircase. On the floor of the central block there is a female ward containing two beds, and a children's ward with six cots. There are also four bedrooms for the nursing staff and servants. The kitchen accommodation is in a separate wing to the back. The architect is Mr. Charles F. Anderson, of St. Andrews.

The Glasgow Architectural Association recently visited Sauchie and Clackmannan Towers, the former through the courtesy of the Earl of Mansfield, and the latter by permission of the Marquis of Zetland. The leader at Clackmannan Tower was Mr. A. F. Balfour Paul, who gave an exhaustive and interesting description of the old castle, and recalled all its historical associations. The party then drove to Sauchie Tower, where Mr. John Watson acted as leader, and exhibited measured drawings which he prepared many years ago before the topmost portion of the tower was demolished. The castle and the fine old cottages adjoining were examined and described.

A Municipal School of Cookery.—A Local Government Board enquiry was held recently into the application of the Newcastle Corporation for sanction to borrow £10,000 for the purpose of erecting a new school of cookery in Northumberland Road. The Northern Counties School of Cookery and Domestic Economy has been in existence about seven years. It was first commenced by the Newcastle City Council, who were afterwards joined by the Northumberland County Council. It is now proposed to build a new school, on a site belonging to the Magdalene Hospital Trustees (the Newcastle Corporation). It was at first thought that £6,000 would suffice for the building, but after plans had been chosen it was found that £8,000 would be required. The building will last fifty years. Mr. J. W. Dyson is the architect.

Mr. Eden Upton Eddis, the well-known portrait painter, died last week.

The Camberwell Infirmary, in Brunswick Square, is to be extended and completed from plans by Mr. Edwin T. Hall, F.R.I.B.A., of 57, Moorgate Street, E.C.

Mr. H. Percy Monckton, F.R.I.B.A., 32, Walbrook, is the architect for the erection of an isolation hospital and administrative block by the Wrotham Urban District Council.

An Opening for an Architect.—The town of Narberth and the large neighbourhood surrounding the town is at present without an architect, the late architect, Mr. J. M. Thomas, having left no one to succeed him.

Marble Quarries in Alaska have just been discovered, and are said to be almost as valuable as the gold mines there. The quarries are in the southern part of the territory, and the marble is said to be of finer quality and more beautiful than any now produced in the United States, and fully equal to Italian marble.

Two pupils of Mr. J. M. Boekbinder, decorator, of 11, Pratt Street, Camden Town, N.W., who are studying modelling at his establishment, gained a £10 prize each in a competitive exhibition of work under the L.C.C. held at the Northampton Institute recently. The pupils, who are both young lads—one aged sixteen and the other fifteen years—attend the Northampton Institute by Mr. Boekbinder's advice.

The Hearts of Oak Benefit Society have purchased for £36,000 freeholds in Euston Road and Grafton Place as a site for new offices. It has been decided that the leases of a third of the premises shall be purchased for the erection forthwith of suitable offices, for the best designs for which it has been decided to offer premiums of £100, £75, and £50. The cost is not to exceed £55,000.

A Torquay Memorial.—The memorial to the late Mr. Richard Mallock, of Cockington Court, and formerly M.P. for the Torquay Division, is to take the form of a clock tower to be erected on the Strand, Torquay, opposite the Queen's Hotel, and the clock is to have three illuminated dials facing the roads converging there. Competitive designs have been called for, and have to be sent in this month. Mr. James Hine, F.R.I.B.A., of Plymouth, has been appointed assessor.

New Public Wash-houses at Lochee have been opened. The cost of erecting and equipping the buildings has been about £2,800. The main building is 70ft. long by 35ft. broad, and contains twenty-two washing stalls, each with all the latest appliances, consisting of two washing tubs, clothes wringer, boiling tub, and drying horse. The contractors were as follow: Mason work, Mr. James Powrie; joiner work, Mr. John Morrison; slater work, Messrs. Laburn & Son; iron work, Messrs. Nicoll & Jack; plumber work, Messrs. A. L. Peacock & Co.; plasterer work, Messrs. Reoch & Kilgour; painter work, Mr. Arkinson.

Mr. Henry Holtom, a former mayor of Dewsbury, died recently at his native town of Stratford-on-Avon at the age of sixty-four years. An architect and surveyor by profession, he went to Halifax, and then to Dewsbury, and in succession had for partners Mr. W. Bulmer, Mr. Wreghitt Connon, and Mr. G. A Fox. He designed and erected numerous public buildings, including town halls, a free library, central co-operative stores, and board schools. He was placed on the commission of the peace for Dewsbury, and on removing to Stratford soon took a leading position, being elected to the Council and made a county justice.

A New Primitive Methodist Church at Hasland has been erected from designs by Mr. W. Cecil Jackson, M.S.A., architect, of Chesterfield—except for the building of the tower, which has been deferred for a time. The general arrangement internally consists of a large vestibule and chapel, together with two transepts, choir, and minister's vestry; also a separate portion for choir accommodation. The internal fittings are all of pitch pine, the windows being fitted with stained glass. The roof is an open-timber one. The rostrum is in pitch pine. The accommodation of the building is 400, and the total cost, including land, about £3,000.

Mr. George Wragge, whose works are at Manchester, has removed his London premises from 22, Surrey Street, Strand, to 211, Shaftesbury Avenue, W., where he exhibits in a ground-floor show-room all kinds of stained glass, leaded glass, repoussé and other metal work.

Dr. John Sykes, M.D., F.R.C.P., died at Doncaster recently. Although a medical man of some eminence in his profession, he was chiefly distinguished for antiquarian research, and was for many years a Fellow of the Society of Antiquaries.

The English Archæological Society at Rome was opened last week at the Odescalchi Palace. The establishment of the school is due to the initiative of Professor Pelham, of Oxford University, and its object is to interest the English Universities in the study of archæology.

Hindley District Council Offices Competition.—The first premium in this competition has been awarded to Messrs. Heaton, Ralph & Heaton, architects, of Wigan. The cost of the buildings will be about £7,000. The competitors numbered between seventy and eighty.

New Schools for Greenwich.—The foundation stone of the new schools for children chargeable to the Greenwich Board of Guardians, on a site purchased by the board at Sidcup, was laid last week. The cost of site and buildings is approximately £120,000. Accommodation is provided for 524 children.

A Stained Glass Window has been erected as a memorial to the late Earl of Londesborough by the tenantry of the Seamer estates in St. Martin's Church, Seamer, in the south aisle of the church, just above the pulpit. The window is of three lights, the centre representing the Transfiguration, whilst the side-lights bear the figures of the Apostles and holy women. Underneath the central figure is the coronet and coat-of-arms of the Londesborough family. The lights on either side of this are allegorical of Christ feeding the hungry and clothing the naked. The window, which has cost £125, was designed by Messrs. Burlison & Grylls, of London.

Baptist Schools, Histon, Cambs.—The foundation stone of these schools was laid recently. The school is divided off into a number of class-rooms by means of divided partitions, which, when thrown back, make one large hall. Two other large senior class-rooms are provided; also infants' room, kitchen, class-rooms for boys and girls, with the usual offices. The building is of nave and aisle arrangement, the aisles dividing off into class-rooms, with timber columns and arches of quaint design, carrying clerestory. The whole of the internal joinery is to be stained transparent olive green and varnished. The external facing is of red brick with bath-stone dressings, and the roof is of green slates. The contract is let to Mr. H. Feast, builder, Haddenham, Cambridge, and amounts to £1,852. The architects' estimate was £1,875. The architects of the schools, and also of the church recently completed, are Messrs. George Baines, F.R.I.B.A., and Reginald Palmer Baines, of 5, Clement's Inn, Strand, W.C.

Dunfermline Baths Completion.—It having been found that the cost of the competitive designs for the new baths and gymnasium to be erected at Dunfermline exceeded Mr. Carnegie's original offer of £20,000 the committee in charge of the undertaking communicated the estimates to Mr. Carnegie. Mr. Carnegie has now intimated that he agrees to increase the amount offered originally for the construction and equipment of the proposed buildings so that the committee may be free to choose the design which they think most suitable, but that he relies on the committee satisfying themselves that the accommodation to be provided, while ample, should not be in excess of the probable future requirements of the town, and that there should be no expenditure on needless display. The committee have invited Mr. Hippolyte J. Blanc, A.R.S.A., architect, to meet them at an early date, Mr. Blanc's design having thus apparently been accepted. The prizes offered for the designs have been awarded as follows: 1st (50 guineas), Andrew Muirhead, Dunfermline; 2nd (30 guineas), David Barclay, Glasgow; 3rd (20 guineas), James T. Scobie, Dunfermline. The new baths and gymnasium are to be erected in Pilmuir Street, on a site acquired by the town at a cost of £4,000.

New Companies.

W. Rowe & Son, Limited.

Registered March 25th to carry on the business of plumbers, ironmongers, brassfounders, ironfounders, engineers, &c. Capital £3,000 in 550 ordinary shares of £5 each and 250 deferred shares of £1 each. W. T. F. Rowe is sole director till the subscribers appoint a board.

T. C. Williams & Sons, Limited.

Registered March 22nd to acquire the business carried on by W. W. Williams, at Reading, as T. C. Williams & Sons, and to carry on the business of manufacturers, ironmongers, ironfounders, heating and ventilating engineers, &c. Capital £20,000 in £1 shares (4,000 preference). The first directors are W. W. Williams (chairman), A. S. Williams, W. G. Millar, W. Haynes, and C. A. Rollason.

Neal & Company, Limited.

Registered March 23rd to acquire the business carried on by J. F. Neal at Heather, Leicestershire, and elsewhere, and to carry on the business of red brick, tile, and terra-cotta manufacturers, miners, coal and iron masters, chemical manufacturers, &c. Capital £25,000 in £10 shares. The first directors are J. F. Neal, N. Joyce and J. T. Jacques.

British Grey Granite Company, Limited.

Registered March 27th to acquire certain granite quarries and quarrying rights in the county of Carnarvon, and to carry on the business of quarry owners, stone merchants, masons, paviors, contractors, &c. Capital £10,000 in £1 shares. Registered office: Comberton Hill, Kidderminster, Worcestershire.

COMING EVENTS.

Wednesday, April 17.

British Archæological Association.—Mr. C. E Keyser, M.A., F.S.A., on "Sculptured Tympana of English Norman Doorways"; and Mr. T. Cann Hughes, M.A., F.S.A., on "Interments at Bleasdale, North Lancashire," 8 p.m.

Builders' Foremen and Clerks of Works' Institution.—Quarterly meeting, 8 p.m.

Sanitary Institute.—Lectures and Demonstrations for Sanitary Officers, Part II.—Mr. E. Petronell Manby, B.A., M.D., on "The Hygiene of Byres, Lairs, Cow-sheds and Slaughter-houses, and all places where animals destined for the Supply of Food are kept, and the Hygiene of Markets, Dairies, and other places where food is stored, prepared, or exposed for sale, and transported," 7 p.m.

Edinburgh Architectural Association.—Sir John Sibbald on "The Construction of an Asylum for the Insane Poor from the Medical and Administrative Points of View," 8 p.m.

Society of Arts.—Prof. Raphael Meldola, F.R.S., on "The Synthesis of Indigo," 8 p.m.

Building Trades Exhibition opens at the Royal Agricultural Hall, Islington.

Thursday, April 18.

Chemical Society.—Meeting at 8 p.m.

Society of Antiquaries of London.—Meeting at 8.30 p.m.

Institute of Electrical Engineers.—Mr. A. Campbell on "Test Room Methods of Alternate Current Measurements"; and Mr. C. W. S. Crawley on "The Use of the Differential Galvanometer"; announcement of the Council's nominations for the Council 1901-2. 8 p.m.

Sanitary Institute.—Lectures and Demonstrations for Sanitary Officers, Part II.—Mr. James King, M.R.C.V.S., on "Diseased Meat," 7 p.m.

Royal Institution.—Mr. Roger Fry on "Naturalism in Italian Painting"—I., 3 p.m

Friday, April 19.

Architectural Association.—Mr. M. A. Green on "Eighteenth-Century Architecture of Bath," 7.30 p.m.

Institution of Civil Engineers.—Students' Meeting. Mr. E. V. Clark, B.Sc., on "The Theory of Cast-Iron Beams," 8 p.m.

Institute of Builders.—Visit to Building Trades Exhibition, Royal Agricultural Hall, Islington.

Institution of Mechanical Engineers.—Presidential Address by Mr. William H. Maw, 8 p.m.

Royal Institution.—Prof. J. J. Thomson, M.A., F.R.S., on "The Existence of Bodies smaller than Atoms," 9 p.m.

Saturday, April 20.

Sanitary Institute.—Lectures and Demonstrations, for Sanitary Officers, Part II.—Inspection and Demonstration at Knacker Yard at 3 p.m.

Royal Institution.—Mr. John Young Buchanan on "Climate: Its Causes and its Effects"—I., 3 p.m.

Architectural Association.—Visit to Building Trades Exhibition.

Edinburgh Architectural Association—Visit to Duddingston House and Church, and Chapter House at Restalrig.

Monday, April 22.

Royal Institute of British Architects.—Mr. Francis Bond, M.A., on "The Classifications of Romanesque and Gothic Architecture," 8 p.m.

Society of Arts (Cantor Lecture).—Sir William Chandler Roberts-Austen, K.C.B., F.R.S., on "Alloys"—I.

Surveyor's Institution.—Fourth Junior Meeting, at 7 p.m.

Sanitary Institute.—Lectures and Demonstrations for Sanitary Officers, Part II.—Mr. E. Petronell Manby, B A., M.D., D.P.H., on "The Laws, By-laws, and Regulations affecting the inspection and sale of Meat and other articles of Food, including their preparation and adulteration."

Tuesday, April 23.

Society of Antiquaries of London.—Anniversary Meeting at 2 p.m.

Wednesday, April 24.

Geological Society of London.—Meeting at 8 p.m.

Society of Architects.—Annual Dinner at the Prince's Restaurant at 6.30 p.m.

Society of Arts.—Mr. Alexander Siemens on "Patent Law Reform," 8 p.m.

Edinburgh Architectural Society.—Address by Mr. Harold O. Tarbolton, the Hon. President, and Award of Prizes in competitions.

Institute of Sanitary Engineers.—Visit to Building Trades Exhibition.

The Building Trades Exhibition,

ROYAL AGRICULTURAL HALL, N.

Wednesday, April 17th, to Saturday, 27th, inclusive.

GREAT HALL - - - GENERAL EXHIBITS.

MINOR HALL - - - FIRE PREVENTION SPECIAL SECTION

This Hall will be entirely devoted to the Exhibition of Fire Preventio Materials and Appliances under the immediate control of the Fire Preventio Committee.

Chairman of the Executive, EDWIN O. SACHS, Arch., A.M.Inst.M.E.

Chairman of Sub-Committee, F. HAMMOND, F.R.I.B.A.

KING EDWARD'S HALL - COAL SMOKE ABATEMENT SPECIAL SECTION.

Under the Direction of the Coal Smoke Abatement Society.
Chairman, Sir W. B. RICHMOND, R.A.

Open from 10 a.m. to 10 p.m.

BUILDING TRADES' EXHIBITION, 1901.

THE Building Trades' Exhibition now open at the Royal Agricultural Hall, Islington, N., is certainly the best, as it is the largest, of its kind ever held in this country. The stands have been carefully decorated and arranged, and the exhibits are thoroughly comprehensive of all that is new in the building and allied trades; so that the Exhibition demands a visit from all architects, builders, engineers, decorators, and others similarly engaged. Though more extensive than any of its predecessors, it preserves much of their character, and many familiar features meet the eye of the visitor.

As our issue is published on the same day as the Exhibition opens, it is of course impossible for us to give a full account of all the exhibits, but by making forward arrangements we have been enabled to compile a goodly number of notices, which we now publish in the form of a Supplement. The remaining notices will be incorporated with those now given, and all will be published in our next issue as a Special Exhibition Supplement.

THE BUILDERS' JOURNAL.

As usual, the BUILDERS' JOURNAL AND ARCHITECTURAL RECORD occupies a stand at this Exhibition (No. 81, Row C, close to the band stand). Here are displayed copies of our own periodical, and also of that finely-illustrated magazine "The Architectural Review," which is also published at these offices. "Specification," which is so highly esteemed by all architects, builders and engineers, is also exhibited. Our representatives will be happy to supply advertisers and readers with all information in any way affecting the publications referred to.

JULIUS HÜLSEN & CO.

Messrs. Julius Hülsen & Co., of Newcastle-on-Tyne, in their exhibit, demonstrate the efficiency of their precipitated carbonate of barytes as a preventative against scum and discolouration in facing bricks, terra-cotta, ridges, quarries, &c. Specimens are shown from the same seam of clay, partly with and partly without an admixture of the carbonate of barytes. Those made without the barytes are scummed, whilst those with which the barytes has been mixed are quite clean and of a good colour. "Linkum" Patent Belting is also exhibited at this stall. This is a belting made up of links punched from manufactured sheets of specially-prepared and highly-compressed fibre. Being made in this way, every link is as strong as its fellow; and as it is claimed that a "Linkum" link is of considerably greater tensile strength than the best leather link of the same section, the belt is very serviceable.

STANLEY BROTHERS, LIMITED.

Messrs. Stanley Brothers, Limited, of Nuneaton, have the following exhibits on their stand:—White and coloured enamelled bricks; improved salt and grey granite bricks, for Board schools, hospitals and public buildings; red and buff chimney pots; brown and glazed cane sinks; ornamental red and buff terra-cotta; glazed socket pipes and connections; semi-encaustic paving tiles; blue pressed bricks, garden tiles, &c.; red ridge tiles, finials, ventilating bricks, &c.; red and buff terra-cotta and glazed vases; roofing tiles, malt kiln tiles; Staffordshire quarries, ridges, &c. This firm has branch works at Burslem and Willenhall, near Coventry, and collieries at Nuneaton and Bedworth.

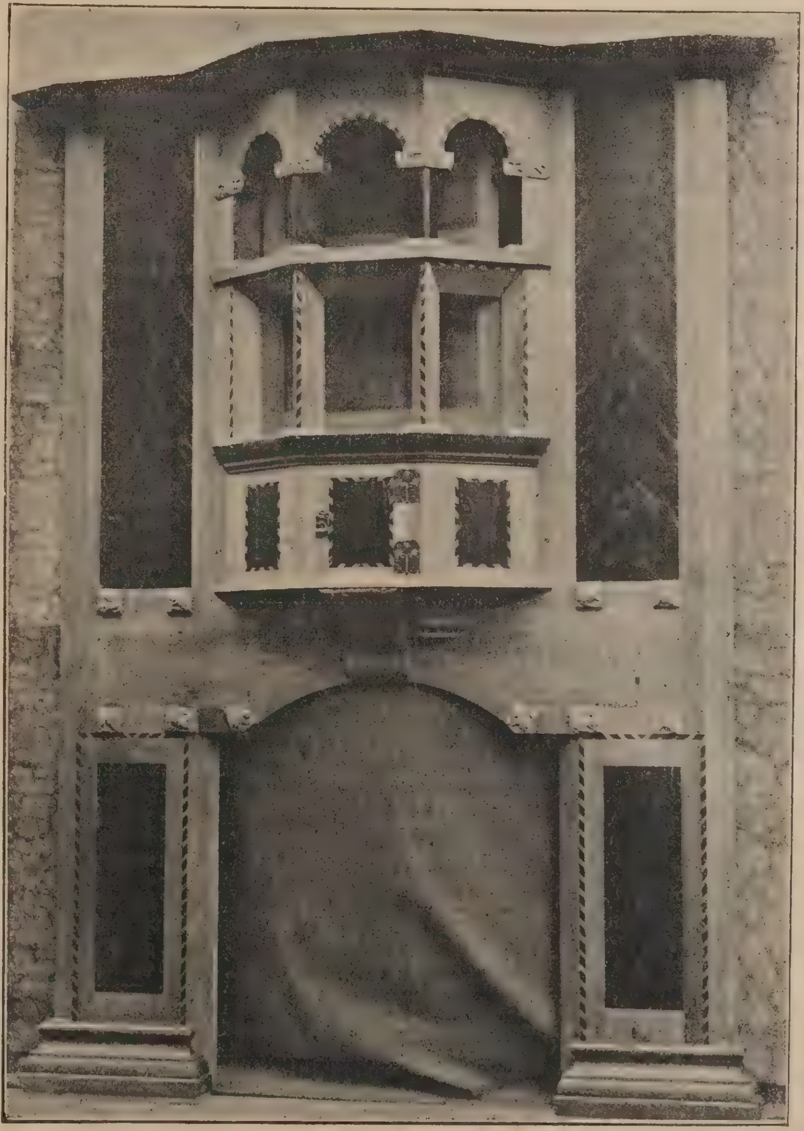
JOHN P. WHITE.

As a maker of beautiful mantelpieces and garden furniture Mr. John P. White, of the Phyghtle Works, Bedford, occupies a prominent place in this country. The exhibits at his stand (No. 68, Row C) are fine specimens of design and workmanship. It is sufficient to mention that he has work from the hands of such men as Mr. H. Wilson, Mr. C. H. Quinnell, Mr. G. M. Elwood, to draw attention to his exhibit. We illustrate a mantel by Mr. Wilson to be seen at this stand. It is in oak with coromandel inlay. Mr. White's garden seats and gates have none of that foolish gewgaw which passes under the name of "ornament," but show a quiet restraint in design which is most desirable for all articles associated with a garden. The "Phyghtle" garden seat (by Mr. Quinnell) is particularly happy in treatment. In his new catalogue of garden furniture, Mr. White says: "The good results produced by my garden seat and gate catalogues, and the recent development in the craft of gardening, have suggested to me that there must be many gentlemen—members of the architectural profession and others—who are anxious to obtain some modern representations of the various quaint conceits and devices which contribute so much to the charm of the Old English Garden." And in this, with the assistance of Messrs. Forsyth & Maule, Mr. Quinnell, and Mr. James S. Cooper, architects, Mr. White has certainly succeeded. We would call special attention to the manner in which these catalogues are produced; they are well printed on good paper, and are illustrated by line drawings of very considerable merit. Roberts' drawing-board rest, fixed by four screws, is also to be seen at this stand.

C. D. MONNINGER.

Saw-sharpening machinery is the special feature of the exhibit of Mr. C. D. Monninger, St. Anna Saw and File Works, 124 and 126, Clerkenwell Road, London, E.C. The improved latest pattern "Climax" band-saw sharpening and setting machine is to be seen at work. This machine will sharpen band-saws of any length up to $2\frac{1}{2}$-in. wide, provided the teeth are not more than $\frac{5}{8}$in. space, and the sharpening is done quite automatically, so that there is a great saving over hand work, to say nothing of accuracy.

The improved saw-sharpening machine for circular saws and mill webs is also to be seen at work. Much prominence is given to guards for dangerous machinery, the Couzens' patent automatic saw guard being shown fitted to Monninger's improved rising and falling top saw-bench. Another exhibit at this stall is the patent "Practical" moulding machine guard fitted on a latest pattern vertical-spindle moulding machine. This is made specially for the use of builders; and as the workmanship and material are of the best, and it is constructed most solidly, it can be employed for the heaviest work with the greatest ease; it can be run at 6,000 revolutions



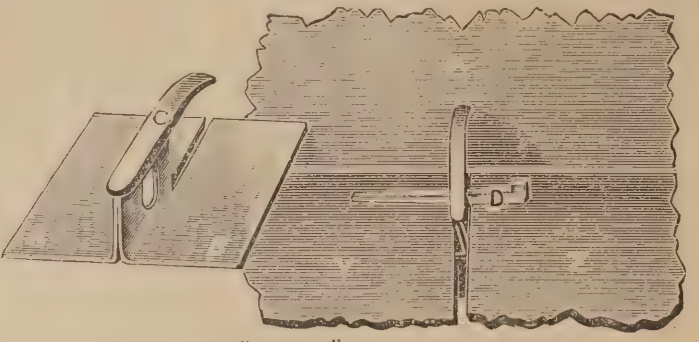
MANTEL DESIGNED BY H. WILSON FOR JOHN P. WHITE.

per minute without vibrating in the least. Monninger's patent hand-feed planing machine guard has recently been still further improved, and is shown fitted to a "Victory" hand-feed planing machine.

Among the numerous other exhibits are improved joiner's and sash cramps, and safety glue-heaters, which meet with the approval of H.M. Inspectors. With regard to these latter, it is impossible for a fire to occur through their use, as the flame does not come in direct contact with the glue pots.

PRYKE & PALMER.

Messrs. Pryke & Palmer, whose offices are at 47 and 48, Upper Thames Street, E.C., have their stand in Row F, No. 123; and among a number of interesting exhibits shown, there is the patent "Perfik" roof-slate fastener, illustrated on this page. For repairs to slate roofs, this is intended to supersede the old-fashioned lead or zinc strips. Its particular advantages are that one fastener binds three slates, that it will not shift by wind or sliding snow, holds the bottom edge of slate down, is scarcely perceptible on a roof, and will not catch or tear workmen's clothes. In fixing the fastener, the damaged slate is first removed, and replaced with a new one, as at X in illustration. The flanges A B of strap are shipped under the old slates Y Z, the part C standing up between. The strap is then pushed upwards until the notch in part C retains the bottom edge of the new slate X. The wedge D is inserted into the hole in fastener, and driven until sufficiently wedged to secure the slate from slipping.



THE PATENT "PERFIK" ROOF-SLATE FASTENER.

Another novelty shown is Fullerton's patent metallic connections for w.c. pans, in lead or brass, with short or long arm connectors.

FLEMING, BIRKBY & GOODALL, LIMITED.

The "Teon" belting made by Messrs. Fleming, Birkby & Goodall, Limited, of Halifax, may be examined at their stand. This belting has been put to several tests, and has proved itself a good article. It is a most suitable belt for trying positions, or in countries where adverse and extreme climatic influences prevail, "Teon" being absolutely unaffected by the rays of the hottest sun, the most humid or steamy atmosphere, or the keenest frost, no matter how constant or interchangeable any of these conditions may be. Tests prove the ability of the belt to resist the action of dry heat up to 230 degs. Fahr., steam up to 200 degs. Fahr., damp, water and open air exposure; also oil, grease, alkalies and acids (with the exception in the last-named of bi-sulphide of carbon and chloride of sulphur). The basis of "Teon" is a specially-woven fabric, made up without joint or seam, thus securing perfect uniformity and evenness of driving. This cloth is built up in piles, then cemented together under enormous pressure. The cement is a secret preparation, and is the prime factor in enabling the belt to resist influences potentially deleterious in their nature. No ingredient used in this cement is influenced by any heat under 230 degs. Fahr.; and even at a higher temperature the cement is equally efficacious in its adhering power, and the "life" of the belt is in no way impaired. Every belt is moreover passed through a specially-devised stretching apparatus, so that practically all "stretch" is taken out, and the total result is a sound, reliable, and high-grade belt.

THE STONEHOUSE WORKS COMPANY.

The Stonehouse Works Company is the engineering business of Mr. Edward Tailby, timber merchant and general woodware manufacturer, of 76, Summer Row, Birmingham. Several saw benches are to be seen at this stall. The improved patent high-speed saw bench exhibited is arranged for cutting and ripping deals and battens at a very high rate of speed, dealing equally well with round timber that has once been broken down. The bench is all in one heavy massive casting, and is fitted with a steel spindle, with extra large pulleys, running in three long gun-metal bearings, the outer bearing being self-contained with the bench, and thus preventing any vibration of the saw or spindle, or heating of the bearings through tightness of the belt. The patent radial arm (which can be fitted to any existing make of saw bench) enables work to be executed with very great rapidity. The machine is also provided with a patent pressure attachment and saw guard.

In the patent self-acting cross-cut saw bench the wood is placed on the table against the fence, and the stop set at the length required, and by the simple movement of the lever the saw travels, cross-cuts, and returns to its position in four seconds, thus enabling a deal about 14ft. long to be cross-cut into six pieces in less than half a minute. Fifteen gross of boards, 36in. long, were cross-cut in one hour; and it is here opportune to mention that these statements are absolute facts, and not misrepresentations. The fence is arranged to turn right over, leaving the top quite clear for ripping.

Tailby's patent planing machine has a patent feed which is instantly turned over for rapid planing, moulding, rebating, &c.; this can be varied by means of change wheels, up to 3,000ft. run per hour, and entirely does away with the great danger of the operator getting his hands in the cutters. The feed can be fitted to any existing hand-planing machine.

The patent hand and steam power central rack rising top saw bench is a handy tool. It will take a 15in. circular saw, and will cut 5in. deep. The fence is adjustable every way, and swings clear over for cross-cutting. Other saw guards and machines are also to be seen at this stand.

FIREPROOF PARTITION SYNDICATE, LTD.

The Fireproof Partition Syndicate, Limited, of 10, York Buildings, Adelphi, W.C., exhibit at Row B, Stand 48, a two-roomed "week-end" bungalow composed of their patent dovetail corrugated metal-sheeting, while a gate-keeper's office is exhibited in the fire-proofing section. The sheets are formed by patent machinery into dovetail grooves, which form an excellent double key for any kind of plastic material, thus rendering them solid, fire-, sound-, damp-, and vermin-proof walls only 2in. thick. The sheet being without perforations, there is no waste of plaster, or any fear in case of fire of flames passing through after the plaster has fallen away from intense heat. The roofs of the buildings shown are also made with the patent sheeting, plastered, with tiles embedded. The saving in space in a building where these partitions are used means a nett gain of 4in. on each partition. One partition saves 4in.; two, 8in.; three, 12in.: thus, with three partitions, saving 1 cubic foot through the entire building, as the 2in. partitions are equal in strength to a studding partition 6in. thick. The firm also show samples of paten fireproof floors, constructed on a similar principle. They can be both cheaply and speedily erected, and can be plastered immediately if required, while it is claimed that the weight per foot super. is considerably less than that of any other fireproof floor on the market to-day.

GEORGE PRICE, LIMITED.

All those in need of a good safe should inspect the "Twentieth Century" bent steel side-locking safe to be seen at the stand (in the Fire Prevention Section) of Messrs. George Price, Limited, of Wolverhampton. The outer shell is bent cold by powerful hydraulic machinery out of a single steel plate, from ¼in. to ½in. thick, so that the corners are solid and jointless. Back plates, of ¼in. to ½in. steel, are put in from the front and firmly secured to steel flanges overlapping the backs. The door frames are of special section T-steel, absolutely wedge-proof. Doors are of ⅝in. to 1in. solid steel. The safe is lined throughout with 3¼in. chambers, tightly filled with improved steam-generating composition. Chambers on doors, 4in. to 5½in. thick, are filled entirely with fire-proof composition. The doors are secured at the back by a continuous bar, which, when the door is closed, passes behind the solid web of the T-section door frame. The fronts of the doors are fitted with wedge-shaped dowels slotted out at their front edges, which pass through corresponding openings in the door frames. The safe is locked automatically without applying the key to the lock. The act of pulling the handle to the right causes the locking bar to slide up the slots in the dowels, and the safe is made secure. The T-steel frames of the safes in which the lock and locking mechanism are fixed are "case hardened," and protect the locks from drilling at all points. In the better qualities the doors are "case hardened," and are drill and sledge-hammer proof; they are also banded back and front with endless wedge-proof bands shrunk on hot like the tyre of a wheel, and securely covering up the rivets and screws. The "Twentieth Century" strong-room door can also be inspected at this stand. This also locks on the side, has a 5½in. fireproof chamber on the door filled with fireproof composition, and is constructed in a similar manner to the safe above described. The firm has been established for more than fifty years, and has supplied safes to H.M. Board of Works, War Office, Admiralty, Bank of England, foreign Governments, and numerous large companies.

STANDARD SANITARY MANUFACTURING CO.

The Standard Sanitary Manufacturing Co., who exhibit at Stand No. 82, Row C, have opened London showrooms at 22, Holborn Viaduct. The head office of the firm is at Pittsburg, U.S.A., but they have established branch offices and agencies in all the principal cities of the world, and are now placing on the market high-class porcelain enamelled baths, lavatories, and similar goods. The "Standard" baths were awarded the only Grand Prix at the Paris Exhibition of 1900, and also the gold medal of the Department of Hygiene and Social Economy. The firm control practically every cast-iron enamel bath made in the United States, but none of the plants so controlled produce the bath styled "Standard," which is made only at the works in Allegheny, and under a secret process not granted to the other plants. The following is a specification of an "Elysian" bath: White enamelled bath tub, with 3in. enamelled roll rim; brass common overflow connected with nickel-plated overflow; waste plug with rubber stopper; width, 23½in.; depth, 18½in.; height from floor, 24in.; length over rim, 4ft. 5in.; length inside, 4ft.; price, £7 5s.

Mr. Leon N. Loeb is the general manager for the United Kingdom.

MOORE'S PATENTS COMPANY, LIMITED.

The exhibit of Moore's Patents Company, Limited, Nightingale Hall, Lower Edmonton, N., is to be seen at Row C, Stand No. 65. When the sashes of Moore's patent vertical sliding sash windows are at the bottom they are always hinged, and then a person standing inside on the floor can, by moving a handle, turn them inside and paint, repair, or clean the outside, and replace them, as easily as an ordinary door is opened and closed, without steps, poles, risk of accident or detachment. These sashes cannot be opened inwards until they are down and hinged, and when turned inwards for cleaning or full, ventilation, they cannot become unhinged, or get wrong when being replaced. When specified of similar material and shape they cost no more to make than ordinary windows.

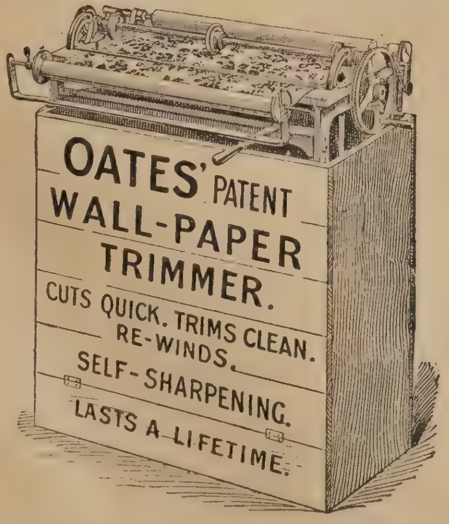
Both frames in Moore's patent casement windows are exactly the same as in ordinary casements, opening outwards, with solid or nailed-down beadings. By moving a catch on the inside with the finger when the sash is open, the outside will turn inside for cleaning; the sash can be replaced, and the catch pushed back, with great ease and rapidity. When fitted with a non-rattling stay and catch they cost only a trifle more than the ordinary casement. Other exhibits at this stand are: Patent fanlight or skylight openers, two-way door springs and hinges, and one-way door springs. The two-way door springs are screwed on the floor (without cutting a hole for them) and on the bottom of the door, and are almost invisible. They have a screw adjustment to suit them to heavy or light doors, and the wearing part runs in oil.

T. FEWSTER WILKINSON.

Mr. T. Fewster Wilkinson feels that as the present form of stairs has been in universal use since very ancient times (possibly since the Pyramids of Egypt were built) there will be a good deal of inherited prejudice to overcome in the adoption of his own patent stairs. These are designed to combine easier risers with wider treads than can be arranged on the ordinary system, and instead of being level across the whole width of the stairs the treads alternate to the right and left. Handrails at each side guide the person in the centre of the staircase, and he places his left foot on the left-hand steps and his right foot on the right-hand steps. There is one more riser on the left-hand side (looking upwards) than on the right-hand side, so that both the ascent and the descent begin with the left foot, as a soldier does in marching. At an angle of 45 deg., the risers and treads can be in the following proportions: 5½in. by 11in., or 6in. by 12in., or 7in. by 14in.; instead of equal risers and treads, as in the ordinary system. At lesser angles easier risers and wider treads can be provided. The stair exhibited is at an angle of 50 deg.; there are eleven risers for a height of 5ft. 0½in., each riser being only 5½in. high; the treads are 9¼in. wide; the "going" is only 4ft. 2⅞in. The stair exhibited has been made with unusually easy risers for the purpose of showing the vast difference between the new system and the ordinary stair delineated on the outer side of the string-board, having seven risers, each 8⅝in. high, and treads only 7¼in. wide. Mr. Wilkinson's address is Bartle Garth, Reepham-by-Lincoln.

J. OATES.

The exhibit at Stand 31, Row A, consists of a number of "Empire" patent wallpaper trimming machines made by Mr. J. Oates, of 24 George Street, Huddersfield. These are shown in operation, edging all kinds of wallpapers, from common pulps, grounds, and sanitaries, &c., up to Anaglypta; and that so expeditiously and at the same time so accurately, that visitors cannot help being struck with the great difference between the results obtained by the use of this neat little labour-saving machine and the old-fashioned, slow, and tedious method of work with hand scissors; indeed, the latter method must finally become a thing of the past, as an ever-increasing number of these wallpaper trimmers are being used throughout the Kingdom and abroad. The 1901 model shown at this stand embodies the very latest improvements in trimming machines.



OATES' PATENT
WALL-PAPER
TRIMMER.
CUTS QUICK. TRIMS CLEAN.
RE-WINDS.
SELF-SHARPENING.
LASTS A LIFETIME.

A. T. COOPER.

Mr. A. T. Cooper, of 92, Moray Road, Finsbury Park, London, N.W., is the inventor and patentee of a patent suction and vacuum pump which has been submitted to many severe tests by competent authorities, and has given satisfaction. On December 16th, 1893, a War Office test was made at Wellington Barracks. A tier of latrines was choked. The pump was set to work and withdrew a full-size lemonade bottle in one minute. A manhole was also cleaned in the same time. On another occasion a test was made with a large gulley outside the married quarters at Lincoln Barracks. From a 4in. outlet the pump withdrew a child's wooden sand spade 15in. long, and on the same day also cleared a very obstinate obstruction in the laundry drain. In the course of a test with a set of three closets at Netley Hospital, the pump withdrew the third of a dinner plate in five minutes. The pump is therefore of ample strength. The London School Board have 100 of these drain clearers in use, while the Commissioners of H.M. Prisons have provided the whole of their prisons, 60 in number, with Cooper's Patent Drain Clearers. H.M. Office of Works is also supplied throughout with them. The exhibit at this stand also includes Cooper & Bryant's patent "Clincher Lock of the Future." The bolt has an opening at the end which slides over and clinches the catch firmly, fastening the door so that it cannot be prized open from the outside. A locked shutter is also provided to protect the keyhole.

WATERPROOF CEMENT COMPANY.

Waterproof cement is a material as yet imperfectly known on the English market, but it is one deserving the earnest consideration of architects and contractors. It is exhibited at the stand (No. 137, Row F) of the Waterproof Cement Company, who have works at Brentford and offices at 6, Millbank Street, Westminster, S.W. Portland cement mixed with this composition becomes impermeable to water. The material is used under ordinary conditions, no heat being required for mixing. Frost will not affect it when properly mixed and set, and it is so compact as to be practically imperishable. It is specially applicable to reservoirs, cellars, barracks, ammunition magazines, fine-art galleries, libraries, damp-proof courses, plastering, pointing, and positions where exposure to damp renders ordinary cements unreliable. The longer it is set the harder it becomes, and the colour may be varied so as to harmonise with existing fabrics. This waterproof cement takes paint readily, and can, if desired, be faced with ordinary Portland cement. Samples will be forwarded on application, and the company will be pleased if these be submitted to any practical tests that may suggest themselves. The amount used in combination with Portland cement and sand forms about 10 per cent. of the bulk, and the cost is about 10 per cent. more. The cost, £12 10s. per ton, free on rail, in lesser quantities 14s. per cwt., is thus very nominal in view of its waterproof and lasting quality. Packages are charged at cost, credit being given on return in good condition within two months, carriage paid.

Samples are also exhibited on this stand of the "Standard" damp-proof composition. With a lining of this material properly applied, a guarantee is given that no house or place will show evidence of damp. It is applied in a molten state, and sets quickly. The result is a rock-like mass, without fissure, absolutely impermeable to water. It is a non-conductor of heat and sound, does not harbour disease germs, and is positively vermin-proof. The "Standard" composition is sent out in blocks or in bags. Its price is £5 5s. per ton, free on rail, lesser quantities at 6s. 6d. per cwt.

MELDRUM BROS., LIMITED.

The exhibits of Messrs. Meldrum Brothers, Limited, of Atlantic Works, City Road, Manchester, will be found at Stand No. 109, Row E. The specialities exhibited are the "Meldrum" forced draught furnace, the "Koker" stoker combined with forced draught, and refuse destructor.

The "Meldrum" forced draught furnace is suitable for all types of steam boilers, and is very largely used at brick and tile works, as well as at every other description of works where steam power is employed. The chief advantages of these furnaces are: (1) For greatly increasing the steam power of the boiler beyond what natural draught will give; (2) for effecting economy by the use of cheap fuel; (3) for overcoming defective chimney draught; (4) for minimising the emission of smoke; and (5) the cost of upkeep is exceedingly small, even the bars lasting for years.

The "Koker" stoker combined with forced draught is adapted for mechanical feeding on the coking principle, and the combination gives results claimed to be in advance of any other mechanical stoker, especially as regards high boiler duty, fuel efficiency, and smokelessness. Stokers have been fitted for a number of the largest steam users in the country, and Messrs. Meldrum Brothers have a large number of them in hand, including twenty-two boilers for one large firm, eighteen boilers for another, and many other important orders.

Refuse destructors are now being erected by this firm for numerous cities and towns in England and Scotland, besides which there are a good number already at work. The main advantages of the Meldrum system are that it destroys the refuse entirely without any objectionable fumes or nuisance of any kind, and at the same time produces the highest possible steaming power from the refuse, this steam being used for electric lighting, sewage pumping, or other useful municipal purpose. The high temperatures maintained in the destructors ensure the thorough cremation of the fumes &c.

H. J. & C. MAJOR, LIMITED.

Majors' patent waterproof roofing tiles are the leading feature of the exhibit of H. J. & C. Major, Limited, of the Patent Tile Works, Bridgwater, at Stand No. 106, Row E. The various patterns of these tiles are well known for their general utility and efficiency, combined with economy. Their adaptability for buildings of every description has been shown by the adoption of them by leading architects, and by the demand for them by landowners, contractors and builders for all kinds of roofing purposes in the United Kingdom, the British Colonies, and foreign countries. The general assortment of ridge tiles, paving bricks, oven bricks, ornamental, and other building bricks deserves special attention, as well as the roofing tiles above referred to. Messrs. H. J. & C. Major, Limited, have been awarded the highest and only award for roofing tiles in every competition in Great Britain and Ireland since 1884, and also the highest and only award for roofing tiles at the Paris Exhibition, 1900.

CROSSLEY BROTHERS, LIMITED.

The exhibit of Messrs. Crossley Bros., Limited, of 10, St. Bride Street, E.C., in Wall Space No. 124, consists of the following engines: One type "U" gas engine of the latest pattern, capable of developing 33 effective h.p. as a constant working load. One type "OE" high-speed electric lighting gas engine fitted with one specially heavy fly-wheel, supported by outside bearing. This engine is capable of developing 12½ brake h.p. as a constant working load, and is used for driving a dynamo for lighting this stand. A perfectly steady light can be obtained with this type of engine, without accumulators. One type "JJ" oil engine, capable of developing 1½ brake h.p. as a constant working load. The "U" type above referred to drive the brick-making machinery on the adjacent stand of Messrs. Thomas C. Fawcett, Limited, engineers, of Hunslet Road, Leeds. Also, in addition to the above, there is one of the "M" type gas engines, capable of developing 7 brake h.p. as a constant working load, on Messrs. Pullman and Mann's Stand, Leeds; and an "S" type engine, giving 20 brake h.p., on the stand of Messrs. Bradley & Craven, of Wakefield.

SHEPWOOD & COMPANY.

The "Shepwood" patent partition brick, made by Messrs. Shepwood & Company, of Lindisfarne, Walton-on-Thames, can be inspected in the Fire Prevention Section of the Exhibition. It has hollow spaces passing vertically through it, so arranged that when the bricks are placed over one another with bonded joints the spaces are continuous. It is claimed that a partition constructed with these bricks, finishing 2½in. thick, is as rigid as an ordinary 4½in. wall; it will support itself across a wide span, and may be used in place of fire-spreading lath-and-plaster partitions, and for closet and lavatory divisions, articles and dormitory partitions, where space is valuable. The size of the bricks is 13½in. by 6in. by 1⅞in. thick. No ironwork is used in construction. These bricks have been used in numerous important buildings, such as the North-Eastern, St. George's, and St. Thomas's Hospitals; the Stock Exchange; Bank of Scotland, Bishopsgate Street; Victoria Theatre, Manchester; and Pitman Schools, Southampton Row.

S. T. CLOTHIER.

Mr. S. T. Clothier, quarry owner and stone merchant, of Street, Somerset, exhibits at Stand No. 34, Row A, flags, steps, and kerbs of Keinton stone, a very fine-grained blue-greystone. Flags and kerbs of this stone are very suitable for public footpaths, and are in use throughout the Midlands and South of England for this purpose. The rubbed flags for paving public buildings of all kinds have been used in the Royal Courts of Justice, Strand; and for tennis and racquet courts at Princes' Club, Knightsbridge, the University Club, Cambridge, Sir A. Noble's, &c. Their price is 1s. per ft. cube at the quarries, which are at Keinton, Somerton, and Street, in Somersetshire.

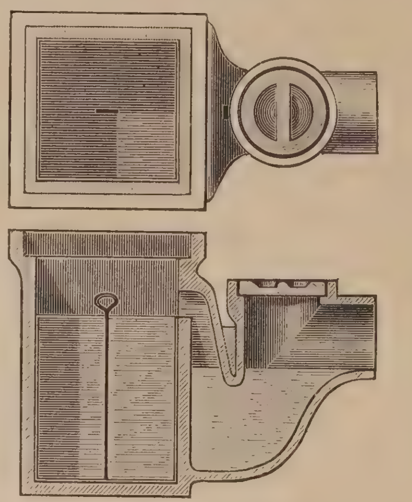
Blue and grey blocks are also shown of forest stone, a fine grained blue and grey sandstone, suitable for steps, landings, monumental and general architectural purposes, in general use throughout the Midlands and South of England. The price of this stone is 2s. per ft. cube at the quarries, which are at Knockley, Darkhill and Gosty Knoll, Forest of Dean, Gloucestershire.

HOULDSWORTH'S PATENT BARROW COMPANY.

The exhibits of Messrs. Houldsworth's Patent Barrow Company, of Park Lane, Keighley, at their stand in a Gallery bay, consist of barrows and barrow fittings. One of the great faults in ordinary barrow wheels is the constant repair necessitated by the failure of the axles. In Houldsworth's patent wheel it is claimed that this is entirely obviated by making the axle of the wheel really of two-flanged axles of steel bolted through the stays, which are of wood, and form a cushion to the axle. As the axles work in patent Bush bearings, the liability to get out of order is reduced to a minimum. The wheel is stated to always run true and to outlast several of the usual make. The Bush bearings referred to are driven in with a hammer into the usual hole bored in the axle block. Barrows can be fitted with patent adjustable bearings if required.

JOSEPH PLACE & SONS, LIMITED.

The chief exhibits of Messrs. Joseph Place & Sons, Ltd., of Darwen, Lancs. (who occupy Stand No. 135, Row F), are the "Adi" and "Zaza" chimney pots, the patent kiln bottoms, and Place's patent street gulley. The "Adi" and "Zaza" chimney pots are designed to prevent smoky chimneys, by means of having double-arms and louvres, the former with the louvres below the arms and the latter with them above. In the "Adi," when there is a direct down-draught, the wind rushes in at the top and out at the side arms, thus creating a vacuum in the flue. The smoke ascends the flue to fill this vacuum, and is driven out at the side arms. The stronger the wind that falls on the top of the chimney, the better the chimney pot answers. The "Zaza" chimney pot should be used where the wind re-bounds from a high building; as the "Adi" will not in all cases answer under these conditions. The "Zaza" increases the up-draught and prevents a down-draught. The patent chequer bricks for kiln bottoms give increased strength and decreased solid on floor level; rubbish cannot lodge on the supporting walls, nor between the chequers, the supporting walls are tied together and lateral movements are prevented, and a 4-in. pipe can stand anywhere and still have free draught. These kiln bottoms should be seen to be appreciated. The special advantage of the patent street gulley, which is illustrated on this page, is that by the arrangement of the outlet the whole depth of the gulley is utilised for sediment, and still the outlet and gulley are accessible in every part. This distinctly advantageous arrangement is stated to be quite as cheap as the ordinary gulley. Samples of white enamelled and special salt glazed bricks are also shown; these are made from the firm's "diamond" stoneware clay, which enables a brick to be made perfectly true on the bed and still get the same high glaze as other makers.



PLACE'S PATENT STREET GULLEY, NO. 249.

MOFFATT & EASTMEAD, LIMITED.

Moffatt & Eastmead, Limited, lift manufacturers, of 39, Victoria Street, S.W., occupy Bay No. 5. Here may be seen an electrically driven warehouse lift, the hoisting machine being fitted with a self-sustaining shaft in place of worm gear, and having an automatic mechanical stop action provided to prevent overwinding. A patent self-sustaining hand-power goods lift which requires neither brake nor brake rope (as soon as the operator releases the hand-rope, or should the latter come off the wheel, or break, the cage remains stationary and will not run away even when fully loaded). A patent self-sustaining hand-power dinner lift for flats and private houses. Improved patent automatic safety gates for protecting the entrance to lifts. A belt driven dispatch sack hoist for granaries, breweries, stores, barrow hoisting, &c. A self-sustaining hoisting crab which dispenses with both brake and ratchet, and will not allow the handle to fly back. The warehouse lift and sack hoist are shown working, and are driven by a 3-h.p. electric motor supplied by the General Electric Company, Limited. Another exhibit is one of Moffatt's improved 1900 patent feed-water heaters and fuel economisers for steam boilers. This heater, by which dirt, lime, salts and other impurities are prevented from entering the boiler, is very compact. Each of the internal tubes is fitted with an independent expansion joint, and when utilising the exhaust steam from a steam engine it will deliver water into a boiler at from 206 degs. to 208 degs. Fahr., the water being purified and softened in its passage through the heater. A large number of these heaters are in use in breweries, factories, laundries, &c.

In designing their hydraulic lift Messrs. Moffatt & Eastmead's main object has been to secure safety and economy. The former has been attained from results gained in actual practice, and the latter by reducing the number of parts to a minimum, rctaining only those necessary to efficient working.

L. LEWIS & Co.

Messrs. L. Lewis & Co., of 51, Shirland Road, Paddington, W., are the manufacturers of the flexible damp-course, patent mastic roofing felt and slaters' felt to be seen at Stall No. 17, Row A.

The damp-course is manufactured by a chemical process, and is not liable to crack or ooze out under pressure. It is manufactured in lengths of 33ft. (widths to order), thus having an advantage over 32in. slabs and saving from 25 to 30 per cent. in material and labour. It can be rolled along the wall and kept down to the mortar, avoiding frequent overlapping, in which case it would not be a true damp-course, whereas if cut in slabs it would take 12 overlaps of 3in. each, or 36in. in all.

The flexible mastic roofing felt is manufactured on the same principle as the damp-course. Messrs. Lewis claim that this felt is much superior to the ordinary straw or fibrous felt, both in strength and durability. Their felt is largely used for roof covering (under slabs or tiles), and being of close texture insects cannot penetrate it. Sparks or lighted matches falling on it will not affect it. By reason of its cheapness and portability it is particularly adapted for shipment to the Colonies, while its non-conducting quality renders it effectual in resisting the sun, the cold winds and the winter frosts. The mastic slaters' felt is manufactured on the same principle as the roofing felt, but is thinner in substance.

The price of the mastic damp-course, extra quality, 9in. wide, is 4d. per lineal yd. in rolls of 11yds. The roofing felt costs 5s. 6d. per roll of 11yds. by 39½in. wide (contents about 108ft. super.). The slaters' felt, 11 or 22yds. long, 39½in. wide, costs 3s. and 6s. respectively (contents of rolls about 108 and 216 super. ft.).

These goods have been supplied to the War Office, Admiralty, General Post Office and other Government offices.

H. C. SLINGSBY.

The patent trucks made by H. C. Slingsby, of 142, 144, 146, Old Street, E.C., where there are 20,000 sq. ft. of show-rooms, are too well known to need much description. They are obtainable in various sizes for all trades, run both ways, spin like a top, and have a sliding wheel at each end. A number of these trucks are shown—being a selection from 400 styles and sizes listed, and 1,000 styles and sizes to be seen—at 142, 144, 146, Old Street, E.C., which is the new address of the firm. The offices were formerly at 30, Gray's Inn Road, E.C. Mr. Slingsby's exhibit occupies Wall Space 157.

Visits and Meetings during the Exhibition.

The following is a list of the visits and meetings that will take place during the time the exhibition remains open, from April 17th to the 27th:—

Friday, 19th.—Visit of Institute of Builders.
Saturday, 20th.—Visit of Architectural Association.
Wednesday, 24th.—Visit of Institute of Sanitary Engineers.
Thursday, 25th.—Visit of Society of Architects. Annual meeting and dinner of Institute of Clayworkers.
Friday, 26th.—Conference on standardising of bricks, at 4 o'clock.

In respect to the standardising of bricks, this Conference has been arranged jointly by the Royal Institute of British Architects, the Institution of Civil Engineers, and the Institute of Clayworkers. The chair will be taken by Mr. Thomas Blashill, F.R.I.B.A. Anyone desirous of attending this meeting may obtain admission to the Hall upon application to 43, Essex Street, W.C.

A party of fifty Germans engaged in the building industries will pay a ten days' visit to England for the purpose of seeing the exhibition. They will be entertained at a banquet at the Hall by the Institute of Clayworkers on the Thursday evening, April 25th.

An Architectural Causerie.

Scenic Art. THE past week has been remarkable for two utterances on the interesting topic of scenic art. The revival of "Coriolanus" by Sir Henry Irving at the Lyceum Theatre has, naturally, excited the attention of stage enthusiasts, and the production gains an enhanced interest from the fact that Sir Laurence Alma-Tadema, the artistic authority on Rome and Romans, is responsible for the scenes and dresses. In a chat with a "Daily News" interviewer Sir Laurence showed very clearly that in his opinion dramatic action gains from suitable surroundings, an opinion with which the majority of playgoers will be prepared to agree. It is interesting to note that the designs for "Coriolanus" were prepared about twelve years or so ago, and the scenes as now presented at the Lyceum are, with slight exceptions, identical. Sir Laurence pays a tribute to Shakespeare's genius in entering into the spirit of the times he depicted, and states that many things which the poet conjectured have been established by subsequent researches. Mr. Percy Fitzgerald's paper upon the true principles of stage scenery, read before the Society of Arts, takes an entirely opposite view, and is not by any means so conclusive. Mr. Fitzgerald ridicules many of the devices used to produce illusion in theatres; but the theatres from which he has collected impressions would appear to be third-rate provincial houses in which the scenic accessories of travelled-stained "fit-up" companies usually find a home. To attribute such a standard to the productions of Her Majesty's and the Lyceum theatres is simply a travesty of reasoning. No one, we presume, would argue that scenic art has yet attained perfection; but the efforts of our leading managers to produce illusion in this direction have naturally fostered inventive talent, and led to the appearance of new methods and new material. There are yet difficulties in the way of "sky-borders" and other unruly details which require improvement; but we have little doubt that these difficulties will ultimately be surmounted. Mr. Fitzgerald cannot find any virtue in built-up scenery. "No dramatic advantage was secured by making people ascend or descend flights of steps, or cross bridges, or enter the porch of a church, as all those operations could be described or suggested." Mr. Fitzgerald does not show how these operations could be described or suggested; and we cannot imagine any attempt to do so that would not excite the ridicule of the audience.

But on the general statement we join issue. The "processional" part of a play has a distinct dramatic advantage in creating an "atmosphere." To prove it we can take one or two examples. In Mr. Tree's production of "King John" the curtain rose on an empty stage, save for one attendant standing at the head of the staircase in full view of the auditorium. The pealing of the organ, the entry of the chanting monks, the acolytes with swinging censers, the procession of the Court down the steps, all contributed to dramatic action in carrying the minds of the audience away from the small-talk of the nineteenth century to the spirit of a time centuries back, when religion, more feared than believed in, dominated the lives of the people.

Similarly, the spectacle of the mad king Herod, clothed in rags amid the splendour of his court, stricken with catalepsy by his wife's bier, with the Roman envoy offering him kingdom, titles and sceptre that his palsied brain and hands cannot grasp, presents a scene of dramatic pathos which could not have been realised without the wealth of detail which Mr. Fitzgerald decries.

Only in regard to stage-lighting are we at all in agreement with Mr. Fitzgerald, though this branch of stage art is not quite so advanced as the lecturer assumes. Still, when one considers the moonlight scene in "Herod," and the Agincourt scene in Messrs. Mollison & Waller's production of "Henry V.," there is every reason to believe that stage-lighting is receiving its proper share of attention in the development of stage art.

S. MARIA IN ORGANO, VERONA. SANMICHELI, ARCHITECT.

The Dowdeswell Galleries. WATER-COLOUR drawings by Mr. and Mrs. Harry Hine, of castles, abbeys and minsters, are now shown at these galleries. When artists are husband and wife the latter can seldom, if ever, be correctly described as the better half; and seeing the paintings of Mr. and Mrs. Hine together we feel, as might be expected, that the husbands are almost invariably better—more masterly, if one may say so. Distinction of line is a *sine qua non* when the subject selected is a building, or group of buildings, and this, more than anything else, is felt to be lacking in Mrs. Hine's paintings. But the difference is not, after all, so great as to justify our speaking of this as an undesirable partnership, and what remains to be said relates to the whole collection. They have travelled almost over England, not needing to be told that their buildings are beautiful, nor exactly what should be selected. The minster, passive, unchanging, but never the same to the painter—from dawn till the evening he works, and in this ever-changing climate he cannot have wanted variety. It should help architects to better their best to know that there are infinite possibilities of delight in buildings of every sort, and it is hoped that many may have opportunities of seeing, as they may here, in what esteem even the lowliest of their achievements are held by lovers of art, and by those who speak for them—the painters. They have gone as far north as Richmond in Yorkshire, as far south and west as Wimborne and Wells, and it is almost impossible not to feel envious. If the view of "Christchurch: Evening," is said to remind us of Albert Goodwin, it is because no praise could be higher; but there are drawings which stand alone in their excellence, suggesting no sort of comparison excepting with the spectator's ideal, and losing little or nothing thereby. Wimborne Minster, from the Meads; St. John's College, Cambridge—the well-known view from the "Backs"; Dunstable Priory; Pul's Ferry, Norwich; St. John's at Madder Market, Norwich; Hatfield House, from the Park; the Guildhall, King's Lynn, Norfolk—there is something in these that must deepen our feelings of reverence; and members of the many societies that have combined to oppose the spoliation of buildings hallowed by Time should spend a half-holiday here.

Plate Glass. PLATE glass, the creation of comparatively recent times, is responsible for many of the enormities which render the street architecture of to-day so devoid of grace and harmony. This subject has now become somewhat hackneyed, but despite all that has been said against the manner in which it is used, architects continue to emphasise the ugliness of their buildings by inserting great panes of what we know is a brittle, fragile material, and not therefore one to—apparently—support great masses of masonry and stone. It is always of special interest, in studying the development of architecture in any country, or part of a country, to note how local conditions govern the features of the style; and this is specially true of plate glass, though it would perhaps be too foolish to speak of the ordinary shop premises as being in a "style." There are those among us who are for ever harping on the despicableness of everything around them, and of the universal beauty of the work done by our forefathers. Doubtless there is much truth in their argument, but it helps us little in the effort to ameliorate our own conditions and improve our own productions; we are tired of their grumblings. Those, however, who contend that a house-window glazed with small panes—even those so popular at the beginning of the nineteeth century, about 12in. by 15in.—is much more pleasing in appearance than one glazed with one great sheet, are, we think, quite in the right. The work of cleansing is increased, it is true, but the slight additional trouble is well repaid. One cannot expect a modern shop front to be divided up into panes—nor would it be desirable perhaps—but a great improvement would be effected if the panes finished a couple of feet from the ground instead of running down to a thin brass rim on the pavement, being held vertically by an absurdly thin strip of brass or wood.

SANMICHELI AND HIS WORK.*

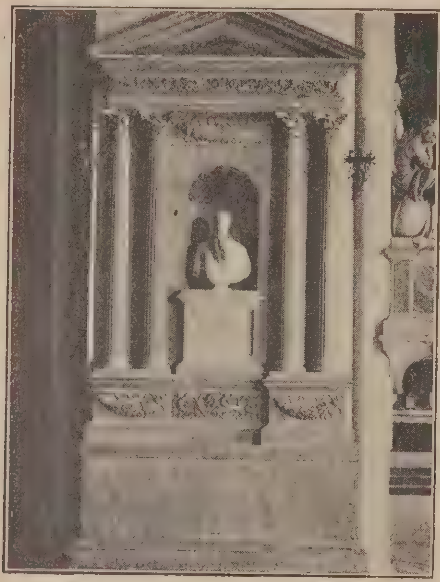
By J. STUART SYME.

IN taking up the study of the Renaissance architecture of Italy, or any particular phase of it, one comes face to face with a great conflict of opinions on the subject. There are those who condemn it more or less out and out, like Ruskin. There are those who revel in the fifteenth-century work of Florence and Tuscany, and such luxuriant examples as we find in the Certosa at Pavia. Some, again, fall down and worship the architecture of Michelangelo as devoutly as Mr. Fergusson the historian condemns it.

It is not proposed here to view the subject in the spirit which praises one phase of an art movement to the exclusion of all those others with which it is necessarily connected. It is suggested rather that we consider Sanmicheli and his work without prejudice to any admiration we may have for any other architect or school, whether of the Renaissance or not.

It might not be unprofitable to expend at the outset a few thoughts as to the questions which should have weight in an endeavour to determine the artistic worth of a man and his achievements. It is a question whether it is quite fair to accord our admiration, or the reverse, to an artist without considering the circumstances which helped to produce his art. We are, perhaps, a little inclined to lavish praises on an artist who produced specimens of his art which accord with our æsthetic ideas, and to overlook those circumstances of environment which, while shaping the road for our favourite, directed the energies of others in a direction in which it does not suit our humour to travel.

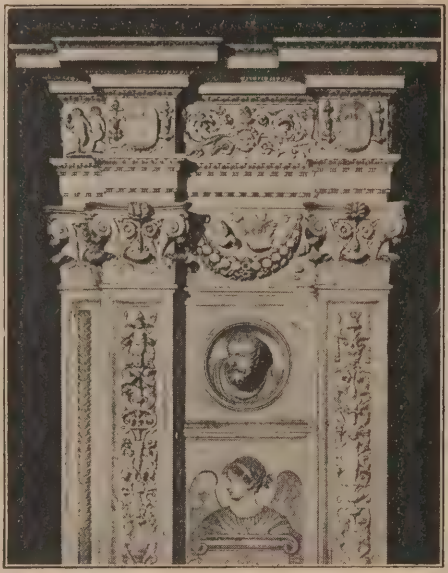
For instance, the delight which some of us may have in the Early Florentine work should not be allowed permanently to blind our eyes to the merits of the Early Venetian work, hampered as it was by Byzantine influences. If we, on the contrary, should be kindly disposed to this Byzantine feeling, let us not reject the other school which had no control of the circumstances which failed to equip it with similar material for inspiration.



MONUMENT TO CARDINAL BEMBO IN THE BASILICA OF S. ANTONIO, PADOVA. SANMICHELI, ARCHITECT.

We should, in fact, consider what favouring opportunities, or the reverse, an artist met with in the exercise and development of his art; and knowing them, we are in a better position to pronounce on the merits of his productions. Other thoughts as to the spirit in which such a study may most properly be made should doubtless suggest themselves readily enough to the student.

Let us look now at the outlines of the history of the Revival, and try to obtain some idea of the position in which Sanmicheli stood with regard to it. The beginning of the fifteenth century is generally understood to be the time which saw the birth of the Renaissance architecture of Italy, and to Florence is assigned the honour of being the cradle of the art. Filippo Brunelleschi may be said to have been the presiding genius of its infancy. It is interesting to note that the Revival sprang up in Florence, and not, as might have been expected, in Rome. Rome, however, at this time, owing to political disturbances, had fallen on evil days, and was even indebted to Florentine artists for the architectural productions of this period which it possessed.



DETAIL OF ALTAR, ORVIETO CATHEDRAL. SANMICHELI, ARCHITECT.

Here one may remark the confusion of ideas resulting from the use of the term "Roman" as applied to various matters that the student has to consider. For it may have reference either to the ancient classic art of Rome or to the art of the Renaissance as related to that city. Further, we may note that a Renaissance building of Rome does not necessarily show more traces of the ancient Roman influence than a building of the same period in one of the other great artistic centres. An instance of this might be shown in the facade of the Farnese palace at Rome, which has a feeling quite distinctly suggestive of the Florentine palace work of a century previous rather than of Rome's own ancient examples. Compare this with the Vecchian Library at Venice, which was erected nearly at the same time from the designs of Jacopo Sansovino the Florentine, and has a distinctly classic Roman character. One finds, naturally enough, some little difficulty in determining the influences which dominated the qualities to be observed in the works of the various architects of those times.

The Renaissance feeling, which first appeared in Florence, next showed itself in Milan about 1460, and in Venice about 1480. It was not until the beginning of the sixteenth century that the new influence made itself properly felt in Rome. Bramante, whose genius had been previously exercised in Milan and its adjacent territory, coming to Rome about this time, may be said to have been the pioneer of the new movement there.

Rome began early in the sixteenth century to reassert its position as a great centre of artistic activity, and here it was that the early Renaissance style, which may be said to have ended with Bramante, developed under the hands of his pupils and successors into what has been called the Culminating period. The influence of these followers of Bramante induced the spread of the classic forms of the late Renaissance all over Italy. It was to this Culminating period that Sanmicheli belonged. During this period a closer approach to classic Roman types was of course made, while the inspiration derived from the ancient examples was applied with greater boldness and facility than in the earlier work, and at the same time in a thoroughly sincere and intelligent manner.

It is surely not too much to claim for this work the place of first importance, inasmuch as the earlier work, however charming it may be, cannot be said to show the fullest development of the new ideas, while in that of the succeeding period (should we divide the Renaissance into three periods) we meet with the evidences of an inevitable decay.

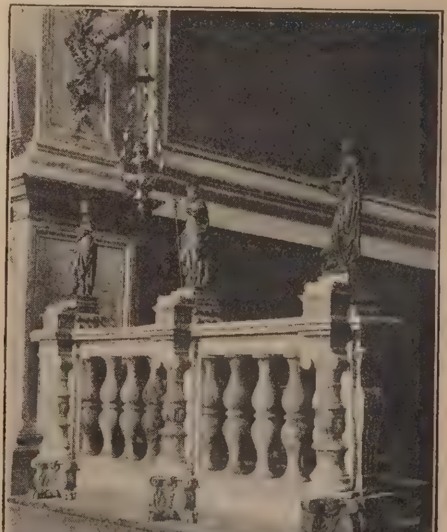
Sanmicheli's most important work was executed during this Culminating or central period, which may be said to be embraced, roughly speaking, in the first half of the sixteenth century; and though signs of the decadence of the art may be seen in buildings erected during our artist's lifetime, his work may fairly be said to be free from any trace of a downward tendency. In fact, the very essence of his art is an absolute negation of those same faults which in his contemporaries and successors led to the degeneration of what was noble and refined into the voluptuous and debased Barocco style.

Michele Sanmicheli was born at Verona, in the territory of the Venetian Republic, in the year 1484. His father was an architect, as was also his uncle, and from them he doubtless derived his first instruction in the rudiments of his profession. At the age of sixteen he went to Rome, and there commenced the study of the ancient architectural antiquities, measuring and examining everything with the greatest care and with a zeal which seems to have brought him into prominence not only in the capital but in the outlying territory also. It is worthy of note that it was just at this time that Bramante came to Rome, and that there had been up till then but little in the way of Renaissance buildings in the city. Sanmicheli would doubtless see springing up, in the course of the first few years of the new century, new buildings designed by Bramante, and of a more advanced type than he had been accustomed to. We may be sure that these new buildings, which included the Cancellaria and Giraud palaces, were carefully noted by our artist.

Sanmicheli's reputation as an industrious student of art seems to have procured for him the position of superintendent of works at the cathedral of Orvieto. For this building he designed the beautiful altar of the Magi, or Three Kings.

This piece of work has, as we might expect, a predominant early feeling about it, and some of its features suggest the early or Lombardesque manner of Bramante. The altar does not seem to have been completed at this time, as we read that Simone Mosca undertook the greater part of the sculpture work a good many years later.

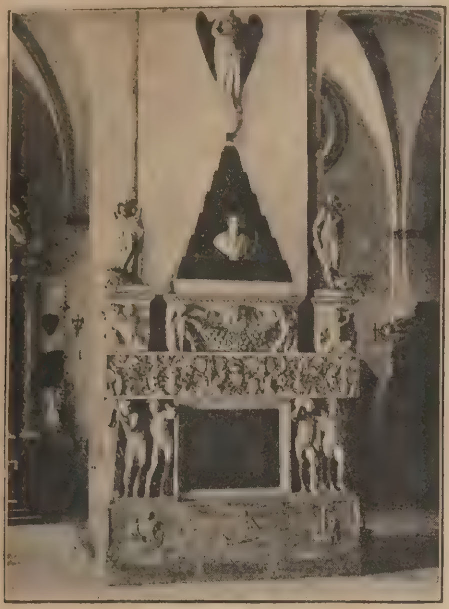
In the same town Sanmicheli constructed underground in the church of San Domenico a sepulchral chapel for the Petrucci family, as well as some houses here and in the neighbouring town of Montefiascone. The cathedral of this latter town, a church octagonal in plan



DETAIL OF CHOIR, S. GIORGIO, VERONA. SANMICHELI, ARCHITECT.

---

* A paper read before the Edinburgh Architectural Society on March 13th, 1901.



MONUMENT TO GENERAL ALESSANDRO CONTARINI, S. ANTONIO, PADOVA. SANMICHELI, ARCHITECT.

and having a cupola which is said to be of graceful and elegant design, is also attributed to him, though Sangallo the younger, who was certainly engaged in Montefiascone about that time, has also been credited with it.

The consideration of these works takes us to somewhere about the year 1523, which saw the commencement of the Pontificate of Clement VII. This pope soon found himself involved in the political disturbances which culminated in the sack of Rome in 1527. At the time of his election, the Emperor Charles V. and Francis I., King of France, were at war with one another in Lombardy; and Clement, apprehensive of the safety of his own territory, determined to strengthen the fortifications of the Ecclesiastical States. In particular, he wished to make secure Parma and Piacenza, two important towns in the north, close to the Lombardic frontier. Sanmicheli was appointed to assist Antonio da Sangallo the younger in the works just referred to, and by their labours the designs for the fortifications were brought to perfection.

This was the commencement of a long and eminent career as a military architect. For many years Sanmicheli must have directed his energies entirely to works of this class, and there can be little doubt that many of the characteristics of his style are the outcome of these years spent in the designing of structures in which utility was the consideration absolutely essential.

Sanmicheli probably completed his works in the north of the Papal States in the year 1526. Being at no great distance from Verona, he desired to visit his native town and to see once more his kindred and friends. Thither he went, and after a stay of a few days, formed a desire to examine some of the fortresses of the Venetian territory. Thus he made his way to Treviso, and after studying there he proceeded to Padua. The Venetians, who were at this time in league with Pope Clement VII. against the Emperor, being warned of this examination of their strongholds, and fearing that Sanmicheli might propose to use these observations to their injury, had him arrested and thrown into prison at Padua. Being assured however, on enquiry, as to his integrity, they immediately released him, and offered him a position in their service with the promise of a liberal allowance. Sanmicheli excused himself from accepting this offer on the ground of his being still in the service of the Pope, but he gave them fair promises, and was finally allowed to depart.

The Venetian Signori did not allow him to forget these promises, but seem to have brought all the influence in their power to bear on him, with a view to inducing him to abandon Rome and enter their service. Possibly they may have had some lingering doubts as to the object of his inspection of their fortresses. Sanmicheli, however, refused to stir until His Holiness accorded him full permission to depart, whereon he immediately set out for Venice and entered the services of the Signori within the territory of whose jurisdiction he had been born. This probably occurred either late in the year 1526 or early in the following year.

He immediately took in hand the works his masters had in view, and it was in Verona, his native place, that his abilities were first tested. Here, after overcoming many difficulties, he erected, to the great satisfaction of the Signori and their captain-general the Duke of Urbino, a splendid fort called "la Maddalene."

The erection of this structure may be said to denote an important development in the history of military architecture. Here it was that a new type of bastion was designed in which was realised a form which had hitherto been the aim of all mediæval military works. This aim was to provide a fortification which should give to the defences a strength and resisting power equal to the force of the attack up to the point where siege artillery acquired an irresistible superiority. The realisation of this is to be found in the angular bastion which Sanmicheli is credited with having originated.

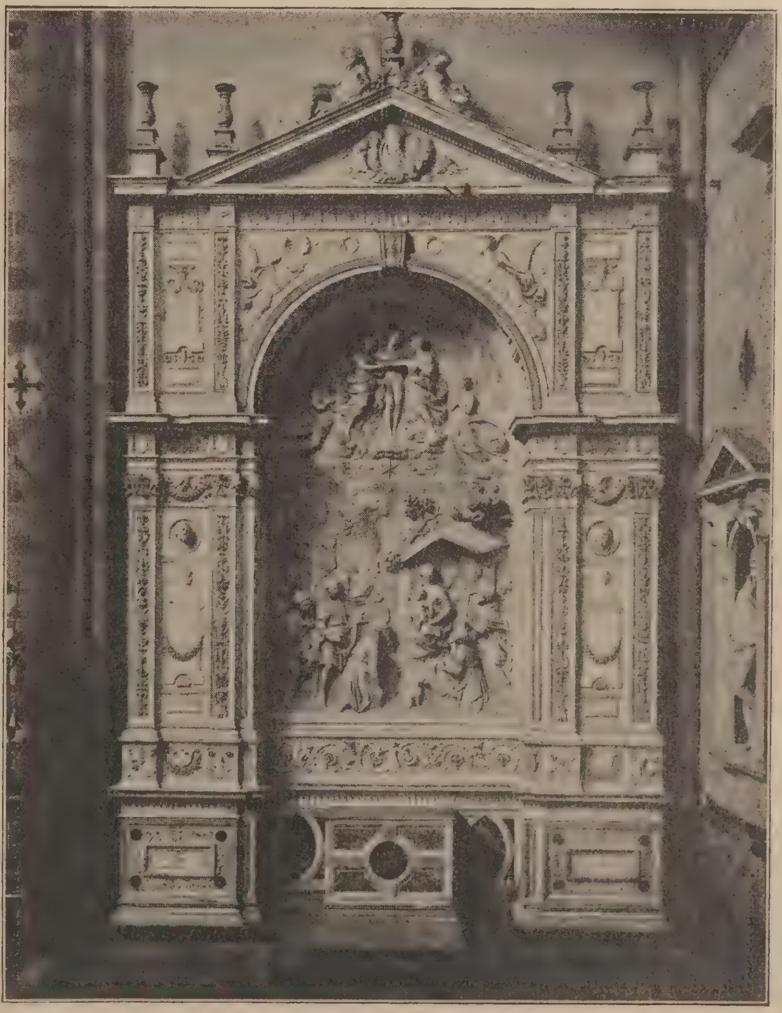
Viollet-le-duc, however, points out that France may reasonably contest Italy's claim to this distinction, inasmuch as there exists among the archives of Troyes a manuscript plan of fortifications for that town in which are clearly shown bastions whose faces form obtuse angles. This plan, Viollet-le-duc declares, cannot be of later date than 1530, at which time Francis I. had these fortifications repaired. It is quite possible that this form may have been evolved independently by different persons about the same time, as the military science of the day had been gradually advanced to a state of which this new departure was a natural outcome. These bastions were towers whose primary object was to defend the enclosing curtain wall of the fort, and they were attached to and projected from the wall at its salient angles and at certain intervals throughout its length. It was a maxim that "whatever defends should itself be defended." Thus these bastions relied to a great extent for their security on the readiness with which they themselves could be defended from points close at hand on the curtain wall. The early square towers and the circular ones in vogue later were deficient in this respect, for there was always a space in front of the tower which was not covered by the fire from the curtain on each side, and in this space the sapping or other work of destruction might under some conditions freely proceed. Later on a beak or horn was formed on the face of these round towers, by which means they were completely covered by the fire from the curtain wall, which would keep the enemy at a safer distance. The perfection of this idea is to be found in Sanmicheli's bastion, by means of which a perfectly complete system of defence works may be said to have been provided; for an assaulting column, whether it was thrown on a bastion or the curtain wall where a breach had been made, was always met by a cross-fire.

The faces of the bastions were defended not only by the fire from the curtain, but also by cross-fires from their own batteries; and so long as these batteries were in action any attempt to force a breach in the curtain adjoining was fully guarded against.

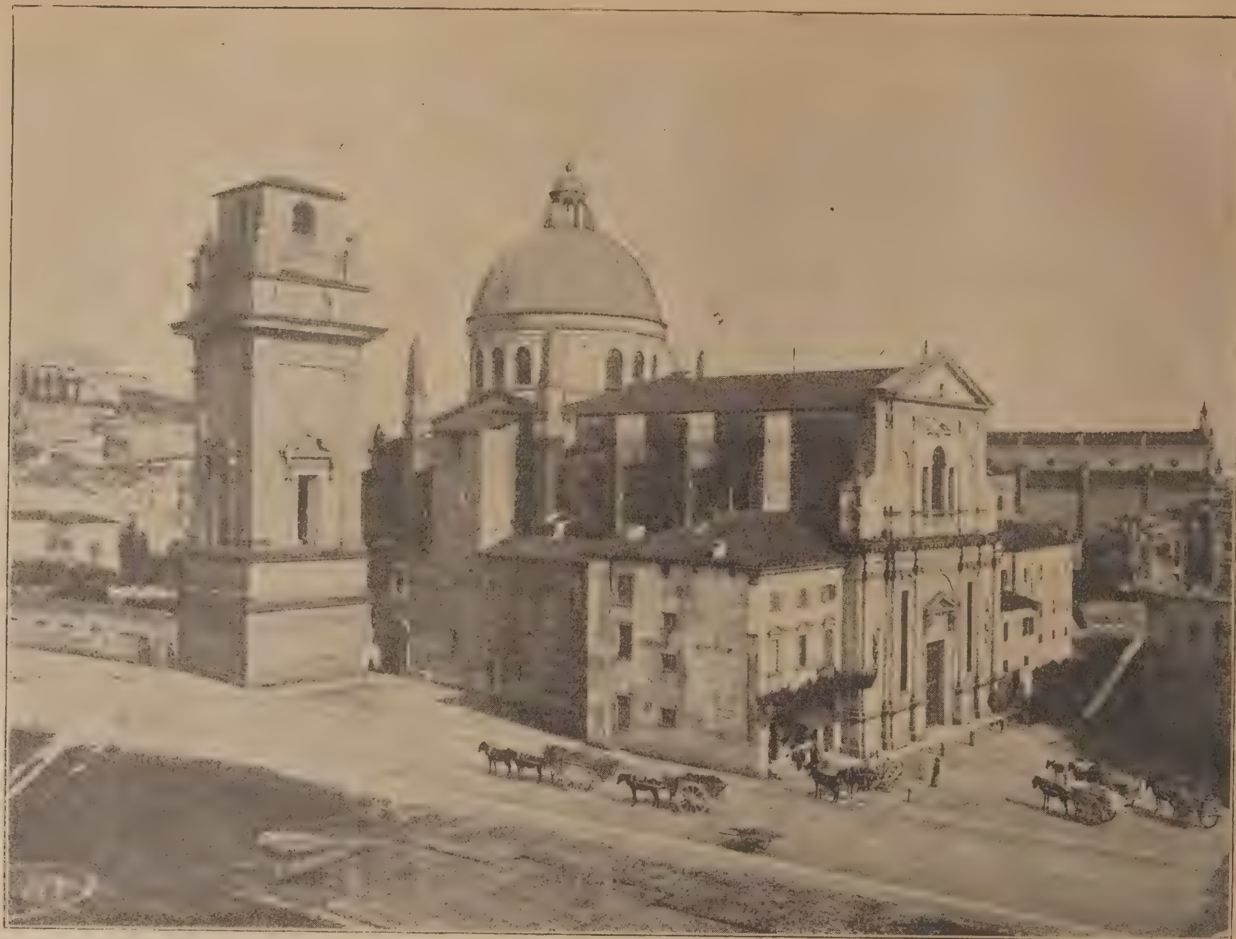
Further, should the bastion main batteries be silenced, a breach be effected in the curtain and an assault made there, the enemy were enfiladed by the fire from batteries held in reserve and masked from the fire of the siege batteries by the projecting rounded ends of the bastions, called orillons.

This, then, was the sort of work on which Sanmicheli was engaged almost exclusively for the best years of his life.

Fortunately, however, these fortification works, though primarily utilitarian, nevertheless afforded some opportunities for the display of artistic skill. These chiefly occurred in the fortified gates which gave access within the city walls. At Verona several gates were erected from his designs and these may be reckoned



THE ALTAR, ORVIETO CATHEDRAL. SANMICHELI, ARCHITECT.



S. GIORGIO, VERONA, SHOWING WORK BY SANMICHELI.

among the finest of his works. No praise, it seems to me, could be too high for the artistic skill shown in these productions. One is struck by the perfect fitness of the architectural treatment to the purpose which the structure was designed to serve. Here we have the two qualities which we should consider essential—simplicity and strength—expressed to perfection and with the utmost refinement.

The spirit of ancient Roman art seems to live again in them, and to justify the very foundation principle of the Renaissance. Few buildings of the period are clothed with forms which may be said to embody so entirely the letter of the old tradition, and yet here is given a manifestation of the most vigorous and healthy living art.

In the Porta del Palio a Doric order almost Greek in feeling is employed. The gateway is divided into three bays, with arched openings on the interior face, flanked by coupled attached columns, the whole face being rusticated. We note the immense keyblocks in which Sanmicheli delighted, and to which he gave a practical value in the actual support of the architrave. The entablature is beautifully detailed on regular classic lines. The columns have neither necking nor base, and the arches are denied an archivolt. The corners are finished with pilasters, not columns, and the horizontal rusticated courses are varied in depth. On the exterior front of the gate we have a richer treatment of a theme similar to the above. The order is employed with all its ornaments, and a flat arch is introduced under the architrave. The small side entrances are crowned with pediments carried on tresses.

In the Porta Nuova (illustrated on page 138 of the Builders' Journal for March 27th last) the same order is employed treated with the severest simplicity and with an effect that is most noble.

Sanmicheli also erected another gate in Verona, namely, that of San Zeno, and several bastions; much of this work is now destroyed. He also designed two fine gates at Legnano, and numerous other fortifications throughout the Venetian territories. So widespread, indeed, was his fame that he was begged to enter the service of the Emperor Charles V. and of Francis I., king of France, whose offers he was patriotic enough to refuse. The Duke of Milan was more fortunate in his endeavours to profit by the genius of Sanmicheli, as the obliging Republic his masters lent him for three months to their powerful neighbour. The late J. W. Anderson states this period at three years, but on what authority I know not.

So much was demanded of our architect that he had to depute a good deal of work, chiefly in the carrying out of designs, to his nephew, who seems to have been a very capable man. The only other work of this nature to which it is proposed to refer is the castle of Sant' Andrea del Lido at Venice. This was an undertaking of great difficulty, the site being, according to Vasari, a tongue of marshy land projecting into the sea. The Signori took good care to impress on Sanmicheli an idea of the importance of the work entrusted to him, and of the caution and care it would involve. He might well have undertaken the work in fear and trembling, knowing the despotic nature of the Signori, who seemed to favour that form of justice which consisted in hanging a man first and trying him afterwards. His contemporary Sansovino had a taste of their quality, being thrown into prison, degraded and fined 1,000 ducats because some stone vaulting in the library had fallen in during construction.

Sanmicheli, however, after tremendous effort succeeded in laying the foundations, which were below sea-level, and proceeded to erect a splendid fort. His difficulties were not over, however; for when the work was well forward, troublesome persons raised an agitation, alleging that the walls were not strong enough to sustain the weight of the artillery which the fort was to receive, much less the shock of its discharge. The architect immediately proposed that the fort should be armed with all the heaviest pieces of ordnance available, and that they should all be discharged at once. This was forthwith done, and the perfect solidity of the building was clearly revealed. Vasari quaintly remarks that such was the commotion raised by this incident, that certain noble ladies were removed from the city lest any catastrophe should have an ill effect on the delicate condition in which they happened to be at the time.

Now such a devotion to works of an essentially utilitarian character could hardly fail to have a marked effect on his designs for work where a more or less ornamental treatment was required. This view is, indeed, fully justified by the character of his civil and ecclesiastical works. The most notable example of this is the Palazzo Pompei at Verona, a work of great simplicity of treatment and most beautiful effect. The lower storey is rusticated, mouldings are to a great extent dispensed with, and a severe Doric order, almost Greek in feeling, is employed in the first storey. The broad archivolts of the upper windows, the huge keyblocks, and the raising of the columns on a double base may be noticed as characteristic of this architect's work. It should also be noticed that in this and his other buildings he simply recesses the joints of his rustications, and not the courses.

Besides the Pompei, he built many other palaces in Verona, including the Bevilacqua, Canossa, Guastaverzi, and others not readily identified (see Builders' Journal for February 6th last). Of these the most important is the Bevilacqua Palace, a building of some richness, in which we find again a rusticated lower stage. The Doric pilasters of this storey and the Corinthian columns above are grouped in pairs, which, with the windows they enclose, form main features of support, between which are large arched windows. Characteristic points may be noted in the keyblocks, the spiral flutings of the columns, and the double pedestals on which these are raised. A somewhat similar grouping of pilasters, and a window not unlike the small first-floor windows, may be seen in Bramante's Cancellaria Palace at Rome. An example of antique Roman columns fluted spirally is to be seen among the ancient ruins in Verona.

He designed in Venice the Grimani, Mocenigo, and Bragadini palaces, as well as some in other districts which are now lost to us. The Grimani Palace (see Builders' Journal for February 6th last) has been called Sanmicheli's masterpiece, though there are some defects in its proportions. Ruskin, who had little good to say of the Renaissance, spoke in glowing terms of it. It has some resemblance to the earlier Vendramini Palace, a work by Lombardi, who also came under Bramante's influence.

The Grimani Palace lacks the traces of the Gothic tradition noticeable in the earlier Venetian palaces, these being replaced by a strong Roman feeling. The arcaded bays in the upper storeys seem to have a suggestion of the Colisseum in their stunted proportions as well as their general composition. The unpleasing proportion of the upper storeys is the weak point in this design, the ground stage being perfect in itself. Sanmicheli's simplifying spirit finds expression in the use of one order throughout the facade.

We are told that the building had not proceeded very far at the time of the architect's death, and that his successors departed from the original details considerably.

The Palazzo Gran Guardia at Verona has been attributed to Sanmicheli, and also, with more show of reason, to a nephew who was evidently also a disciple.

With regard to ecclesiastical work Sanmicheli was singularly unfortunate. Notwithstanding the many designs he made for buildings of this class, there is hardly one that may be said to have been carried out in its entirety by him. The death of clients, scarcity of funds, stupidity of committees, and finally the death of the master himself, are responsible for this. The Pellegrini chapel, in the church of San Bernardino at Verona, is the most important work of this nature he has left us, and even this was not completed during the artist's lifetime. It is circular in plan, in the Corinthian Order, and shows detail of great refinement and grace. His works at Orvieto and its vicinity have already been referred to. Mention may be made of his works at Santa Maria in Organo, and San Giorgio, Verona, both incomplete.

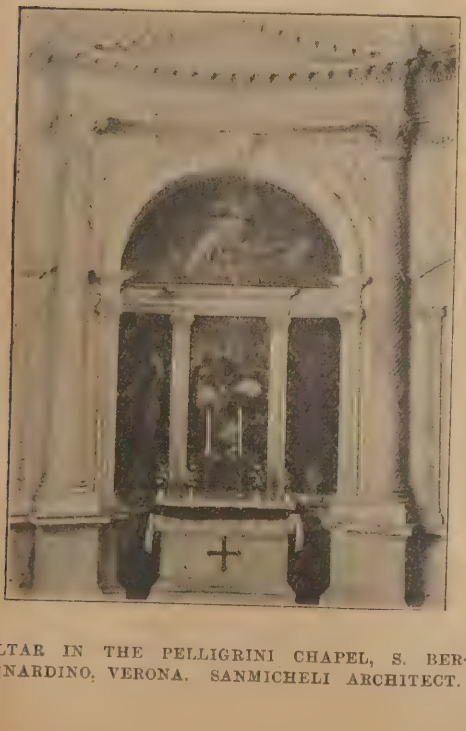
He designed, in addition, many other works of this class, which need not be referred to here.

Two interesting monuments which he erected are those at Padua to General Contarini and Cardinal Bembo. These are designed in a manner quite distinct from the well-known Renaissance type, which Sanmicheli is said to have considered more suited to an altar than a tomb, and to have objected to on that account.

There exists in Verona, and possibly also in other Italian towns, small works, such as doorways, attributed to him, which might be sought out and catalogued did a suitable opportunity for doing so occur.

A few words may be said as to the chief artistic qualities which Sanmicheli shows in his architectural designs. First and foremost are his great power of restraint, somewhat unusual in the artists of his time, and his love of simplicity. This power of restraint was, of course, inherent and natural; and his simplicity, though partly co-existent with it, was doubtless also the outcome of the particular circumstances under which his art was practised.

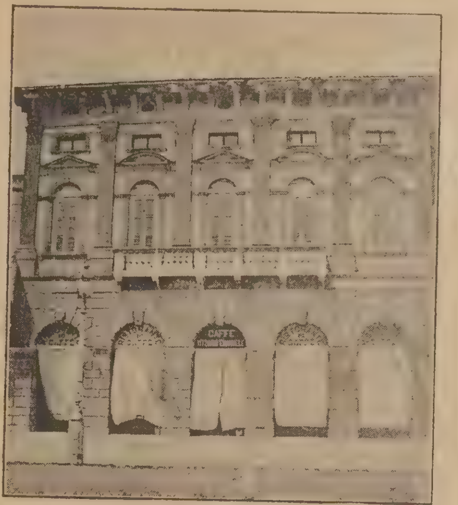
His devotion to works of military architecture, from which the idea of simplicity and boldness of treatment could hardly be separated, doubtless fostered this tendency of his. Another factor which may have led to his adoption of a simple treatment for his Veronese facades was the custom which held there and in other Italian towns of adorning them with painted decoration.



ALTAR IN THE PELLIGRINI CHAPEL, S. BERNARDINO, VERONA. SANMICHELI ARCHITECT.

In his ornate buildings we see his restraint very clearly, as well as in his severe ones. Compare his Grimani Palace, say, with Sansovino's Library at Venice, and one finds in the former a sense of repose which is somewhat lacking in the latter.

Sanmicheli seemed to have the faculty of giving to his subordinate features just the right amount of emphasis, keeping them in fact truly subordinate. A faculty closely linked to the above was his refinement. Even in his boldest semi-military work there is not a trace of coarseness. These are, in fact, but phases of his exquisite sense of proportion. He was possessed of great fertility of design and originality of treatment. Although he adhered closely to the elements of the ancient classic style, and probably received suggestions from the work of contemporaries, he developed them in a way peculiarly his own, and his compositions are varied, free from any taint of sameness and usually delightfully fresh. His Contarini tomb, highly satisfactory as it is from an architectural point of view, might well satisfy the cravings of the most earnest searcher for the original in art.

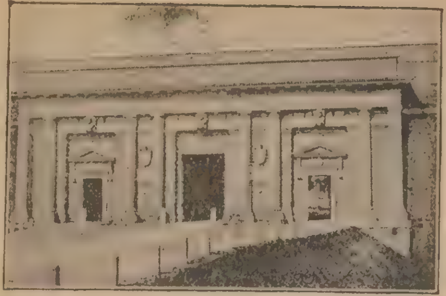


PALAZZO VERZI (GUASTAVERZI). SANMICHELI, ARCHITECT.

He gave great consideration in his designs to the connection which should exist between architectural features and the practical quality which they might be said to express. Thus his columns and pilasters are features of support, and not merely casual ornaments. The corners of his columnar facades he strengthened and finished with a square pilaster in a straightforward fashion, and they are always satisfactory. There is no quibbling with meaningless pillars, as in some of Sansovino's corners. His keyblocks, as their form suggests, were made actually to support the architrave which was jointed over them. We find him raising his columns on a double base, or even on a double pedestal, where he seemed to think the orthodoxy of a single base fatal to a proper expression of that feature.

A few words may suffice to tell of his personal characteristics, which were indeed in perfect harmony with the refined artistic qualities of the man. Judged in the light of the contemporary standard of morality, he seems to have been well-nigh perfect. Vasari says he was a man of most orderly and upright life, highly honourable in all his actions. He was a man of most devout and religious habits, and most careful to perform his daily religious exercises before attempting to start work of a morning.

A contrast to this sober regularity may be found in Michelangelo, who threw himself on his bed at nights dressed just as he was in his working garb, and after a few hours rest would rise impatient to be at his beloved work. So careless is Michelangelo said to have been that parts of his clothing were sometimes unremoved for weeks at a time, with the result that when that necessary operation was performed his skin suffered considerably in the process.



PORTA STUPPA, VERONA, SANMICHELI, ARCHITECT.

Sanmicheli was generous almost to a fault. If we may believe Vasari, he was the most kindly and friendly man that ever lived, insomuch that he was hardly aware of the wants or desires of his friends before he would instantly set about labouring to fulfil the same, though it were to the spending of his life. We are told that the Venetian Signori many times desired to increase his stipend, but that he always declined these addditions, desiring that these sums should be given to his nephews, who assisted him in his work. Vasari gives many instances of Sanmicheli's liberality and courtesy, which show well in the light of the character of such a man as Torrigiani the sculptor, who, it is said, used to boast that he had broken Michelangelo's nose in a fit of anger. This sculptor, however, carried his passion for breakage a little too far; for in later years, having a dispute with a Spanish grandee about the price of a Madonna he had carved, he dashed the sculpture in pieces. For this sacrilege Torrigiani was promptly thrown by the Inquisition into prison, where he starved himself to death.

Sanmicheli was, in fact, highly esteemed by many of the great men of his day, by artists and nobles alike. Michelangelo, in particular, is said to have had the greatest regard for him. He died in Verona in 1659, at a good old age, and was buried in the church of San Tommaso.

His work, without doubt, had a good influence on the art of his contemporaries; and to successive ages of architects it has stood as an example well worthy of study, and a safe guide to those who desire to express their art with dignity, sincerity and refinement.

AREA LIGHTS.

PROPOSED RESTRICTION AT SHEFFIELD.

THE secretary's report read at the recent annual meeting of the Sheffield Society of Architects (see page 199 of last week's issue) referred to the question of area lights. A letter had been sent to the Town Clerk in regard to the proposed action of the Plans Sub-Committee of the Highways Committee to restrict the construction of area lights in footpaths. The letter pointed out that up to the present the Society had no intimation that area lights were objected to by the Corporation, and they were unable to ascertain that any resolution had been passed by the Highways Committee of the City Council in regard to this matter. They considered that some formal intimation should have been given to the architects of Sheffield before the Corporation changed their policy. The proposed prohibition of area lights was a serious matter, affecting the value of property, both to owners and ratepayers of the city. The prevention of area lights would depreciate the value of building site already acquired on the supposition that such light would be allowed, as previously had been the case, and it would considerably reduce the ratable value of the property. Area lights of the maximum projection, if properly constructed, constituted no danger or inconvenience to the public, and most of the important towns allowed them to be constructed under proper regulations. This had been considered by the Highways Committee, and referred to the Works Sub-Committee, upon whom a deputation from the Society had attended. The sub-committee had delegated the chairman, vice-chairman and City Surveyor to meet the deputation at a future date and discuss the matter in detail.

THE QUEEN VICTORIA MEMORIAL.

SOME FURTHER OPINIONS.

We published last week a synopsis of the opinions of leading architects, sculptors and designers on the National Memorial to Queen Victoria to be erected in front of Buckingham Palace. Since then some further opinions have been expressed in the daily press.

Mr. Walter Crane

Mr. Walter Crane writes to the "Daily Chronicle" supporting the contention that the memorial should be the subject of an open competition among the artists of the country. In his opinion the general scheme should be sufficiently comprehensive to need the co-operation of many artists, including architectural and decorative design, as well as portrait and allegorical sculpture, and the work of many cunning craftsmen.

He says: "In the realisation of such a monument in the present condition of public taste, it seems to me there are too main pitfalls. On the one hand, there is the danger of sinking into tameness, and on the other of breaking out into extravagance and vulgarity.

"Such a thing might be made as official and characterless as our postage stamps, or some of our coinage; or as flamboyant as the latest steel-framed street frontage playfully concealed in terra-cotta, and, perhaps, 'surmounted by something Japanese.'

"It seems to me, too, that a mere naval and military trophy, however imposing, would be inappropriate. It is rather in the arts of peace that we have the most honourable record during the last sixty years, and it is by our progress in these that we shall be remembered in the future."

And His Suggestions.

Mr. Crane suggests that, in the open competition, "a certain number of prizes might be offered, so that meritorious designs not winning the first place might still have some substantial recognition and the designers some reward for their labours. A public free exhibition should be held of all the designs sent in, and the public invited to record their vote, by ballot, of the one preferred. Models to scale should be sent in by every competing artist of his design, and the models should be all to a given scale.

"Another way of obtaining a fairly extensive national opinion on the subject would be for each leading newspaper to invite its readers to send in the names of, say, five or six artists (to include architects, sculptors, and decorative designers) whom they would prefer to be invited to design the memorial. Then those artists whose names had the majority of votes should be invited to form a committee or council to draw up a scheme for the memorial and assign the execution of its different parts, which should be distributed as widely as possible, so far as might be consistent with excellence of design and workmanship."

Mr. Philip H. Newman's Walhalla.

Mr. Philip H. Newman, the honorary secretary and treasurer of the Society for the Encouragement of the Fine Arts, also writes to the "Chronicle" on the subject. He thinks that a building in the nature and scope of a Walhalla might be erected on the site of the transept of the Exhibition of 1851. In his opinion it might be even preferable to any other scheme, not only because of the possibility of including in some part of the plan the present Albert Memorial, but because "a building would afford that shelter to the groups and statues adorning it which our climate and London's atmosphere peremptorily demands."

What the Committee had in View.

Among the schemes considered by the Executive Committee was the revived one for extending Westminster Abbey as a national Walhalla, by adding a new chapel to it. Another was the erection of a building which should be of such design internally and externally as to typify Queen Victoria's reign. It was urged in objection to the latter scheme that the building would have to be in one of the parks, and so out of the way. Accordingly, in the end, the proposal for making the Mall into what may be called a "triumphal avenue" was adopted.

The view of those charged to decide the matter was that the Mall memorial would be more a question of sculpture than of architecture. It was necessary that a bird's-eye plan, so to speak, of the whole scheme should be made by an architect, but after that it would be the sculptor chiefly who would be called upon. It was decided to ask Mr. Brock to design the chief group of sculpture, that to be set up near Buckingham Palace. This was to be a beginning, for it was clearly understood that our other leading sculptors would be asked later, as funds justified progress, to contribute sculptures for the adornment of the Mall.

That point is important as removing a misunderstanding. The argument based upon it is that the memorial will really be open to the work of all our best sculptors. As to the task of the architects, the contention is, as has been stated, that it is subsidiary to the other.

These observations may be taken as indicating, more or less, the view of those charged with the organisation of the Memorial.

Mr. Caröe objects to the Mall Scheme.

Mr. W. D. Caröe said to a "Chronicle" representative: "I don't like the Mall scheme at all. I don't think it will work out well. At one end of the Mall you have Buckingham Palace, which can hardly be called a thing of beauty. At the other end you have the new Admiralty buildings, which are not beautiful either. Then, I think, it's a pity to interfere with the Mall, which has many historial associations, more especially as better schemes are possible. My own favourite one, perhaps, is the extension of Westminster Abbey, but various excellent schemes might be suggested." With regard to the question of a limited or open competition, he thinks that the greater the available talent the better.

Mr. Wimperis's Censure.

Mr. Edmund Wimperis, the well-known architect, holds strong views on the subject. Speaking of the Committee's action to a "Chronicle" representative, he said: "They say the best men will not send in competitive designs. Can they prove this? I have the very best reasons for knowing that it is not so, and that if there were a competition every one would send in designs. In my opinion the committee have gone on the wrong tack altogether. They begin by asking for a statue of Queen Victoria, and making that the central point of the whole memorial. And then they go on and ask the architects to provide the statue with some sort of a resting-place. What they might have done was to have asked for designs for the memorial as a whole."

Nothing New under the Sun.

A curious fact is made known by Mr. T. May. He finds that the suggested avenue from Buckingham Palace through the park, with an outlet by way of a memorial arch, is exactly paralleled in an engraving published on May 12th, 1794, by Lawrie & Whittle, of 53, Fleet Street, illustrating the Grand Walk in Vauxhall Gardens, with triumphal arches and statues of Mr. Handel and other famous musicians. Solomon was always wise in his sayings.

Mr. Adams Acton wants a Statue 200ft. High.

We learn that Mr. Adams Acton, the sculptor, recently submitted to the King a scheme which he has for the Victoria Memorial. By the King, who no doubt has been made the recipient of many suggestions, it was passed on to Lord Esher, the secretary of the Victoria Memorial.

Mr. Adams Acton designed the model for a statue 200ft. high. The design shows the Queen in her coronation robes. The sculptor would make the interior space of the monument, furnished by a colossal pedestal, a treasure-house for memorials of Queen Victoria's reign and a Walhalla for our illustrious dead. From the topmost jewel of the Queen's crown a great light would radiate at night, and lesser lights from the other jewels.

Mr. Adams Acton adds that if the scheme were carried out in its entirety it would give employment to all our leading sculptors and architects. Engineers would also be needed in the construction of the monument.

Mr. Lennox Browne makes the suggestion in the "Daily Graphic" that the Palace might have another storey added to it, a central cupola erected, the stucco removed from the front and replaced by red brick and stone, and a great curved screen with arches of varying heights substituted for the existing railings. Outside this screen, and facing the Palace, would be the statue of the late Queen on a high pedestal.

A special meeting of the Royal Institute of British Architects is to be held shortly to discuss the whole matter of this memorial.

THE BRIDGES OF CARDIFF.

An article on "Bogey Bridges of South Wales," by Mr. Edwin Seward, F.R.I.B.A., recently appeared in the columns of the "Western Mail." In Queen Street, Cardiff, the Taff Vale Railway Company some years ago cleared away a heavy, grimy, and undesirable structure of stone, replacing it by a girder bridge of a character "which, though not, perhaps, fulfilling all æsthetic requirements, goes a good way towards being an example of how iron girder bridges can be shaped and brightened up. The adjoining Rhymney Railway bridge has always been among the more graceful pieces of engineering design in the locality. Elsewhere in the town, however, another aspect of things prevails. The bridge carrying the Great Western Railway over Bute Street remains an utter disfigurement, with its uncompromising iron plates and girders. Another unsightly structure is the gloomy, tunnel-like bridge under the Great Western Railway in Penarth Road.

"In the matter of river bridges Cardiff is more fortunate. The widening of Cardiff Bridge itself (always regarding it as a modern engineering addition to an old masonry structure) is more broadly and attractively dealt with than is often the case. Cardiff is again fortunate also in having an engineering work of great technical importance and almost unique design in the Clarence Bridge over the Taff.

"Burges's little galleried bridge of Swiss character in the grounds of Cardiff Castle is most worthy of mention.

"On this subject of local bridges, considering the coming development of Cathays Park, it looks as if the long-expected highway from a point in Cathedral Road across the Taff and canal towards Cathays would afford an excellent opportunity for good designing. Perhaps a Victoria memorial may be asked for in connection with Cardiff, and, with the Clarence Bridge crossing the southernmost passage of the Taff, a Victoria Bridge connecting the northern districts above referred to would be a suitable and useful and (as it should be) a beautiful memorial to her late Majesty."

NOTES ON AN ARCHITECTURAL TOUR IN BELGIUM.

This was the title of a paper by Mr. James A. Arnot read before the Edinburgh Architectural Society recently. Belgium, although a small country, said Mr. Arnot, was exceedingly rich in architectural monuments. Its historical record is no less interesting. It attained the height of its prosperity during the Middle Ages, but declined under the tyranny of the Spanish rule during the fifteenth century. The country was not famous for its ecclesiastical architecture so much as for its splendid array of buildings devoted to secular purposes. Evidences of this wealth of the country were to be seen in the town halls of Brussels, Bruges, Ghent, &c., which were most richly adorned with sculpture and detail. Among the trade and guild halls were also to be found buildings of no mean importance. The most notable of this class were the cloth hall at Ypres and the halls at Bruges. Among the guildry houses at Brussels and Antwerp were also seen traces of the wealth of the country.

In domestic buildings the people displayed the same care that they gave to more important edifices, and in this class were found many interesting facades richly adorned with brick tracery and cusping. Among buildings of the present day the most important was the Palais de Justice, Brussels, which ranked amongst the world's wonders. At the present time there was in Belgium a tendency to adopt the style which has become known as "L'art Nouveau," and whatever the merits or demerits of this break away from the beaten track, it was a subject well worth studying, as it was undoubtedly the outcome of very considerable thought.

UNION BANK BUILDINGS, ABERDEEN.

CONSIDERABLE improvements have been completed to the Union Bank Buildings in Castle Street, Aberdeen. By the reconstruction now carried out there is both an outer and an inner door to the telling-office, so that all draughts are avoided. The architectural features of the outer doorway are pilasters and architrave. An entirely new polished mahogany doorway and porch have been provided, the larger outer door sliding back into a pocket. The inside double swing doors have bevelled plate glass panels in the upper portion. Inside the office a new mahogany counter has been provided, with circled glass framing for the teller's boxes, and space provided for four instead of three tellers as formerly. The floor of the office has been laid with mosaic tiling of a unique pattern, the bank's coat of arms—a combination of the arms of Edinburgh and Glasgow—being wrought out in the centre. The whole office has been re-painted and re-decorated by Messrs. A. Ferguson & Co., Aberdeen, whose design was selected in competition from those submitted by the leading painters in the city. The present building was erected in 1800, for the Aberdeen Banking Company, from plans by Mr. James Burn. Electric light, electric bells, and telephones have been introduced. A patent collapsible iron gate, furnished by the Bostwick Gate and Shutter Company, London, shuts off the bank offices proper from the access to the dwelling-house. The grill in the arch over the entrance door is composed of Scotch thistles wrought in hammered iron, with the name of the bank intertwined, and was executed by Messrs. Jones & Willis, Birmingham. The outside iron gate of the doorway was provided by Messrs. David M'Hardy & Son, Netherkirkgate, Aberdeen; the woodwork by Messrs. M'Robbie & Milne, Aberdeen; the masonwork by Messrs. Gall & Walker, Aberdeen; the electric lights by Messrs. Pratt & Keith, Aberdeen; and the tiling by Messrs. Carter & Co., Poole. The counter brackets between the tellers' boxes were constructed by Messrs. John Blaikie & Son, Aberdeen. The architect for the work was Mr. A. C. Bruce, of Messrs. William Henderson & Son, Union Street, Aberdeen.

PALAZZO GRAN GUARDIA, VERONA; IN THE STYLE OF SANMICHELI.

PRESTON ROYAL INFIRMARY.

A SCHEME of alterations and additions to the Preston and County of Lancaster Royal Infirmary, including the erection of a new operating theatre and the addition of a new wing to be used as a nurses' home, is being carried out. The new operating theatre has already been completed, and is now in use. With the furnishings, it cost £2,654. It consists of a room for the reception of patients, anæsthetising room, operating theatre (lighted from the roof and sides), doctors' consulting room, lavatory, &c. With a view to guarding against the lodgment of dust and a harbourage for microbes these rooms have been laid with tiled floors on concrete, the walls and ceilings tiled throughout, and all corners rounded off. The operating theatre has a semi-circular end. The semi-circular ceiling is surmounted by a second roof to admit of an equable temperature at all times of the year, while large windows of polished plate glass, obscured on one side, give a bright and even light. The natural system of ventilation—heating by radiators specially constructed for easy cleaning—has been introduced here. A special feature has been made of the drainage, the waste pipes being disconnected from the drains, and the sinks and other surgical apparatus being of the best quality. The theatre is electrically lighted by brackets from the sides, and there are five movable lights round the operating table.

The new Diamond Jubilee wing, which joins up to the present administrative block, is intended as a nurses' home. It consists of 43 bedrooms, bathroom, large nurses' day room, large nurses' dining-room, linen rooms, sitting and dining rooms for head nurses, probationers' and other accommodation.

Alterations have been effected in the children's ward, the covered way, the typhoid block, and the main wards. In the children's ward there is a new bathroom, and the wards, corridor, kitchen, bathroom, and other offices have been been laid with terrazzo flooring, and the walls have been tiled, while the whole building has been painted and redecorated. The latest sanitary fittings have been introduced, and the drainage has been rearranged, while the system of heating has been improved. All skirting, cornices, and all square internal angles have been removed and made concave, to allow of easy cleansing. In the typhoid block renovations and improvements similar to those in the children's ward have been made, and this also applies to the alterations now proceeding in the main wards. The ventilation, which is on the natural system, has been carefully considered, and special arrangements are being made for the summer, when the movement of air is sluggish. Electric light will be introduced. The heating arrangements are also being remodelled, while the entire system of drainage is being rearranged, as the old system was considered far too defective for a building of this nature.

Further additions, are in contemplation. Plans have been prepared for a new out-patients' department at the side opposite the new nurses' home, and when completed this proposed new wing will balance the one already in progress, the entire block then taking the form of a cross. In this proposed wing there will be provision for a large central waiting room, with consulting rooms, surgery, and dispensary, and an ambulance porch. Alterations to the administrative block which will give improved conditions and increased facilities are also proposed, and several other necessary changes in the lesser departments are also to be introduced. All of this work of alteration and addition has been carried out from plans prepared by Mr. F. E. Dixon, A.M.I.C.E.

SCENIC ART.

The Architecture of "Coriolanus" and "The True Principles of Stage Scenery."

A VERY interesting interview with Sir Laurence Alma-Tadema with regard to the architectural scenery in Sir Henry Irving's "Coriolanus" at the Lyceum Theatre was published last week in the "Daily News." Sir Laurence, it may be mentioned, has a very fine collection of architectural photographs of buildings in all parts of the world.

"Coriolanus," he said, "presented difficulties far beyond the other plays for which I have designed the backgrounds. In the first place, our accurate knowledge of such a distant time is necessary very limited. In the second place, what we do know places serious obstacles in the way of presenting that dramatic contrast which is so essential in the theatre. For the information which the discovery of the monument beneath the Lapis Nigra afforded proves almost conclusively what, indeed, was known before, that the early Roman civilisation was mainly Etruscan.

"But it was necessary in this play to mark a contrast between the inhabitants and the buildings of Rome and Corioli, and to make the Rome of Marcus more distinctively Roman, and I was obliged to avail myself of a little artistic or poetic licence. In the Volscian scenes I have made some attempt—necessarily founded largely on conjecture—to reconstruct the known characteristics of Etruscan architecture. In the Roman scenes, while partly preserving the same character, I have allowed myself a little latitude in bringing the date of the play in architecture a little nearer to a period which can be recognised as definitely Roman, while I have sometimes assumed that the earliest forms in furniture and other accessories were not so far different in earliest Rome than in earliest Greece—as who shall clearly differentiate the forms of common things in the beginning of the two civilisations?"

Sir Laurence's water-colour originals for the interior of Caius Marcius's house, and the beautiful exterior of Aufidius's house in the moonlight, are to be exhibited at the Water-Colour Society's gallery this year.

Mr. PERCY FITZGERALD'S PAPER.

Mr. Percy Fitzgerald read a paper on "The True Principles of Stage Scenery" before the Society of Arts last week.

Formerly, he said, it was the drama, with the display of character and emotions, that constituted the attraction on the stage. Now panoramic and spectacular joys were provided, and there were fair grounds for the general opinion that in this direction we had all but reached a sort of perfection.

But this extraordinary circumstance had to be noted—the whole of our scenic system seemed based on a number of primitive shifts and devices, clumsy to a degree. Trees were supported by means appropriate to music stands; rocks were boxes with painted linen tacked on; the sky was represented by strips of linen suspended from sticks, like clothes hung out to dry; landscapes fluttered about foolishly; and from the stalls you could see great disillusioning gaps.

He did not know what was gained by the modern built-up scenery. No dramatic advantage was secured by making people ascend or descend flights of steps, or cross bridges, or enter the porch of a church, as all those operations could be described or suggested. "It may seem paradoxical to say so," continuted Mr. Fitzgerald, "but it seems that the greatest so-called improvement of modern days, namely, the brilliant lighting of the stage, has done much to destroy all scenic illusions." Many would recall the beautiful scene-painting of Tolbin, Stanfield. Grieve, and Danby, and of Mr. Craven in his earlier days. Formerly scene-painters became R.A.'s—a thing nowadays inconceivable.

The scene-painters of those days were able to produce such finished work because the light on the stage was low and did not kill their colours. At the present time all half-tone yellows and other delicate tints disappeared, and the painters had to paint to suit the conflagration. In Garrick's days there were simply four large chandeliers, which furnished a zone of light within which the actors kept, the rest of the stage being misty, and the surrounding scenery much like the indistinct details of the tapestry.

We were not working on the right lines—we were engaged in thoroughly disillusioning audiences. Scenery, he argued, should be more or less abstract, for "if the interest excited by the dramatic situation be sufficiently strong and overpowering, we shall not note how the players are dressed, or how magnificent the scene and its appointments are."

Correspondence.

Computing Land Areas.

To the Editor of THE BUILDERS' JOURNAL.

LONDON.

SIR,—I read with interest the article in your issue of April 10th on the above subject, and should like to make one or two remarks respecting the concluding paragraph.

Alluding to the computation of areas contained within irregular boundaries, the writer observes that "no method of computing curved outlines can be considered as absolutely correct," from which remark I am led to conclude that the writer of the article is not familiar with the great advantages to be derived from the use of Amsler's planimeter for this purpose; since, by the use of that instrument the difficulty alluded to is entirely obviated. Sir Frederick Bramwell, in a communication to the British Association (printed *in extenso* in the Association's Report for 1872), pointed out that the area of any figure, *however irregular*, can, by means of Amsler's planimeter, be measured with "absolute accuracy" by merely running the tracing point of the instrument round the perimeter of the figure to be measured; and stated that "it gives to the surveyor the readiest means of calculating the acreage of whole estates or of separate fields."

Of the various methods for computing land areas from maps and plans, that in which the planimeter is used is, I feel confident, by far the simplest and most accurate; and were this fact more generally known other methods would be discarded in its favour. The planimeter records the number of *square inches of map surface* contained by the plot under measurement, and if this and the scale of the map be known, it is clear that the acreage of the plot can be calculated. To do away with the necessity for these calculations, I drew up, a few years ago, some tables, showing—for any scale—the area in acres, roods and perches represented by any number of square inches of map surface, which thus form a "Ready Reckoner," from which the acreage can at once be taken. Having been requested to make these tables available for public use, I lately submitted them to the well-known firm of E. & F. N. Spon, Ltd., who published them.

I should like to add that I do not think it is overstating the case to say that the combined use of the planimeter and these land area tables reduces the labour involved in the computation of areas to a minimum, as no previous knowledge or practice is required, and the work can be performed by the most unskilled person. —Yours truly, WILLIAM CODD.

Little and Great Stanmore Churches.

To the Editor of THE BUILDERS' JOURNAL.

LONDON, N.W.

SIR,—May I venture to correct an error made by "G. A. T. M." in his reply, on page 203 of your last issue, respecting Little Stanmore Church. The church described in the answer is that of Little Stanmore *alias* Whitchurch. The ruined brick church to which the query refers is that of the adjoining parish of Great Stanmore.

The original church at Great Stanmore stood on a site about a quarter of a mile to the south of the ruined brick church. Its position was denoted by a tomb to the memory of Baptist Willoughby, who was for fifty years incumbent of the parish, and died in 1610.

In 1632 a new church was built on a site given by Mrs. Barbara Burnell, Sir Thomas Lake and a Mr. Robinson. The building was erected at the expense of Sir John Wolstenholme It was consecrated by Bishop Land (afterwards Archbishop), and dedicated to Sir John the Evangelist. The building consisted of a nave and chancel, with an embattled tower at the west end. The porch, which apparently stood on the south side, was designed by Nicholas Stone. The arms of the Wolstenholme family were introduced into the glazing of the east window.

In 1720 six bells from Little Stanmore church were bought by the parishoners, and were hung in the tower. The church contained memorials to the Drummond, Wolstenholme, Burnell and Beauclerk families, and a vault belonging to the Marquis of Abercorn. The vault referred to in the query is probably the mausoleum of the Holland family, formerly of Stanmore Hall.

The present church, which stands to the east of the second church, was built about 1849. Mr. Henry Clutton was the architect. It contains several monuments, which were removed from the previous building; among them being that to Sir John Wolstenholme, which was designed by Nicholas Stone, and cost £200. Another monument to John Burnell, his wife and family curiously represents three children who predeceased their parents, holding skulls in their hands. The parish register dates from 1599.

"Twopence a Week" will find references in Lyson's "Environs of London" (1810), a copy of which at the Guildhall Library is extended from the original four volumes to thirteen volumes by the insertion of engravings. Hughson's "London," published also in 1810, and Cassell's "Greater London" also contain notices of the church.—Yours truly. B. C. DEXTER.

Builders' Notes.

Building Operations at Cambuslang.—To cope with an ever-increasing demand for shops and houses, especially of two and three room apartments, building operations have been exceedingly brisk in Cambuslang for the past few months. The large blocks of tenements at Pretoria Street and Park Street are rapidly nearing completion. A line of shops is to be commenced at Tavern Square. Brownside Road and Greenlees Road have lately been lined by many self-contained cottages.

A Private Chapel in the new Archiepiscopal Palace at Canterbury was consecrated last week. The chapel has been erected, from designs by Mr. W. D. Caröe, architect to the Ecclesiastical Commissioners, by Messrs. John Barker & Co., of London, contractors for the alterations and additions to the palace. There are two rows of stalls on each side of the chapel, which, like the panelled roof, are carved in fumigated oak, and on the ends of the stalls are figures of the archbishops from St. Augustine to Dr. Benson.

Mr. Henry William Bull, head of the firm of Bull & Sons, builders of the Law Courts, the Parliament Houses at Cape Town, and other large structures, died at Southampton last week. It was during the work at the Law Courts that the famous masons' strike occurred. Mr. Bull went to Germany and engaged a large number of German masons, whom he brought to England, and they were housed on the site of the Courts under Government protection. The building operations ruined the firm, and a claim of many thousands of pounds on the Government for extras is still unsettled.

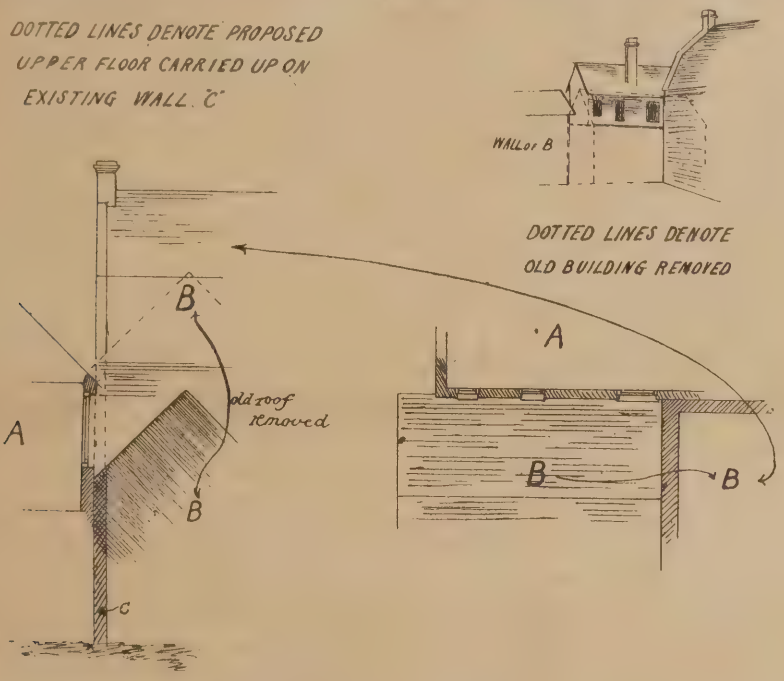
"How is the Future Workman to be Trained?" was the title of a lecture delivered by Mr. George Ellis before the members of the British Institute of Certified Carpenters recently, at Carpenters' Hall, London Wall, E.C. The lecturer advocated the establishment of numerous apprenticeship schools, organised and managed by a joint committee of masters and men, to which boys should be indentured for a term of years. The first year should be spent entirely in the workshop of the school, and the succeeding years partly in the works of the affiliated firms and partly in the school. This would enable the boys to be trained rapidly both in theory and practice. The cost of maintaining the schools could be met by contributions of the employers, local taxation, and the premiums paid by the parents of boys apprenticed.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Ancient Lights.

Potton.—W. H. R. writes: "I should be glad of your assistance on a question of ancient lights arising as follows:—Owner of property B has pulled down one-storey building (see accompanying sketch), with the exception of wall C, intending to carry that up for a new bedroom (see dotted lines). The removal has revealed bedroom windows in adjoining property A, a building about twenty-five years old. As these windows were quite hidden away—not only as shown on sketch, but by trees and buildings—no one concerned with property B knew of their existence. They seem to have been put there without consent or knowledge, but there is no doubt that two of them have existed for more than twenty years. Present owner of A is unwilling to arrange for alternative rights on own or other side of bedrooms, although owner of B is willing to bear expense. I believe that if a right is blinded or obstructed no right can be established. I would be glad to know if, in your opinion, there has been such blinding or obstruction to a sufficient extent in this case."



A QUESTION OF ANCIENT LIGHTS.

This is a somewhat unusual case—in fact we do not know that any similar one has ever been contested. Apparently A has acquired a right of light to his windows, and that without B having ever been aware of the existence of the windows, and could obtain an injunction to prevent B from building so as to obstruct his light to a greater extent than it was obstructed while the one-storey building existed. This could only be upset if fraud could be proved against A; but it could hardly be fraud upon his part to keep his own counsel. For nineteen years and a day he ran the risk of his windows being discovered and immediately blocked by B, evidently doing so deliberately with the object of securing the permanent advantage which he has now legally obtained, and of which he can hardly be deprived. G. A. T. M.

"Fixed" Inks.

Bradford. — Thick Ink writes: "Most Chinese or Indian inks mixed in the ordinary way have a tendency to run when brushed over. Can this in any way be prevented?"

Yes, by rubbing down the ink with a little ox-gall or soap. "Fixed" inks can be bought in bottles.

Laying out New Roads.

Ashford.—Freeholder writes: "What would be the approximate cost of making a roadway through a clayey meadow the highest point of which is 9ft. 6in. above the lowest? The road will be 40ft. wide. There will be separate pipes for soil and surface water, and the houses will have no basements; so nothing lower than the ground floor will require to be drained. The existing sewer in the lower road is said to be about 6ft. deep. The road would be about 1,200ft. to 1,400ft. long. What would be a fair rough estimate, say, per ft. super. to include everything (pipes, manholes, ventilators, gulleys, &c., curbing and metalling), so that the authorities would take it over? Please also name a good practical book on roadmaking, both as to construction, law and the requirements of local authorities."

Before "Freeholder" can obtain an accurate estimate of the laying-out of the suggested new road in a manner "so that the authorities would take it over," it would, of course, be necessary to know the exact requirements of the local authority with respect to the laying out of "new streets." The requirements vary in nearly every district. It may guide him, however, if we give the approximate cost of forming and laying out a street under the condition he names, and of the following construction (see accompanying figure), which is customary in the vicinity of London, namely: Excavate to give the required "formation" and contour to carriageway and footpaths; lay in 9in. of good, sound hardcore of broken stone or brick, and overlay with 6in. of broken stone (granite), and thoroughly consolidate both the hardcore and macadam-surface with a 10-ton steam roller; provide and fix 12in. by 6in. granite edge curbing, and channels formed of four courses of 6in. by 4in. granite blocks laid on concrete. The footpaths to be paved with 2in. brick-paving laid on 4in. of Portland-cement concrete, with a crossfall of about 1 in 40. This road is assumed to have two 7ft. 6in. footways and a 25ft. carriageway—total width 40ft. The sewers are assumed to be laid at 5ft. and 6ft. deep respectively for the storm-water and sewage-sewer respectively, with all necessary manholes, gulleys, &c.

The cost of constructing such a roadway would be from 36s. to 40s. per foot of length; *i.e.*, for a road 1,200ft. long the cost would be 1,200 at 36s. = £2,160. It should be understood, however, that any such estimates of cost must necessarily vary with local conditions, and the foregoing is the approximate cost of a roadway formed in the manner above specified in the immediate vicinity of London. Application should be made to the local authority of the district in which the road is to be laid out for a copy of their by-laws as to the laying out of "new streets," giving also the requirements before the taking over of the road. The only book we know dealing with both the construction and the law as to the laying-out of new streets, and also with the making-up of the same under the Private Street Works Acts before taking over by the local authority, is "The Construction of Roads and Streets" (price 3s. 6d.) by Mr. William H. Maxwell, Assoc. M.I.C.E., borough engineer, Tunbridge Wells—which deals fully with the construction of streets as above, as to the mode of adoption of "private streets" by local authorities, and other practical details. X

Floor for Assembly Room.

Ayr.—Construction writes: "Which is the most effective and simple method of constructing an assembly-room floor to give it the spring and resiliency necessary for dancing upon? The floor I have in view will be about 60ft. long by 56ft. wide."

Two replies to enquiries respecting the construction of ball-room floors were published respectively on page 189 of our issue for April 10th and page 104 of our issue for March 13th last. From these replies querist will doubtless be able to obtain the information he desires.

Determining Area of Irregular Piece of Ground.

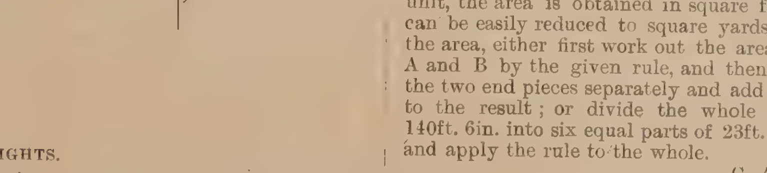
Wrexham.—Cambria writes: "I have been trying to ascertain how to determine the area in superficial yards of an irregular piece of land, and note the article in your issue for April 10th, by Mr. G. A. T. Middleton, but I am not quite clear as to the working of the calculations, it being there in links while I have it in feet. I enclose a sketch of the land."

In order to apply the rule given in the article referred to, the offsets should have been taken at equal distances apart, and this has only been done between A and B. The substitution of feet for links is of course immaterial, as a rule which is correct for one unit must be equally correct for any other unit. If a foot be adopted as the unit, the area is obtained in square feet, which can be easily reduced to square yards. To find the area, either first work out the area between A and B by the given rule, and then calculate the two end pieces separately and add their area to the result; or divide the whole length of 140ft. 6in. into six equal parts of 23ft. 5in. each, and apply the rule to the whole. G. A. T. M.

Air-Space at Rear of Building.

Birtley—B. B. writes: "Several plans of mine have been rejected because there was not a space of 15ft. between an offshot scullery built into the yard and the back wall of the yard itself. If I read the by-law aright, this does not mean the yard wall of the house to be the limit of the distance back, but any adjoining buildings; so that if there were a back street 20ft. wide I could come out to my backyard wall, carry the offshot 20ft. high, and still be within my right, so long as I had 150ft. super. of space in the yard."

Clause 54 of the Model By-laws issued by the Local Government Board states that "every person who shall erect a new domestic building shall provide in the rear of such building an open space exclusively belonging to such building, and of an aggregate extent of not less than 150 sq. ft., and free from any erection thereon above the level of the ground, except a water-closet, earth-closet, or privy, and an ash-pit. He shall cause such open space to extend, laterally, throughout the entire width of such building, and he shall cause the distance across such open space from every part of such building



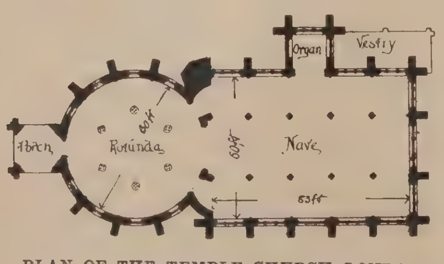
DETERMINING AREA OF IRREGULAR PIECE OF GROUND.

to the boundary of any lands or premises immediately opposite or adjoining the site of such building to be not less in any case than 10ft. If the height of such building be 15ft., he shall cause such distance to be 15ft. at the least. If the height of such building be 25ft., he shall cause such distance to be 20ft. at the least. If the height of such building be 35ft. or exceed 35ft., he shall cause such distance to be 25ft. at the least." Taking this by-law precisely as it stands, the open space must extend throughout the whole width of the building, and at the same time belong exclusively to it, so that it cannot include any adjacent open space such as that afforded by a public road or passage at the rear of the building. From the general statement submitted it would appear that the by-laws operative in your particular district contain a clause closely analogous to the one above quoted. In the case of *Jones* v. *Parry* (which necessitated the determination of the legal construction placed upon a somewhat similar clause) a dwelling-house had been erected which was 25ft. in height at the rear. It was at the same time shown that there was also an open space in the rear of the building, exclusively belonging to the building, of 700 sq. ft., with a distance of 8ft. between the building and the public street, and 52ft. between the building and the boundary of the property on the opposite side of the street. A decision was given to the effect that the public street constituted the "opposite property," and that the local by-law in question required a distance of not less than 20ft. between the building and such "opposite property." Under these circumstances (and in the absence of any definite or specific provision relating to the erection of domestic buildings on sites which abut on two or more streets), the district council may therefore refuse to sanction the arrangement mentioned. T. E. C.

The Temple Church, London.

Kendal.—F. S. writes: "Where can I obtain a description, with illustrations, of the Temple Church, London?"

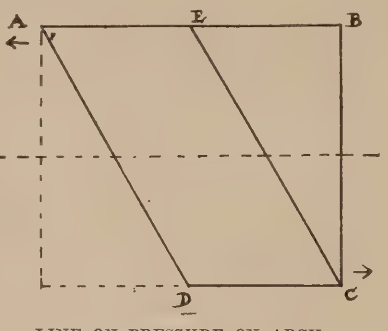
Like most of the churches of the Knights Templars, the original Temple Church, London, was small and circular on plan. It is one of the most interesting examples which we have of the transition from the Norman to the Early English Gothic, with a great deal of rich Norman ornamentation, particularly in the western porch, while internally there are pointed arches and Gothic foliage capitals with pure Norman work above, though necessarily later in date. An inscription preserved in the wall over the west door shows that it was completed and dedicated in 1185 A.D. It runs as follows: "Anno ab incarnatione domini MCLXXXV dedicata hec ecclesia in honore beate Marie A. Dno. eraclio dei grâ sîe resurectionis ecclesie patriarcha IIII idus Februarii q. ea. annatim petêtib de iiunata spenitêtia LX dies indulsit." A choir of three parallel aisles of equal height was added eastwards in a pure and beautiful type of Early English work, with groined vaults and rib-mouldings and with triple lancet windows, and the whole was reconsecrated, in the presence of the king and many of the chief nobility, in 1240 A.D. A careful restoration was carried out about fifty years ago. Notice the absence of agreement between the piers and buttresses of the rotunda. G. A. T. M.



PLAN OF THE TEMPLE CHURCH, LONDON.

Line of Pressure in Arch.

Hamilton.—J. P. writes: "Kindly explain how the 'line of pressure' in a concrete arch on the skew acts. Does it act parallel to the face or at right angles to the abutment; or does it take a mean position between the two? I shall also be glad to have any other information on concrete arches not usually given in text-books."



LINE ON PRESSURE ON ARCH.

The direction, on plan, of the pressure produced by an arch or vault depends on the shape of the area covered, and also, in the case of skew arches, it may depend on the relative proportions of the depth and span. In an ordinary semicircular vault of concrete the horizontal pressure produced by the weight of the crown is uniform, and at right angles to the axis; the result being, in case of weakness, a parallel fracture along the haunches. If a portion of the vault be cut away obliquely as at A D in the diagram, then obviously the pressure of A B C D will be unequal and converge towards C D. But if E B C be also cut away, uniformity of pressure is restored, though not at right angles to the axis, but parallel to the faces of the arch. This obliquity is the cause of the inherent weakness of a skew arch, viz., its tendency to slide in the directions indicated at A and C; and the fractures due to pressure would not be parallel to the axis, neither would they be square with the faces of the arch, but assume a direction somewhere between the two. The depth of a skew arch of fixed span may, however, be increased until the effect of oblique pressure is quite neutralised by the length of the vault; the pressure is then practically square with the axis, only assuming an oblique direction towards the ends, and the lines of fracture would take a direction generally parallel to the axis.

For arches and vaults not subject to unusual strain or vibration concrete is perhaps the most suitable material, especially for intersecting vaulting and skew arches, where the jointing, if in brick or stone, would necessitate an amount of labour hardly appreciated in these days excepting by the workman.

Then, again, a vault of concrete may be readily graduated in thickness to meet statical requirements, while the use of Portland cement will allow of the general tenuity of the shell being maintained, and consequently of a limitation of the weight—advantages that increase with the size of the vault. For very large contracts, when the cement is sometimes delivered fresh from the mill, it should be cooled by spreading it on the dry floor of an enclosed shed before using; this precaution will correct the expansive or "blowing" property of the cement, but if neglected there may be some risk of a vault rising at the crown if the abutment remains firm. As a binding aggregate there is no better material than clean hard broken brick or stone chippings; the gauging and mixing should have constant supervision, and the concrete should be laid on the centering in a uniform manner, in courses the full thickness of the shell, and not more than 2ft. or 3ft. in height; thus the liability of the loose material to slip over the work below is lessened, and the setting is uniform. By completing both sides of a vault simultaneously, or the whole ring of a dome, as the case may be, the weight on the centering is equalised. The haunches of a vault are generally solid concrete up to about one-third of the height, and this portion should be incorporated with the enclosing walls by forming projections or toothings on the walls not less than 6in. apart. In addition to these toothings, stone landings may with advantage be built across the angles of square compartments, to distribute the weight of a groin or a pendentive; and for some height above the springing the curve, in this case, is best formed with the walling, in horizontal courses. The springing of a vault or arch of concrete should not, if it can be avoided, be let into a chase; the wall should either be reduced in thickness at this level, or corbelled out, so that the walls and piers may be completed independently of the concrete.

For a concrete floor over a vault enclosed by walls the upper part of the haunches may be filled in with a lighter material such as dry brick rubbish, but it is better to convert this into a light kind of concrete, say, eight or ten of broken brick to one of lime, thrown in but not rammed. When a vault is large it is still better to build transverse walls 4ft. or 5ft. apart, to support a thin concrete floor cast *in situ*, leaving temporary openings through which the centering can be got out. Empty spaces should be ventilated. In very hot weather the concreting should be done under tarpaulin covers. Needless to say, the striking of the centering should not be hurried. J. A. M.

French Architectural Journals.

Newcastle-on-Tyne.—B. P. writes: "Can you tell me what are the architectural papers in France that are equivalent to ours? I want some illustrations of modern Parisian fronts, and also of drawings to which the Prix de Rome and other prizes have been awarded in recent years."

This enquiry respecting architectural papers in France has been replied to several times in these columns. So far as we have been able to ascertain, such papers are very few indeed, thus being very different to the United States and Germany; but we have recommended "La Construction Moderne," a paper published weekly and to be obtained from Messrs. Grevel & Co., 33, King Street, Covent Garden, W.C., price £1 15s. per annum. Subscriptions start only from April 1st and October 1st.

Phœbe Hearst Competition, California.

Newcastle-on-Tyne. — B. P. writes: "I should be glad to know where I could obtain illustrations of the prize scheme for the Phœbe Hearst architectural competition for the University of California, other than the odd one or two published in the papers here."

An article on this competition, written with the assistance of Mr. John Belcher (one of the assessors), was published in the "Architectural Review" for March, 1900, together with full-page illustrations of the premiated designs; but if querist desire complete illustrations and particulars, he had better obtain the large pamphlet which was issued by the trustees, whose address was Room 3, 217, Sansome Street, San Francisco, California. Considerable space was also devoted to the matter in the "California Architect and Building News" (408, California Street, San Francisco), the first premiated design, by M. Benard, of Paris, being fully described and illustrated in the issue for September, 1899. The subscription to this journal is 3 dollars a year.

The Westminster Abbey Fiasco.—Mr. J. T. Micklethwaite, surveyor to Westminster Abbey, writes to "The Times" correcting the exaggerated report about the recent fall of a small marble shaft in the Abbey. This fell from one of the windows through the giving way of an iron pin which had held it in its place for six centuries and a half. "The failure is a curious one from a mechanical point of view, but it does not in any way affect the stability of the building. Indeed, except from the surface decay of the stone, which is a very serious matter, there is no part of the church in a condition to cause anxiety."

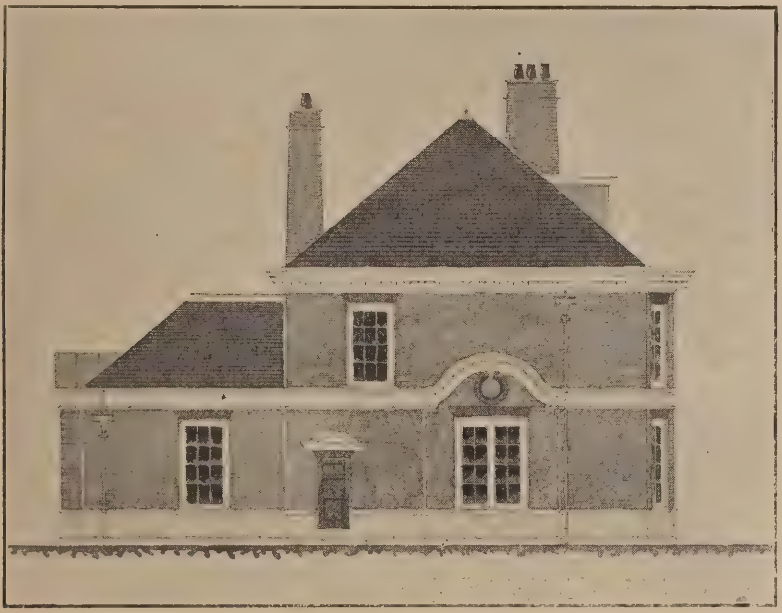
Bricks and Mortar.

APHORISM FOR THE WEEK.

Art is Nature's rival.—APULEIUS.

Our Plates. THE materials to be used for the house in Surrey designed by Mr. Arthur Edmund Street, of 37, York Street, York Place, W., are Bracknell red facing bricks with Horsham stone dressing and Westmorland green slates for the roof.—The development of the Art movement in Whitechapel has been steady, encouraging, and sure. Separate, suitable and permanent accommodation has now been obtained in the new gallery, opened on March 12th with a fine and representative exhibition of English art. As an evidence of its success, we may state that during its first five weeks 190,000 persons visited it. The new building is next door to the Public Library in the High Street, and occupies a peculiarly difficult and awkward site. Apart from its restricted area, which makes it necessary to have a second gallery on the first floor in order to secure adequate accommodation, the site is not rectangular, and this has considerably increased the architect's difficulties. The party-wall troubles have also been a source of worry, and the question of entrances and exits, in order to secure the necessary circulation of visitors, has occasioned considerable trouble in planning. The lower gallery consists of a nave and two aisles. The two latter, being top-lighted, supply light to the nave. The necessity for an upper gallery prevented a direct light being given. The total length of this gallery is 100ft., and it has a total width, including the aisles, of 48ft. At the rear of the building is the approach staircase to the first floor, and just beyond this, to the left, is a small annexé, top-lighted, which can be used, if required, for special exhibits. The main staircase has been placed at this end of the gallery to enable visitors who have viewed the exhibits there to ascend to the upper gallery without retracing their steps. In the same way visitors who have passed though both galleries will leave by the special exit stairs in the front of the building, the meeting of two streams of people entering and leaving, being thus avoided. The upper gallery, on the first floor, is 120ft. long by 26ft. wide, and is top-lighted. On the same floor is the committee-room, lighted by small windows on the front. On the second floor is situated the caretaker's rooms and store-rooms. In the basement there is a heating chamber with separate cellars for coal and coke, with shoots from the pavement. The main front is of buff terra-cotta by Gibbs & Canning, of Tamworth. A large mosaic panel 25ft. long and 13ft. high will form the principal decorative feature of the elevation. It will cover the recess between the two turrets, and have a protection from the weather in the pent-roof above. Two or three designs for the panel have been prepared; but that by Mr. Walter Crane, illustrating "The Sphere and Message of Art," is the one that will be carried out. We give a reproduction of Mr. Crane's sketch design. The gallery will accommodate about 450 pictures on the two floors. The building is also adapted for concerts and meetings when not in use for exhibition purposes, and the architect, Mr. C. Harrison Townsend, F.R.I.B.A., has still under consideration the question of a further exit at the rear of the premises. The contractors for the work were Messrs. J. Outhwaite & Son.

Disappearing London. IT seems that a number of picturesque old buildings in Royal Mint Street will disappear shortly in connection with the Tower Bridge improvement scheme. They stand right in the path of the approach, from the Middlesex side, to the bridge, face the north-east angle of the Tower, and overlook the open space known as Little Tower Hill. The houses form, with those beyond, the base of a triangle of ancient buildings. Between the two lies a little street, one of the many "King Streets" in the Metropolis. But this "Tower" King Street leads from nowhere to nowhere. At the corner of King Street, at the northern entrance, is a specimen of eighteenth century architecture, the Crooked Billet Tavern, having a high pitched red-tiled roof, with dormer windows. Generally speaking, the house is in its original condition. Its front, overlooking Little Tower Hill, has been rebuilt, and is not interesting, but the King Street side keeps its original entrance, and the usual formal pilasters with a frieze of the Greek honeysuckle in plaster.



A SURREY HOUSE: WEST ELEVATION. A. E. STREET, M.A., F.R.I.B.A., ARCHITECT.

Chichester Cathedral. THE north-west tower of Chichester Cathedral, which has been rebuilt at a cost of over £8,000, was dedicated recently by the Archbishop of Canterbury. No authentic records are in existence as to the exact circumstances in which the old tower fell, but the disaster is supposed to have happened about the year 1634, the cause most probably being the defective nature of the foundations. Not until the episcopate of the late Dr. Durnford were any active steps taken towards the rebuilding of the tower. When a fund was started for the general restoration of the cathedral the executive committee found that, owing to the insecurity of the west bay of the nave vault, the rebuilding of the north-west tower was the work which most demanded attention. The late Mr. J. L. Pearson prepared a design for the rebuilding of the tower, which, subject to certain modifications, was ultimately adopted. The south side of the tower, forming part of the nave of the cathedral, was intact, although the arches of the triforium and clerestory stages were walled up. All that remained was to carry the same design round the three remaining sides, but there was a good deal of controversy as to the character of the exterior of the building before a satisfactory agreement was arrived at. Messrs. Luscombe & Son, of Exeter, were given the contract for the work, which was carried out in sections, the money for each section being first obtained in subscriptions before the next stage was proceeded with. Mr. Frank Pearson succeeded to the duties of architect on the death of his father. The new tower, which resembles in its general character the south-west tower, is about 34ft. sq. over all, and from floor to ceiling, a height of nearly 100ft., is open to the cathedral. The work has occupied about 2½ years.

St. Sidwell's, Exeter. DEDICATED to St. Sativola, a British saint of whom Professor Freeman seems to be dubious, the original church, St. Sidwell's, Exeter, seems to have disappeared, the present having been built in 1813. At some period or other the red Heavitree stone was covered with plaster. When this was removed it was found that the tower had been in large part transformed from its fifteenth century character, and that a good deal of brick work had been introduced. Enlarged and improved in 1871, the church was afterwards cased with grey stone, in striking contrast with the red stone of the tower. A few years ago a steeple which had been stuck upon the tower was removed, and now the tower is being restored to its early character. In the lower part is some of the fifteenth century work, and the remainder of the structure will be renewed in the style of the Perpendicular period. This restoration will cost about £3,000.

Evolution of Japanese Art. MR. WALTER BEHRENS recently read a paper concerning evolution in certain forms of Japanese art before the members of the Japan Society. Mr. Behrens did not deal with Japanese art forms in general, but confined himself almost altogether to a brief discussion on various forms of netsuké and their uses. He remarked that his subject was naturally not touched upon in any Japanese writings, as the idea of evolution was comparatively modern, and he believed that the Japanese had only arrived at it through our aid. The matters he had to speak of had not been touched on in any records, and the only documents he had were actual examples he had seen, so that he feared his researches must always remain empirical. He was certain that evolution was to be found in the art of Japan. This art was so closely connected in its origin with the art of Corea, of China, and other countries, that it was difficult to come to decisive conclusions. All who had collections of Japanese art work would note that such dates as were inscribed or added to signatures gave no trustworthy information as to the actual period of production. He feared that Japanese experts, like Roman authors, must laugh in their sleeves when they met; at any rate, their theories were remarkable for their divergence. It might be suggested that in Japanese art, shackled by convention, the germ of development had been sterilised, but signs of alteration and life were visible. Once the use of the brush had been acquired any change in the resultant use was not so much evolution as a change of taste, and taste was nearly always an accident, not a growth. By this he implied that taste, like fashion, generally received its impulse from one individual, and its effects were therefore arbitrary. Evolution was change that was unconscious and practically imperceptible. His studies had all been directed to the investigation of objects in personal use among the Japanese, particularly of the netsuké, or the elaborate ornaments by which objects were suspended from the girdle. Mr. Behrens said it seemed to him likely that it was from the seal form that netsuké in their various presentments rose. It was highly probable that before the netsuké *qua* netsuké came into being it was a seal. Seals both in China and Japan dated from long before the Christian era. Most of the early netsuké were figures of men or animals carved in ivory. The seal was a very important adjunct with the Japanese, and was a much greater indication of identity than a signature. Hence father and son had different seals, and copying a seal was a much worse offence than forging a signature. In lacquer and metal work the evidence of evolution was more ready to hand than in the case of netsuké, but nevertheless there was a wide field for research in this direction also.

OUR NEW ACCIDENT INSURANCE SCHEMES.

Important to all Subscribers of the "Builders' Journal."

The necessity of signing an Insurance Coupon week by week had such great disadvantages, that we have initiated the following Schemes for the benefit of Subscribers to the "Builders' Journal." We have entered into an arrangement with the Ocean Accident and Guarantee Corporation, whereby we are enabled to give three alternative Schemes of Accident Insurance which are unique, and have in addition the great merit of simplicity.

The only condition attached to the Schemes is that the benefits shall apply solely to those who become subscribers to the "Builders Journal" for ONE YEAR.

THE SUBSCRIPTION MAY BE MADE DIRECT TO THIS OFFICE, OR THROUGH ANY NEWSAGENT.

The great benefit of the Scheme is that an INSURANCE TICKET is issued with each Annual Subscription, and readers, therefore, dispense with the Signing of Weekly Coupons.

Our Three Unique Schemes.

No. 1.
FREE INSURANCE.
£500.

The sum of five hundred pounds will be paid to the legal personal representative of the bonâ fide owner of the Insurance Ticket if such owner shall be killed by an accident within the United Kingdom to any passenger train, public omnibus, tramcar, or four-wheeled or hansom cab (driven by a licensed driver plying for public hire), and who, at the time of death, is an annual subscriber to the BUILDERS' JOURNAL. No payment other than the amount of the annual subscription is necessary, and the Insurance Ticket will be forwarded with the receipt. When ordered and paid for through a Newsagent, the conditions stated on opposite page will apply.

* * *

No. 2.
Annual Premium of 1/-
£500
at DEATH and
£250
for Permanent Total Disablement,
£2 10s.
per week for Temporary Total Disablement.

By the payment of an Annual Premium of **1s.,** in addition to the Annual Subscription to the BUILDERS' JOURNAL, readers will be insured in the event of Death by Accident as in Scheme No. 1, but will further be insured to the extent of **£250 IN THE EVENT OF PERMANENT TOTAL DISABLEMENT,** which may result from an accident from any of the aforesaid causes, and also **THE PAYMENT OF £2 10s. PER WEEK** for a period not exceeding 10 weeks, in the event of Temporary Total Disablement. When ordered and paid for through a Newsagent the conditions stated on opposite page will apply.

Any further particulars regarding the Scheme may be had by applying to the Manager—

BUILDERS' JOURNAL, Effingham House, Arundel St., Strand, W.C.

OUR NEW ACCIDENT INSURANCE SCHEMES.

The following Scheme is most important, as our Subscribers are not only insured against EVERY POSSIBLE ACCIDENT that might happen to them, but also against

INFECTIOUS and OTHER DISEASES, as specified below.

It also carries an ANNUITY and a LARGE WEEKLY SUM PAYABLE FOR 52 WEEKS.

No. 3.

SPECIAL POLICY

Covering all Risks.

Under this Scheme, by payment of an ANNUAL PREMIUM (which includes one year's subscription to the "Builders' Journal")

A. £3.

Applicable to **Architects, Surveyors, Civil Engineers, Travellers, Salesmen, &c.**

B. £3 10s.

Applicable to **Builders, Builders' Clerks, Overseers, Engineers, House Decorators, Packers, &c., and such hazardous risks.**

This Excellent Insurance Scheme insures

In Case of Accident

CAUSING	Railway or Tram-car Accidents.	Other Accidents.
Death	£1,000	£500
Loss of Hands or Feet or Eyes, or of one Hand or Foot and one Eye ...	£1,000	£500
Loss of one Hand, Foot or Eye	£500	£250
Temporary Total Disablement	£6 Weekly.	£3 Weekly
Temporary Partial Disablement	£1 10s. Weekly	15s. Weekly
Permanent Total Disablement arising from injuries other than those specified above	£30 Annuity	£15 Annuity
Weekly Compensation payable up to **52** Weeks.		

In Case of Illness.

£3 a week during Total Disablement caused by Diabetes, Asiatic Cholera, Typhoid or Typhus Fever, Scarlet Fever, Small Pox, Tetanus, Diphtheria, Pneumonia, Pleurisy, Erysipelas, Measles, Carbuncle. Compensation payable up to **26** weeks.

£250

In case of Total and Irremediable Blindness or Permanent General Paralysis, not caused by accident.

Each Scheme is applicable only to Annual Subscribers. The Annual Subscription by post direct from the Office is 10*s.* 6*d.*, which includes scheme 1. When Schemes Nos. 2 or 3 are being subscribed to, the additional premiums must be remitted with the subscription for the Journal.

Where a person may prefer to have his copy week by week through the medium of a Newsagent, it will only be necessary for the Newsagent to forward to the office a declaration that the person in question has paid to him a subscription for one year and for Schemes 2 and 3 to remit the premium. The ticket or policy will be forwarded through the Newsagent who makes the declaration.

* * *

Any further particulars regarding the Scheme may be had by applying to the Manager—

BUILDERS' JOURNAL, Effingham House, Arundel St., Strand, W.C.

Law Cases.

Mrs. Langtry's New Theatre: The Contractors Fined.—Messrs. John Allen & Son, Ltd., contractors, of Palmerston Works, Kilburn, were summoned at Westminster last week for obstructing the free passage of the highway at Tothill Street, Westminster, by allowing a quantity of rubbish and building material to remain on it. Sergeant Haines, 42 A, said that the carriageway was largely obstructed during the reconstruction of the Imperial Theatre. There were iron asphalt boilers, heaps of rubbish and coke-breeze, mortar, &c., for a space of 30yd. by 4yd. Inspector Cussins said that for weeks the roadway had been quite blocked. Counsel for the defence took several objections to the summons, and urged that there was no more obstruction than was consistent with extensive building operations. The Police Act exempted builders' materials. The magistrate said it was evident the police had recognised the difficulty under the Police Act, and had, therefore, gone under another statute. He had to look after the public and not individuals. He fined the defendants 40s. and costs on each of the three summonses.

A Sequel to the Funeral Procession.—Several summonses were heard at Westminster last week against the occupiers of premises in the Victoria district for infringements of the London Building Act by erecting structures without the consent of the London County Council. Mr. Chilvers, who supported the summonses, said that they were taken out in consequence of structures put up on the occasion of the funeral of her late Majesty the Queen. Some of the erections were in shop windows, and one on the roof of a house, and he submitted that these were structures for which plans should have been approved. The stands were put up at the last moment, and sometimes in a very loose manner; and unless they were submitted to the Council the district surveyor had no knowledge where they were. Fines varying from 5s. to £2 2s. were imposed.

Apportioned Cost of Paving New Streets: Interesting Decision.—The case of the *Property Exchange (No. 1)* v. *the Wandsworth Board of Works* was heard in the King's Bench Division of the High Court of Justice on Thursday last. This was an appeal by case stated from the order of a metropolitan police magistrate ordering the appellants to pay to the respondents the sum of £69 11s. 3d., the amount of the expenses apportioned to them of paving an alleged new street called Totterdown (on the north side thereof), Tooting. The Court dismissed the appeal. The Lord Chief Justice said that there was a good deal to be said for the view that, where a road was so altered that practically a new street was made out of what was an old highway, it might not be unreasonable to treat it as a new street as to the whole. But the decisions were too strong for that view to be taken. It was not disputed that where premises fronted on a new street, then, though the paving was only as to part of the street, the frontagers on both sides of the street were chargeable. That was decided in *Vestry of Mile End* v. *Guardians of Whitechapel*. But in the case now heard the respondents' counsel contended that where there was a highway, and a new part is added to it by the frontagers of one side, then that part was the new street and not the whole roadway. His lordship was of opinion that he was right, having regard to the authorities. In *Richards* v. *Kessick*, which was decided under the Public Health Act, the Court of Queen's Bench held that for the purpose of the Public Health Act a strip of land added by the adjoining owners to a highway formed with the houses a "street." Mr. Richards, counsel for the appellants, did not deny that that case in principle bore upon the matter, but he said that it was under a different Act from that now in question. The question was whether there was any real difference in principle between the two Acts. In *White* v. *Fulham Vestry* the facts were much the same as in the present case, with one difference—namely, that an older portion of the roadway had become a new street since 1855, and the frontagers had paid the expense of paving it. Then a new bit was added, and it was held that the added portion was a new street and that the expenses of paving it ought to be apportioned among the frontagers on that side only. Mr. Richards had pressed them to say that the sole ground of that decision was that the frontagers of the original part had already paid. That was true, but when one looked at these judgments, both in that case and in *Richards* v. *Kessick*, one saw that the Court held that the new strip was the street or new street. It could not, in his Lordship's opinion, matter whether the original part was a new street made up under the Act of 1855 or an old highway. He thought that the learned magistrate was right in following the authorities, and that the added piece was a new street. Mr. Justice Lawrance concurred.

Masters and Men.

Building Dispute at Newmarket.—The carpenters and bricklayers employed in erecting the new Great Eastern Railway Station at Newmarket struck work last week, the contractor having employed other men to lath and slate the roofs, which the strikers consider to be their work.

Building Dispute in Berlin.—The "Vorwärts," the German Socialist organ, states that the Union of Master Builders of Berlin has determined to lock out until the end of the week all workmen who leave off work on May 1st. As May 1st falls on a Wednesday this action would mean the loss of four days' wages to the men.

The Bricklayers' Labourers at Barrow have struck because the master builders decline to advance wages from 6½d. to 7d. an hour. The latter is the rate paid to labourers working at Vickerstown, but this is because they have further to go. The building trade is very brisk in Barrow, and the strike will cause much inconvenience.

The Aberdeen Operative Plasterers, who have been on strike nearly seven weeks, have accepted a compromise offered by the masters as a basis of settlement of the dispute. The employers proposed to reduce wages from 8½d. to 7½d. an hour, but the men rejected these terms and came out on strike. As the result of the conference, the masters agreed that the wages be 8d. per hour, and the men have now accepted that rate.

The Belfast Carpenters' and Joiners' Strike, which has continued for fifty-one weeks, has now been settled at a conference of the disputants. The Very Rev. John M'Mullan, C.P., rector, Ardoyne, acted as arbitrator. The men return to work under 1899 Rules, except that Rule 1 now reads, "54 hours per week, 12 o'clock stop on Saturday, 8½d. per hour," and Rule 4 "Outside the Boundary lines men to be paid extra for a mile or a part of a mile, 2s. per week; above 1 and not exceeding 2 miles, 3s. per week; any distance between 2 miles, 4s. per week." Where these extras are paid, men are to work the usual hours as if employed in Belfast. No reduction is to be made in wages for two years, and an advance to be given in May 1902 if trade warrants it.

The Effect of "Combines" on the Workers.—Speaking recently at Motherwell, at the annual meeting of the employees of Parkneuk Bridge Works, ex-Bailie Findlay, the managing director of the company, said he believed in individual effort and enterprise, and did not wish to see them dominated by those huge combines which often crushed out the independent and smaller trader or manufacturer in order to be able to dictate their own prices. These combines were so imbued in the commercial spirit that the sole problem seemed to be how to swell the profits, and the workmen were mere parts of the machine. The spirit of American push-and-drive, and the "firing out" of unsatisfactory workmen and men who had passed the age of forty, especially under big combines, might result in large bodies of employees being driven hither and thither like flocks of sheep, till, like the worm when trod on, they turned, and great industrial disorder and distress would ensue. It was true that higher wages were paid to the American artisan than is the rule here, but his hours were longer, and he went at his work with a much keener intelligence and energy, his usual pace being what we associate with piece-work. But a skilful and energetic man here, working on piece-work, was as well off as in America or the continent of Europe. There was one striking point in America, and that was that the average workman there was somehow more self-respecting than we find him here, and an unsteady workman was practically unknown in that country.

New Patents.

The following specifications were published on Saturday last, and are open to opposition until June 3rd. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—5,659, Wright, setting for cements. 5,953, Eccles, weatherboard for doors. 6,318, Loehle, roofs. 6,338, Von Hedemann & Von Hedemann, slabs or panels of plaster of Paris. 6,819, Baumer, instruments for surveying and plotting without calculation. 6,920, Williams, cranes and hoisting apparatus. 8,002, Koerfer, glass bricks or blocks. 8,224, Goldie, structures for the bacterial treatment of sewage. 8,638, Löblich, distributing valves for baths. 8,818, Lewis, slate mantelpieces. 8,822, Boys, tool-grinding appliances. 8,973, Genese, acetylene lamps. 8,995, Wise (firm *Xav. Reichlin*), apparatus for closing doors. 9,601, Seefels & Soldan, constructing fire-resisting and ventilating floors, ceilings, &c. 9,654, Hamblet & Parkes, dies for making socketted conduits. 9,673, Braun & Morrison, window blinds. 9,779, Feeny (*Spaulding*), sash locks. 9,862, Smith, siphons for cisterns. 10,266, Shanks & Burnside, water-supply taps and valves. 14,365, Borgars, brick. 20,257, Douglas, apparatus for cooling air. 21,638, Kaeferle, unions for pipe joints. 23,651, Grastorf, construction of ceilings, roofings, &c.

1901.—478, Kautny & Lotz, acetylene-gas generators. 2,226, Huxley & Henry Simon, Ltd., machines for measuring powdered materials. 2,268, Lake (*Fried. Krupp Grusonwerk*), presses for the manufacture of lead and other pipes. 2,481, Riedel & Schiegner, dies for brick machines. 2,921, Garvens, pumps. 3,040, Newton (*Savery*), machines for winding lengths of paper in rolls. 3,301, Hargrove, door springs. 3,552, Tomkins, guiding lifts and elevators.

Engineering Notes.

Bill for widening London Bridge.—On Thursday last in the House of Commons this Bill was ordered to be read a third time.

Electric Lighting Extension in Leeds.—It is proposed to borrow half a million of money for electric lighting purposes in Leeds, and a Government enquiry on the subject was held last week.

Electricity on the Underground.—The schemes for adopting electricity as the motive power on the Metropolitan and Metropolitan District railways are being developed with as much rapidity as possible, but as yet no particular system has been definitely settled.

A Newcastle Railway Scheme.—The North-Eastern Railway Co. is now inviting tenders for a scheme for continuing the old Blyth and Tyne line from New Bridge Street, Newcastle, to near the Manors, and of improving and enlarging the station accommodation at that part of the town.

Northampton Tramways.—The Northampton Corporation have decided to take steps to acquire, by compulsory powers, the Northampton Streets Tramways. The committee acting on behalf of the Corporation offered £37,500, and the tramways company asked £45,000. The total cost of the undertaking, which has been in existence twenty years, was £56,000.

Institution of Mechanical Engineers: President's Address.—Mr. William H. Maw delivered his presidential address to this Institution on Friday evening last. We have received a copy of it through the courtesy of the secretary, but are obliged to hold over our report, with some comment, till our next issue, owing to the great pressure imposed on our space by the Building Trades' Exhibition.

GLASGOW EXHIBITION.

PRESENT CONDITION OF THE BUILDINGS.

A WALK through the Kelvingrove enclosure at Glasgow will convince the visitor that there is not a minute tosp are if the public are to be enabled to survey the grounds and Exhibition buildings with satisfaction by the beginning of May. But while that is so, says the "Glasgow Herald," one ought not to take too pessimistic a view of the situation, as the work which yet remains to be accomplished is of such a character that rapid progress towards the completion of the whole undertaking can be reasonably expected.

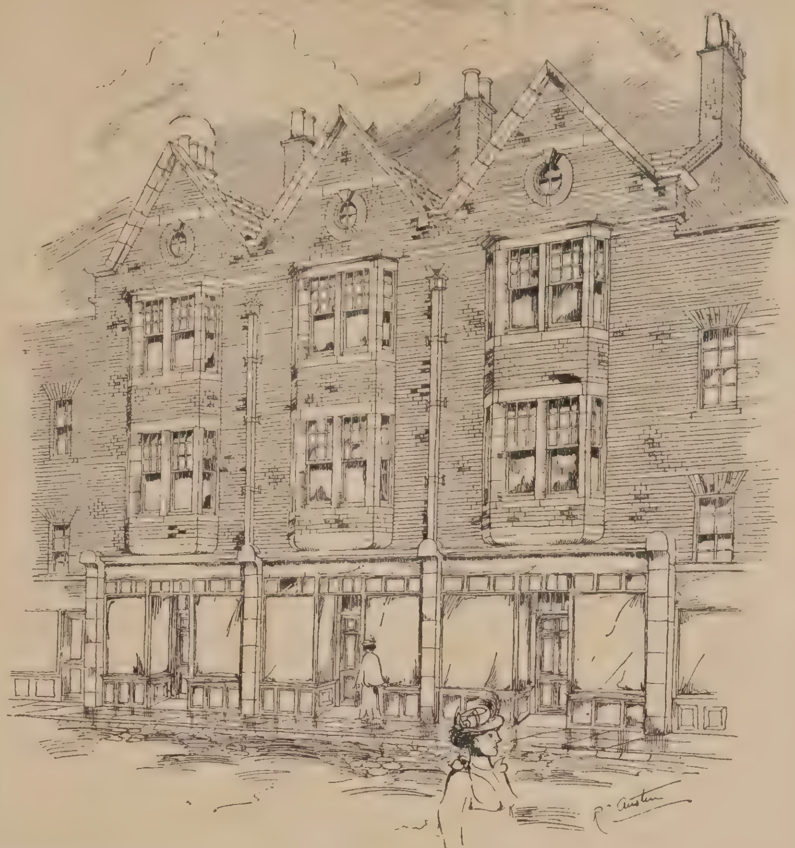
Starting from the east end of the park, the visitor's attention is first arrested by the Russian buildings. Of the four pavilions, the one devoted to agricultural exhibits is nearest completion. Externally little remains to be done. The decorations, which are in harmony with the quaint and picturesque design, and have a highly artistic effect, are almost completed; and so far as one can judge from the examples of the Russian painters' skill on the surrounding buildings, a brilliant contrast in rich colouring is being aimed at. Large cases containing exhibits are stocked in the interior of the agricultural hall, and this section should be in an almost finished state in a fortnight.

The mineral and forestry pavilions are not so far advanced, and upon the large octagonal kiosque intended for the reception of distinguished visitors joiners are still employed. The Irish squireen's house, with its rough-cast plaster walls and thatched roof, stands in striking contrast to the ornate Russian display in the vicinity. On either side of the unbarked timber porch which gives access to the interior tall shrubs and hedgerows have been planted, and they add a delightfully realistic touch to the surroundings.

The Canadian Pavilion was among the earliest buildings to be finished, and the various sections of exhibits are almost ready for inspection. Passing into the Concert Hall the visitor notes that here at least there is room for gratification. The interior of the spacious rotunda is ready for the reception of over 4,000 people, the decorations are completed, and the organ-tuners are at work. The walls of the grand entrance to the hall are being adorned with a coloured tile design, and the reception-rooms for the royal visitors are in an advanced state. Emblematic figures are now in position on the balconies of the main facade of the Industrial Hall, the centre of the peristyle, and the top of the dome. From an artistic point of view, however, they cannot be pronounced a success. Owing to the weight of the outspreading wings the draperies have been utilised as a counterpoise. Cement pavement is being laid in front of the peristyle, and the neighbouring terraces have been put in order.

The new and the old bridge over the Kelvin is now merged into one, and the improvement thus effected in the approach to the main facade cannot fail to be noticed. The avenue leading from the Dumbarton Road Bridge along the slopes of Gilmore Hill is studied with small buildings in a more or less advanced state of construction. The principal restaurants are in the hands of the decorators; and there need be no fear of unpreparedness in this important department. On the leading thoroughfares of the park large supplies of road metal and gravel have been deposited, and whenever circumstances will permit the paths which have been cut up with the heavy traffic will be converted into fine promenades. With a spell of good spring weather the grounds should in a short time assume an aspect that will blend harmoniously with the picturesque buildings of the Exhibition.

New Prize for Painters' Apprentices.—At a meeting of the executive officers of the Associations of Master Painters in England, Ireland, and Scotland, held in the Painters' and Stainers' Hall, London, it was resolved to establish an international travelling studentship, eligible to boys in the last year of their apprenticeship, and to be of the annual value of £50. The competition is to be for general knowledge of the trade, for excellence of executive workmanship in design and ornament, for a knowledge of historic ornament and architectural forms, and a definite scheme of design with working detail.

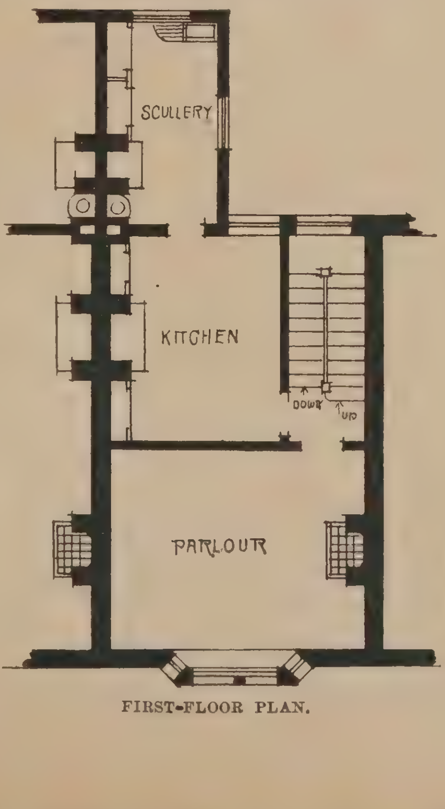


BUSINESS PREMISES IN COMMERCIAL ROAD, E. RUPERT C. AUSTIN, ARCHITECT.

MASTER BUILDERS' NATIONAL FEDERATION.

COMBINED ACTION TO DEAL WITH DISPUTES.

A QUARTERLY meeting of the Executive of the Midland centre of the National Federation of Building Trades' Employers was held on April 19th at the Birmingham offices. The President (Mr. A. Chambers, Leicester) occupied the chair. A long discussion took place in connection with notices given to or received from workmen in various branches of the trade at Burton-on-Trent, Coventry, Nuneaton, Newark, Dudley, Kidderminster, Sutton Coldfield, and other places, and it was pointed out that under the conditions generally observed in the trade these notices now expired at a period of the year when work, as a rule, was most plentiful, and consequently the employers, in order to carry out their contracts, were frequently compelled to make concessions that were unjust to themselves and extracted on unreasonable grounds.



FIRST-FLOOR PLAN.

The President remarked that, as a body, master builders had no desire to act arbitrarily as against their workmen, but from experience they were aware that many of the conditions the workmen's trade unions tried to enforce were detrimental to the best interests of the trade. Mr. J. Wright (Nottingham) said that one of the bugbears of the trade was what was known as the lines of demarcation laid down by the trade unionists. Master builders were for the most part practical men, and were fully competent to carry on their businesses, but in many cases they were not permitted to do so with anything like reasonable freedom. The question was one of great importance to the welfare of the building trade throughout the country, and it behoved the National Federation of Employers to take steps to prevent unjust and meddlesome interference with the masters' common rights. Several speakers took a similar view, and a resolution was passed affirming the necessity for more combined action throughout the kingdom in dealing with disputes in the trade which too frequently lead to strikes and lock-outs. Another point discussed was the desirability for a uniform contract form containing clauses applicable all over the country in relation to such matters as strikes, lock-outs, arbitration, and weather.

R.I.B.A.: Mr. Bond's Paper.—We regret we are obliged to hold over till next week our report of the paper by Mr. Francis Bond, M.A., on "The Classifications of Romanesque and Gothic Architecture," read before the Royal Institute of British Architects on Monday evening last.

Discovery of Ancient Ruins at Gosforth.—It was a tradition at Gosforth that there had been a chapel at what is known as Chapel Brow, a place about half way between Gosforth Hall and Wind Hall. The Archæological Society of Cumberland and Westmorland was induced to take the question up, and put the matter into the hands of their secretary (Mr. W. G. Collingwood, of Coniston). A few hands were set to work cutting trenches and excavating, which soon put the matter beyond doubt that a building of some sort had been on or near the site.

Keystones.

A Statue of the Emperor William I. of Germany has been erected on the Lange Brücke, Potsdam.

A New Roman Catholic Church at Enfield (accommodating 350 people) has been opened.

A new Congregational Church at Waring Green, Brighouse, is being erected to accommodate about 500 persons. The new chapel will cost £2,600, Messrs. Sharp and Waller are the architects.

A New Church House for Folkestone is being erected as a memorial to the late Canon Woodward. The site of the building is on the Bayle, near the parish church, and close to the sea.

The Bishop Otter Memorial College, Chichester, has been enlarged by the addition of a new wing, at a cost of nearly £4,000. The college now affords accommodation for eighty students.

The Archway in Ireland's Yard, Queen Victoria Street, which was unearthed last year, and which antiquaries decided was a portion of the Dominican Priory founded by Henry de Burgh in 1221, has been erected at Selsdon Park, Croydon, in the grounds of Mr. Wickham Noakes.

A State Inebriates' Home.—At a recent meeting of the Kent County Temperance Congress, at Dover, Mr. Joseph Malins said he had every reason to know that the Government proposed to erect a State Inebriates' Home. It was intimated that this institution would be built in East Kent.

At St. Thomas's Church, Bristol, the organ has been re-opened after the addition of a choir organ. The pitch has also been raised to concert pitch, pneumatic action arranged throughout, and the instrument is now blown by hydraulic power. The organ was built by Mr. George Johnson.

Fixing Electric Bells in Houses.—In the paper on this subject by Mr. H. E. Neale published on page 190 of our issue for April 10th, under the cross-heading "Electrical Units," the formula $R = \frac{C}{E}$ is in one case printed erroneously for $R = \frac{E}{C}$.

The Queen Victoria Memorial in Liverpool will have a very fine site between South Castle Street and Castle Street in the centre of the city. The spot was occupied up to a few years ago by St. George's Church, which was built with the stones of Derby Castle, which stood ere that on the same site.

In the Parish Church of Dormington Wood, Salop, the east window has recently been filled with stained glass. The window, which is a large one, has for its subject "The Cruxifixion," which is placed under canopies. In the base are figures of Saints Matthew, Aidan and Chad, while the inscription is to the memory of the late vicar. The window is the work of Mr. T. W. Camm, of The Studio, Smethwick.

A Parish Chapel at Wadhurst Hall, the residence of Mr. Julius C. Drew, was dedicated recently. The enlargement and decoration of the chapel have occupied a period of more than twelve months. The organ was built by the Positive Organ Company, and the building is lighted by the electric light. The work has been carried out by Mr. C. Startin, of Ticehurst, under the superintendence of Messrs. H. and E. Cronk, of Tunbridge Wells.

A Novel Victorian Memorial.—In commemoration of the sixtieth year of Queen Victoria's reign a large carved oak chest, or "press," has recently been presented to the parish church of Frenchay, which is practically a suburb of Bristol: The press is intended for the safe keeping of the different altar frontals, the colours of which indicate the varying seasons of the Church year, and is 7ft. 6in. in length by 4ft. in height. It has carved panels filled in with foliage and designs. An interesting feature in connection with the memorial is that it has been executed by the local Hambrook carving class, under the superintendence of two ladies. Formerly every good-sized church had its vestment press, alms-chest, and other receptacles, and the rude, quaint carving which characterises some of the old examples which have been preserved shows that they were often the product of local handicraft.

A New Art Gallery in Prague is to be erected for painting, sculpture, and architecture for the benefit of both races in Bohemia.

Messrs. E. H. Shorland & Brother, of Manchester, have just supplied their patent Manchester grates and ventilators to the Baptist Chapel, Leighton Buzzard.

A Baptist Chapel at Horsell is being erected for the Anthony's Mission Chapel congregation, midway between Woking and Ottershaw. It is to be in red and white brick. A class-room, a kitchen and a lavatory are attached to the main structure. The site is 90ft. deep, with 36ft. frontage, and the building is placed in a way that will admit of its being easily enlarged to double its present capacity, when the growth of the neighbourhood demands it. Mr. F. J. Bridger is the architect.

A Baptist "Church House" is to be erected in the new main thoroughfare between Holborn and the Strand. A part of the site was formerly occupied by the Kingsgate Baptist Chapel, which has just been demolished, and the remainder has been granted by the London County Council as compensation. The new building will become the headquarters of the Baptist Union of Great Britain and Ireland, now domiciled at the Mission House, in Furnival Street.

A New Primitive Methodist Church at Swindon has been recently opened in Rodbourne Road, providing accommodation for 400 persons, and new classrooms erected, the old chapel being utilised for a schoolroom. The building, which is Gothic in style, has been built with red pressed bricks for face, and Bathstone dressings, and covered with blue slates. There is a large oriel window in the front gable. The interior is seated in pitch pine, and the rostrum and the roof principals are also of this material. The windows are fitted with stained glass. Mr. R. J. Leighfield, of Swindon, was the builder, the contract being £1,151 10s.; and the architects were Messrs. William Drew (M.S.A.) & Sons, of Swindon.

Rebuilding in Lambeth.—The Ecclesiastical Commissioners have submitted to Lambeth Borough Council preliminary plans for the rebuilding of the Lambeth estate, which area is bounded on the north by the New Cut, on the east by Short Street, on the south by Ufford Street, and on the west by Webber Street. The scheme includes the closing of two streets in the area, the construction of a new road, and the giving up of half an acre for a recreation ground. There are 213 houses to be demolished, displacing 277 families, 91 lodgers, or, altogether, 630 persons, exclusive of children. The proposal is to rebuild tenement houses and cottages for the accommodation of 250 tenants.

Gladstone Memorial Chapel.—A memorial to the late Mr. and Mrs. W. E. Gladstone is to be erected in Hawarden parish church. It is proposed to remove the organ from the north side of the chancel, and to enlarge the organ chamber so as to form a chapel, in which will be placed a recumbent effigy representing Mr. and Mrs. Gladstone. It is probable that the chapel will be octagonal in form, with a groined roof and a stained glass window. Sir William Richmond is to be entrusted with the work, and the whole scheme is estimated to cost about £1,500. It will be necessary to apply for a faculty in the Consistory Court of Chester to authorise the erection.

Birmingham University Buildings.—The statement that in the opinion of the University Council the principle of selecting designs by competition could not be advantageously adopted in the case of the new University building has raised considerable feeling among some of the subscribers to the funds of the University, as well as the architects of Birmingham, inasmuch as it will entirely exclude the latter from the opportunity of testing their ability to produce a suitable design for the proposed buildings. It has, therefore, been decided to request the Chancellor of the University (Mr. Joseph Chamberlain) to receive a deputation of architects and subscribers, who will place before him reasons why he should use his influence to have the question reconsidered, in the hope that, by means of a carefully conducted competition, the best available architectural talent may be brought to the front. A requisition to Mr. Chamberlain asking him to receive such a deputation is in course of preparation.

HUDDERSFIELD THEATRE.

THE Huddersfield Theatre Royal and Opera House has recently undergone extensive alterations and improvements, re-seating, and decorating, at a cost of between £5,000 and £6,000. The carpeting of the stairs has been continued throughout the dress circle and private boxes. This carpet is in shades to match the peacock blue plush seating of the chairs (about 140 in number, and thirty-two in the private boxes), the curtains of the private boxes, and the upholstery of the ledge round the front of the dress circle. The drop scene has been painted with an Italian view and a pink and gold acanthus-leaf moulding carried round the proscenium. There are a portrait of Shakespeare and symbolic pictures of the drama, music, and comedy over the proscenium and the upper-circle private boxes. The colour scheme is of rose pink and gold in its setting of peacock blue. The promenade behind the dress circle seats at the back has reduced the seating accommodation; but it opens up means of easy egress and opportunities for moving about. The upper circle has been re-seated in peacock blue upholstery for over 200 persons. The gallery will accommoate over 600 persons. In the pit there are three rows of orchestra stalls for about seventy persons and four rows of pit stalls for over another hundred, with upholstered chairs in the former department, and armed division benches in the latter, again in peacock blue plush. New backed benches, taking up less room, allowing of a larger number, have been provided in the pit, so that over 400 can be easily seated there. Thus sitting accommodation is provided for between 1,500 and 1,600 persons, and there is ample cloak room, lavatory, and refreshment accommodation provided.

New Companies.

Dwellings Co-operative Company, Ltd.

Registered April 2nd to acquire, lay out, prepare for building purposes, and deal with any lands and property, and to carry on the business of builders, contractors, decorators, agents, &c. Capital £5,000 in £1 shares.

Landers, Ltd.

Registered April 6th (capital £5,000 in £1 shares) to carry on the business of manufacturers of and dealers in apparatus and materials for heating, lighting, ventilating, and purifying houses, buildings, &c. Registered office: 214, Vauxhall Bridge Road, S.W.

Fitton's Brick and Tile Co., Ltd.

Registered April 4th (capital £4,000 in £5 shares, 400 preference) to acquire the business carried on at Dewsbury and Ossett, Yorkshire, by J. Fitton, sen., and to carry on the business of brick, tile and pipe makers, pottery, earthenware and porcelain manufacturers and dealers, &c.

British Incandescent Heating Syndicate, Ltd.

Registered April 1st to adopt an agreement with A Smallwood and the Coventry Tube and Metal Company, Ltd., and to acquire, develop, and turn to account any invention relating to the manufacture of furnaces, muffles, and heating apparatus. Capital £35,000 in £1 shares.

H. C. L. Gas Stove, Ltd.

Registered March 28th to acquire a certain invention, and to carry on the business of manufacturers of and dealers in stoves, ranges, lamps, and other cooking, lighting or ventilating apparatus, &c. Capital £40,000 in £1 shares. Registered office: 8, Berners Street, W.

Builders' and General Foundry Company, Ltd.

Registered March 29th to acquire the business carried on at 22, Cemetery Road, Sheffield, by H. Platten, and to carry on the business of ironfounders, manufacturers of tomb railings, ornamental railings, fencing, palisading, altar rails, balusters, &c. Capital £3,000 in 200 ten per cent. cumulative preference shares of £5 each and 2,000 ordinary shares of £1 each. The first directors are S. A. Ward, H. Platten and J. L. Taaffe. Registered office: Victoria Chambers, 22, Norfolk Row, Sheffield.

Plowman & Son, Ltd.

Registered March 27th to take over the business of a brick, pipe and tile manufacturer and merchant carried on by T. S. E. Plowman at Meppershall and Gravenhurst, Bedfordshire, as E. Plowman. Capital £7,500 in £5 shares. The first directors are T. S. E. Plowman (governing director) and J. A. Plowman. Registered office · Stanpit, Shefford, Bedfordshire.

Coxhoe Limestone Company, Ltd.

Registered March 28th to acquire certain freehold estates in the county of Durham, and to carry on the business of lime burners, quarrymen, cement manufacturers, builders, contractors, limestone, lime, clay and stone merchants, &c. Capital £4,000 in £1 shares. The first directors are F. J. Bell, T. Common, L. S. H. C. Orde and H. S. Peel. Registered office: 1, St. Nicholas Buildings, Newcastle-on-Tyne.

National Association of Master House Painters and Decorators of England and Wales (Incorporated).

Registered March 27th, with 1,000 members, each liable for £1, to take over the unincorporated National Association of Master House Painters (established at Manchester in 1894), and, generally, to promote the interests of master house painters and decorators. The management is vested in a committee. Registered office: 16, Oxford Street, Chorlton-on-Medlock, Manchester.

COMING EVENTS.

Wednesday, April 24.

GEOLOGICAL SOCIETY OF LONDON. — Meeting at 8 p.m.

SOCIETY OF ARCHITECTS.—Annual Dinner at the Prince's Restaurant at 6.30 p.m.

SOCIETY OF ARTS.—Mr. Alexander Siemens on "Patent Law Reform," 8 p.m.

EDINBURGH ARCHITECTURAL SOCIETY.—Address by Mr. Harold O. Tarbolton, the Hon. President, and Award of Prizes in competitions.

INSTITUTE OF SANITARY ENGINEERS.—Visit to Building Trades Exhibition.

INSTITUTION OF CIVIL ENGINEERS.—Students' Visit to the Shipbuilding Department of the Thames Iron Works, Shipbuilding and Engineering Co., Ltd., at Works, Orchard Yard, Blackwall, E., at 2.25 p.m.

Thursday, April 25.

SOCIETY OF ARCHITECTS.—Mr. Ellis Marsland on "The Results of some Tests with Fire-resisting Materials," 8 p.m. Visit during day to Building Trades Exhibition.

ROYAL INSTITUTION.—Mr. Roger Fry on "Naturalism in Italian Painting"—II., 3 p.m.

INSTITUTION OF CIVIL ENGINEERS (Ninth "James Forrest" Lecture).—Prof. Frank Clowes, D.Sc., on "Chemistry in its relations to Engineering," 8 p.m.

INSTITUTION OF ELECTRICAL ENGINEERS.—Meeting at 8 p.m.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—Dr. Todhunter on "Some Pictures in the National Collection."

Friday, April 26.

ARCHITECTURAL ASSOCIATION.—Members' Soirée.

ROYAL INSTITUTION. — Dr. Hans Gordon on "Colour in the Amphibia," 9 p.m.

SOCIETY OF ARTS (Howard Lectures).—Mr. Alfred C. Eborall, M.I.E.E., on "Polyphase Electric Working," 8 p.m.

GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE ARCHITECTURAL CRAFTSMEN'S SOCIETY.—Business meeting at 8 p.m.

PHYSICAL SOCIETY.—Meeting at 5 p.m.

BUILDING TRADES' EXHIBITION, Royal Agricultural Hall, Islington.—Conference on Standardising of Bricks, 4 p.m.

Saturday, April 27.

ROYAL INSTITUTION.—Mr. John Young Buchanan on "Climate: Its Causes and Its Effects"—II., 3 p.m.

NORTHERN ARCHITECTURAL ASSOCIATION.—Visit to Sunderland.

Monday, April 29.

SOCIETY OF ARTS (Cantor Lectures).—Sir William Chandler Roberts-Austen, K.C.B., F.R.S., and Mr. T. Kirke Rose, D.Sc., on "Alloys"—II.

TOWN HALL, ISLINGTON.—Conference of the Housing of the Working Classes.

SURVEYOR'S INSTITUTION.—Ordinary General Meeting, 8 p.m.

Wednesday, May 1.

SOCIETY OF ARTS.—Mr. Arnold F. Hills on the "Thames Steamboat Service," 8 p.m.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—Annual General Meeting. 4.30 p.m.

EDINBURGH ARCHITECTURAL ASSOCIATION.—Annual Business Meeting and Presidential Valedictory. Addressed by Mr. Henry F. Kerr, A.R.I.B.A.

TENDERS.

Information from accredited sources should be sent to "The Editor." Results of tenders cannot be accepted unless they contain the name of the Architect or Surveyor for the work.

ACTON.—For carrying out certain work of York flagging and tar paving on the main road footpaths in the district of Acton, for the Highways Committee of the Middlesex County Council, Mr. H. T. Wakelam, county engineer and surveyor:—

J. Smart	£2,265	B. Nowell & Co.	£2,136
W. Griffiths & Co., Limited	2,182	H. Morecroft	2,090
W. Neave & Son	2,160	G. Wimpey & Co.*	2,025

* Accepted.

BOURNEMOUTH.—For works, &c. in connection with the Corporation tramways. Mr. F. W. Lacey, M.I.C.E., borough engineer, and Messrs. Lacey, Clirehugh & Sillar, consulting engineers, 2 Queen Anne's Gate, S.W.:—

Contract No. 1.—38 electric cars, &c.

Bramigh & Co.	£35,025	0
Siemens Bros. & Co., Limited	30,970	0
R. Blackwell & Co.	30,374	0
Hungarian Railway Carriage and Machine Company	30,030	0
Hurst, Nelson & Co.	29,472	4
British Thomson-Houston Company	29,364	2
Brush Electrical Engineering Company, Limited	28,381	0
British Westinghouse Electric and Manufacturing Company, Limited*	28,020	0

* Accepted.

BOURNEMOUTH.—For works, &c. in connection with the Corporation tramways. Mr. F. W. Lacey, M.I.C.E., borough engineer, and Messrs. Lacey, Clirehugh & Sillar, consulting engineers, 2 Queen Anne's Gate, S.W.:—

Contract No. 2.—Four steam dynamos, &c.

Brush Electric Engineering Company, Limited	£18,930
British Westinghouse Electric and Manufacturing Company, Limited	17,857
British Schuckert Electric Traction Company	17,453
Brush Electric Engineering Company	17,250
British Westinghouse Company	16,234
British Schuckert Company	16,145
Johnson-Lundell Electric Traction Company	16,135
Anchor Electric Company	15,900
British Schuckert Electric Traction Company	15,485
Lancashire Dynamo and Motor Company, Limited	15,406
Anchor Electric Company	15,200
Anchor Electric Company	15,100
Siemens Bros. & Co., Limited	14,890
Lancashire Dynamo and Motor Company	14,844
British Thomson-Houston Company, Limited*	14,733
Johnson-Lundell Electric Traction Company	14,283
Bow, McLachlan & Co.	14,000
British Thomson-Houston Company	13,993
C. A. Parsons & Co.	13,418
C. A. Parsons & Co.	12,531
British Thomson-Houston Company	12,321
C. A. Parsons & Co.	12,239
Siemens Bros. & Co.	12,199
Lancashire Dynamo and Motor Company	11,982
British Westinghouse Company	11,932

* Accepted.

BRADWELL (BUCKS).—For the erection of a new girls' school and alterations to existing buildings, for the Bradwell School Board. Mr. John Chadwick, architect, Bletchley:—

T. Jerrell, Linsdale	£3,989	10	0

Tramway Enterprise in New Zealand.—To the Roslyn Tramway Co., of Dunedin, belongs the honour of being the first to introduce cable tramways in the Australasian colonies. This was twenty years ago, and it is somewhat curious to note that the same company is now the first to introduce an electric tramway into New Zealand. The overhead trolley system has been adopted, and the whole of the work has been carried out by the British Westinghouse Co

Can be fixed close up to Purchaser's boundary, and suits rise or fall in the ground.

BUILDING TRADES' EXHIBITION, 1901.

SPECIAL SUPPLEMENT.

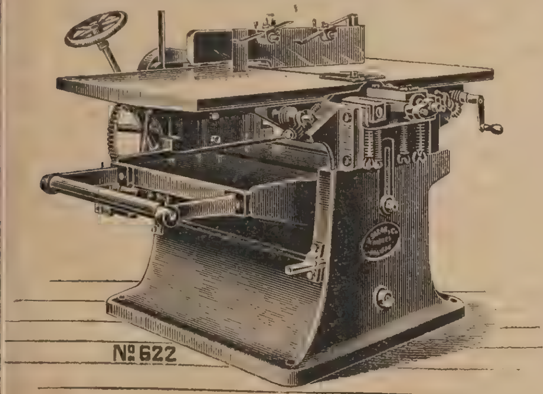
THE Building Trades' Exhibition now open at the Royal Agricultural Hall, Islington, is, as we have already stated, the most extensive of its kind yet held in this country, and we give this week a Supplement containing particulars of all the chief exhibits. This will be found of special use to those who, though interested to know all that is new in the building and allied trades, are unable to attend the Exhibition themselves. It is of course impossible for us to notice all the exhibitors, who number nearly 300, but we think that our selection will be found a thoroughly comprehensive one. This year special sections are devoted to fire prevention and smoke combustion (though the latter is somewhat disappointing), and a new feature is an exhibition of architectural drawings, in a room off the gallery.

On Thursday last a party of fifty Germans visited the Exhibition, and were entertained at a banquet by the Institute of Clayworkers. On Friday the Institute of Builders paid a visit, and the Architectural Association on Saturday, while the general public have assembled in great numbers. For further announcements see last page of Supplement.

J. SAGAR & CO.

The exhibit at Stand No. 152, Wall Space, of Messrs. J. Sagar & Co., wood-working machinists, of Halifax, is an excellent one. A number of machines are shown, of which the following are the most important :—

"Premier" planing-out-of-twist, jointing, squaring-up, moulding and thicknessing machine, for hand- and roller-feed. This is a most useful machine, as it will plane from $\frac{1}{16}$in. to 7½in. thick, and up to 20in. wide. Hand grinding machines suitable for plane irons up to 24in. long, and also for grinding all shapes of moulding cutters. Automatic grinding machine suitable for plane irons up to 26in. long. Band sawing machine, with 30in. saw pulleys and canting table. Vertical-spindle moulding and shaping machine, for working with cutters through the spindle in the French style, or with grooved collars and square cutter-blocks (the spindle is arranged to work right or left at option, and is fitted with roller-feed gear for new features in top and side-pressure apparatus ; countershaft separate from machine. Improved and two side spindles for planing and edge moulding-up to 18in. wide by 5in. thick ; three pairs of feed-rollers give a powerful straight work). Improved tenoning, scribing and cross-cutting machine, hand-feed planing, jointing, moulding, &c. machine, circular-saw bench with rising and falling table 4ft. 8in. by 2ft. 4in., suitable for saws up to 32in. diameter, new-pattern builder's power mortising and boring machine, and an improved four-cutter-planing and moulding machine for working mouldings, &c., on four sides at one operation up to 4in. by 2in. ; also a machine for planing panels, thicknessing, tongueing, grooving, moulding, &c., a double vertical-spindle moulding and shaping machine, and similar wood-working machines.



BRITISH URALITE CO., LTD.

The British Uralite Co., Ltd., of 37, Lombard Street, E.C. (Row D, Special Position No. 3), exhibit a hut constructed with the new material "Uralite," suitable for colonial and military purposes, for temporary use in connection with the housing of labourers on public works, mining corps, go-downs, sheds, &c., and for any purpose where a fire-resisting material is desirable, and where it is advantageous to keep a building cool in summer and warm in winter. It is insect-proof and cannot be injured by white ants, and it will not decay, dry-rot, mildew, or sustain damage from atmospheric change. Owing to the lightness of the material it is very portable, and therefore suitable where long and difficult transport of material is necessary. The contents of the hut show how Uralite can be veneered for panelling the interior of houses, the cabins of ships, for railway carriages, and numerous other purposes ; also how it can be painted, grained, and polished, used for parquet flooring, &c., in every case forming a fire-resisting material. In the Fire Prevention Section the firm show, different forms of partitions and ceilings in which Uralite slabs are substituted for match-boarding or plastering, with the object of rendering these partitions or ceilings fire-resisting.

The company have extensive works for the manufacture of the material near Higham, in Kent.

BROWN'S PATENT KILN, LTD.

Stand No. 129, Row F, is occupied by Messrs. Brown's Patent Kiln, Ltd., of Essex Wharf, Durward Street, Whitechapel, E. A large model of their patent continuous kiln, to burn 80,000 bricks per week, is exhibited. It has sixteen chambers constructed with vertical side walls strongly braced with steel joists and tie-rods. The material shown is manufactured by Eredi Frazzi, of Cremona. It is all in the nature of hollow brick, and is characterised by extreme lightness and great strength It has been awarded gold medals at Turin, Bozzolo, Nice, Como, Naples, and Paris. It is remarkably uniform in texture, and also perfectly true—so much so that at Paris the firm exhibited two hollow slabs, 10in. wide and 3in. thick, 20ft. in length, and perfectly straight.

Kilns are now in course of construction for the Norbiton Pottery and Brick Works, Limited, at New Malden ; for the Stourbridge Brick Company, Cambridge ; and for J. C. Edwards, of Ruabon. A Hoffmann kiln, at Bourlon in France, is in process of alteration to the system of Brown's patent.

F. McNEILL & CO.

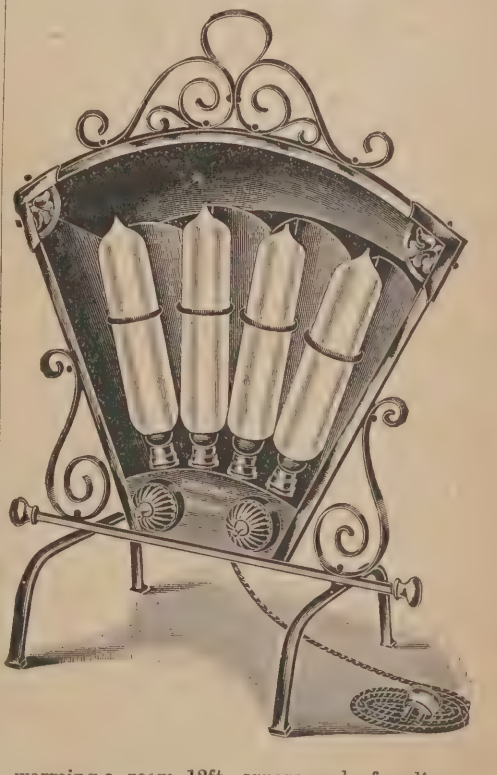
Felts, damp-course materials, slag wool and pipe coverings form the exhibit of Messrs. F. McNeill & Co., of Lamb's Buildings, Bunhill Row, E.C. (Stand No. 92, Row D). Their patent asphaltic roofing felt is obtainable in rolls 25yd. and 30yd. long and 32in. wide ; the sarking or slaters' felt is similar, but thinner. The bituminous felt is free from offensive smell, and is used for placing under roofs and for lining walls. Messrs. McNeill's patent metal-asphalt damp-course consists of sheet lead fixed between two layers of fibrous asphalt, thus being perfectly impervious to damp : a slab 4½in. by 32in. costs 6d. The approximate cost per yd super. of various kinds of damp-courses is estimated as follows : Slates and cement (two courses), 4s. 6d. ; best asphalt, 6s. ; sheet lead, 6s. to 8s. ; blue bricks, 5s. to 6s. ; tar and sand, 1s. 6d. ; fibrous asphalt, 7s. 6d. ; patent metal-asphalt, 5s. With regard to slag wool, it is a feature of this firm's system of packing that the wood joists or studs are arranged vertically and horizontally in such a way that the transmission of sound by them is greatly reduced. The firm have recently secured the order for the cold storage and insulation work on the new White Star liner, the "Celtic."

MOREAU MARBLE CO., LTD.

The claim of the Moreau Marble Co., Ltd., of 79, Lot's Road, Chelsea, S.W., is that their material is not an imitation, but genuine, marble —the production in six weeks of what Nature took centuries to make. The basis is ordinary soft white limestone, and it is in this state that all carving, &c., is done. Afterwards the stone is placed in a metallic solution in order to obtain the desired colour, which permeates the whole block ; then it undergoes a hardening process to obtain the crystalline structure of marble, and finally it is dried and friction-polished. The firm guarantee that it will wear as well as Nature's marble, though it is only one-third as costly. Specimens are shown at Stand No. 94, Row D. Messrs. Alfred Waterhouse, Paul Waterhouse and C. F. A. Voysey are among those architects who have used Moreau marble.

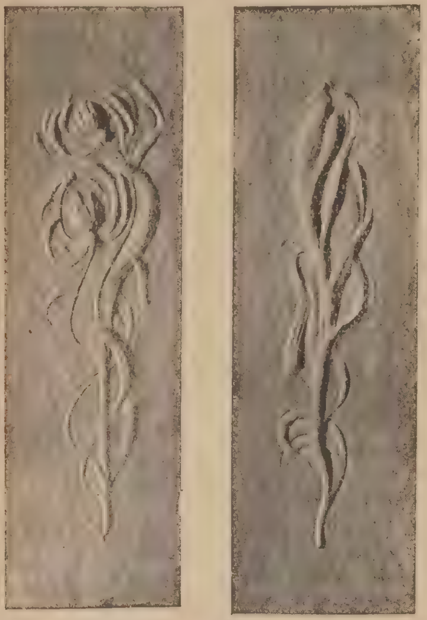
DOWSING RADIANT HEAT CO., LTD.

Stand No. 77, Row C, of the Dowsing Radiant Heat Co., Ltd. (James Melling, Dashwood House, New Broad Street, E.C.) is made very cheerful and warm in appearance by the Dowsing radiators. These consist of a back and side of copper, in front of which four electric heat lamps are fixed, being connected up in pairs so that two or four lamps may be used at will. A radiator of this kind consumes 1 unit of current per hour, and is usually found of ample capacity for warming a room 12ft. square and of ordinary height. For large rooms two or more radiators may be used (they cost four guineas each). The fact that it is possible to at once obtain warmth and cheeriness—and this without fumes, dirt, or consumption of oxygen—has secured for these radiators a large sale. Nine of them were sent to the Isolation Hospital at Leyton, and the matron has recently written to say how much they are appreciated both by patients and staff.



B. DELLAGANA & CO., LTD.

At Stand No. 74, Row C, is exhibited the new metallic decoration produced by Messrs. B. Dellagana & Co., Ltd., of 11, Shoe Lane, Fleet Street, E.C. Two panels made after this manner are illustrated below. The process consists in the exact reproduction in copper and other metals of designs in the most plastic and perishable materials—wax, plaster, &c. In conjunction with Messrs. George Roselieb & Son, of Kennington, a provisional patent has been obtained for the process of producing high-relief undercut ornamental metal work of a kind hitherto only producible by highly-skilled labour at a prohibitive cost, and arrangements have been made with competent artists by which original models, carvings, repoussé or other designs can be rendered in metal form by electro-deposition. The copper can be obtained bright, polished or of a beautiful green-bronze, and colour contrasts are easily secured; for instance, a relief ornament in bright copper can be obtained standing out from a white metal ground. The process reproduces sharpness of line and grace of curve perfectly, and is not costly.



W. HÖFLER.

Mr. W. Höfler is a maker of high-class hammered ironwork for architects, interior decorators, electrical engineers and others. Some fine specimens are to be seen at his stand (No. 64, Row C). These include finger plates, electric light and gas fittings, door and cabinet furniture, fire-irons, &c.; and particularly a very handsome large iron grille, Renaissance in feeling and well executed. Mr. Höfler also deals in art castings, French paperhangings, art fabrics, Medmenham pottery tiles (produced under the direction of Conrad Dressler), French and Austrian parquet flooring, and wood chimney-pieces and furniture, all of which may be seen at his newly decorated premises at 26A, Soho Square, W., which is part of the historic "Carlisle House" built in 1669, the town residence of the Earl of Carlisle.

MINTONS, LTD.

The exhibit at Stand No. 62, Row C, of Messrs. Mintons, Ltd, of 25, Farringdon Avenue, E.C., consists chiefly of several wall panels in coloured tiles. The most attractive are those possessing a raised outline and being painted in coloured glazes. The effect of this method of treatment is very pleasing, as the design is made more decorative and the colour scheme heightened in tone. The work is excellently carried out, both as regards design and technique, and shows that the firm are following new and improved standards in wall decoration. In the matter of tiles, as in everything else, *chacun à son goût*; and while some prefer those with a perfectly even and spotless surface, others consider the old kind of tiles—made by hand, with a spotted and uneven surface—to be the best. Messrs. Mintons make both kinds, each well. Architects visiting the Exhibition should make a point of inspecting this stand, as it will amply repay them to do so.

LONDON HOIST AND CHAIN CO., LTD.

The London Hoist and Chain Co., Ltd., of 103, Worship Street, Finsbury, E.C., exhibit their pulley blocks and other lifting tackle at Stand No. 57, Row B. The "Samson" patent double-worm pulley blocks are tested to 50 per cent. beyond their lifting capacity, and, when required, a test certificate for the chain may be obtained. This chain is of the best quality and workmanship. The hand chain-wheels are of cast steel, the frames, hooks and bolts are of forged steel, and duplicate parts are self-acting. The "Weston" differential pulley blocks made by the firm are fitted with patent roller chain guides, which prevent troublesome locking, are self-adjusting, and form a guide for every loop of chain. Four feet of chain are required for every foot to be lifted. The "Crane" patent pulley block (J. T. Pickering's system), as its name implies, is far-reaching, and is a cheap and effective apparatus for raising loads when a jib crane is not applicable; in this respect it is specially suitable for abattoirs, engine rooms, printing establishments or retort houses.

FREDERICK JONES & CO.

Messrs. Frederick Jones & Co., of 1A, Perrin Street, Ryland Road, Kentish Town, N.W., were the pioneers of that excellent sound- and fire-proofing material, slag wool, or silicate cotton. For years past they have supplied large quantities of it to the trade, and it has been used by such architects as the late Sir Arthur Blomfield in the Royal College of Music, by Mr. Mountford in Battersea Town Hall, by Mr. Alfred Waterhouse in the Clergy Orphan School at Bushey, by Messrs. Ernest George & Peto in Lord Stalbridge's mansion, and for preventing the sound passing between St. George's Hall and the Queen's Hall (about 60 tons were needed in the last-mentioned case); so that it needs little else to recommend it. The firm are now introducing a patent new system for ceilings and partitions, which consists in combining the advantages of expanded metal and silicate cotton. The cotton is firmly fixed in the metal, and the whole is then plastered in the usual way, the result being a partition which will withstand the fiercest fire and one that will not transmit the heat from one side to the other. This system should be carefully examined at the firm's stand in the Fire Prevention Section. The above illustration shows Messrs. Jones's works at Southbank, Yorks.

MESSRS. FREDERICK JONES & CO.'S WORKS AT SOUTHBANK, YORKS.

MOULE'S PATENT EARTH-CLOSET CO., LTD.

Forty years ago the dry-earth system of dealing with closet refuse was introduced by the Rev. Henry Moule, Vicar of Fordington, Dorset—at first for the benefit of his poor parishioners, and afterwards as a commercial enterprise; and there can be no doubt that earth-closets have many advantages to recommend them. Moule's patent earth-closets (to be seen at Stand No. 55, Row B) are made in eight different forms, the principle, however, being the same throughout, consisting of a tapered receptacle at the back to hold the earth and a hand lever for discharging it into the pan (each form throws 1½ pint of earth every time). The earth used must be of a loamy nature, perfectly dry and finely sifted—this is proved to be the best deodorant and the best disinfectant. Where, however, it is difficult to obtain a sufficiency of such earth, sifted ashes may either wholly or in part be used. It is interesting to note that six persons will require 1 cwt. of earth per week. The address of Moule's Patent Earth-Closet Co. is 5A, Garrick Street, Covent Garden, W.C.

J. C. BROADBENT & CO., LTD.

Messrs. J. C. Broadbent & Co., Ltd., of London, Redcar, Hazlehead, and Huddersfield, occupy Stand No. 50, Row B. One of their specialities is a patent slag-wool sectional pipe covering, which is made in 3ft. lengths for pipes up to 18in. diameter. The covering can be removed and replaced at any time, and will not crack or break. The firm's slag-wool is a pure mineral fibre manufactured from Cleveland slag, and contains a large percentage of silica and aluminia and a small percentage of free lime (which makes slag-wool liable to pulverise and settle). It is largely used for cold storage insulation and for fire- and sound-proofing ordinary buildings. For the latter a partition may consist of 2in. by 3in. struts, matchboarding to give a solid side for packing, and the slag-wool put in between wire netting. The cost of wire netting for both sides is about ¾d. per sq. ft.; and slag-wool 3in. thick about 2½d. per sq. ft. A partition of the kind described satisfactorily withstood a test lasting three-quarters of an hour made by the British Fire Prevention Committee in January, 1900.

GRANITE SILICON PLASTER CO., LTD.

Granite plaster is an artificial stone composition intended to take the place of lime and hair plaster for covering inside walls, ceilings, &c. It is manufactured in the form of a fine powdered material, put up in sacks, and is made ready for use by the addition of sand according to requirements, though for work in London a material already mixed with sand is obtainable. It is applied in the usual way, dries quickly (in twenty-four hours), and when set is "as hard and lasting as granite stone" (to quote the firm's own words). A solid partition is made with an expanded metal core covered with 2in. of granite plaster mixed with a proportion of clean sand. It will bear rough treatment without denting, chipping, cracking or loosening, will not absorb disease germs, and is rat- and mice-proof. It has been largely used by the War Office and General Post Office authorities. The firm's address is 36, King's Road, St. Pancras, N.W., and the stand is in Row B, No. 47.

EMDECA METAL DECORATION CO.

Emdeca decoration, to be seen at this firm's stand (No. 46, Row B), is made of flexible thin-gauge zinc sheets which can be cut with ordinary shears and bent around the sharpest angle without injuring the surface coating. It is specially suitable for bathrooms, lavatories, kitchens, restaurants, hospitals, &c., because it has a clean appearance and is sanitary (it can be washed with antiseptic solutions). The sheets are fixed in position by a paste made of two parts of ordinary whiting and one part of white lead, well ground and thoroughly mixed with varnish until of a slightly liquid consistency. Sheets can be applied to wood as well as to plaster, but *not* to walls or ceilings newly rendered with Portland cement. Another novelty of this firm are the American stamped steel ceilings, which can be obtained in a variety of patterns. The joints are made either with an ornamental beading in which the nails do not show, or on a small bead moulding with countersinkings at regular intervals. The trade price for these ceilings is from 2s. 6d. to 3s. 6d. per sq. yd. The company's address is 97, Queen Victoria Street, E.C.

BRITISH OPAL WALL-GLAZING CO., LTD.

Glazed goods of every description are being increasingly used in all kinds of building and sanitary work, and notice should, therefore, be taken of all novelties. One of these is the patent opal glass made by the British Opal Wall-Glazing Co., Ltd, whose works are at Stourbridge and registered office at 12, Dartmouth Street, Queen Anne's Gate, S.W. (their stand is No. 45, Row B). This material, which is intended as a substitute for glazed bricks and tiles, has a backing of the same ingredients as the material itself; and the cement used for affixing to walls, &c., is damp-proof and of a special elastic character. This slabs can be produced for w.c.'s, lavatories, &c., of any size up to 7ft. high by 6ft. 6in. wide and $\frac{3}{4}$in. thick. They are covered on both sides with British opal. The company's own productions are supplied in a variety of tints, and can be formed to bullnoses, angles, beads, &c., and architects' own designs can be executed.

CRANSTONE ENGINEERING WORKS, LTD.

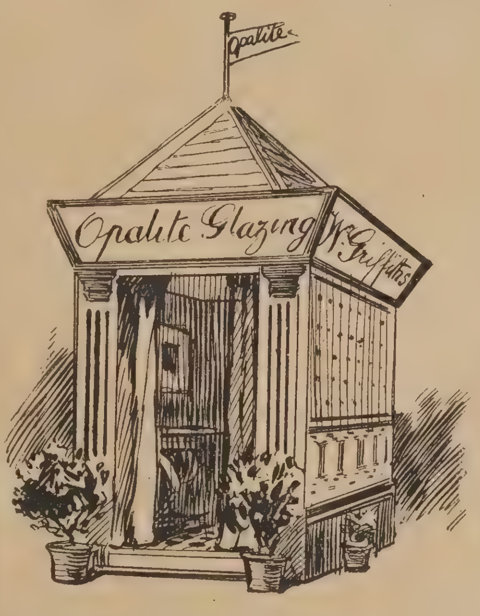
Stand 42, Row B, is the exhibit of the Cranstone Engineering Works, Ltd. (the Pickering Block and Hoist Co.), of Hemel Hempstead. Here may be seen all kinds of lifting tackle. The most recent novelty shown is a patent self-sustaining quick-speed sack hoist, which, while very rapid in action, is perfectly self-sustaining. The 3-cwt. size costs £3 10s., the 5-cwt. size £4 5s. The "Universal" friction hoist was specially designed with a view to compactness. It can be fixed in any position—on top of or below beams, vertically or horizontally—works easily and silently, and is preferably fitted with a patent automatic stop-action to prevent overwinding. The shafts run in gun-metal bearings. The "Standard" friction hoist made by this firm is worked by hand and power, being specially intended for use where the motive power is intermittent. Two other patents of the firm are the "Reliance" and "Gripper" friction clutches and "Excel" clutch lever.

OFFA VENTILATING CO.

The Offa Ventilating Co., of 63, Basinghall Street, E.C., who occupy Stand No. 14, Row A, exhibit their patent "Offa" inlet ventilator. This consists of a frame carrying an air-filter (of rough open cloth) covered by a movable face-plate on which the incoming air strikes, and is diffused all over the wall—that is to say, the air is prevented from rushing forward and creating a draught, as it issues directly from the sides of the ventilator, and so spreads itself. A model on the stand demonstrates this. No draught is perceptible within 6in. of the wall. These ventilators are made, complete for fixing, in five sizes, from 10in. by 7in. to 21in. by 18in. They can be adjusted to a nicety, or closed entirely. The whole of the interior is easily accessible from inside the room on which the ventilator is fixed, and the filter screen can be readily removed for cleansing purposes. This firm exhibits Mallable's patent bracket for fixing Venetian blinds, by means of which the blind is securely held without screws, allowing it to be taken down and replaced by one person, however inexperienced. The first cost is only 6d. per window.

NATIONAL OPALITE & GLAZED BRICK & TILE SYNDICATE, LTD.

The London concessionaire of this firm is Mr. William Griffiths, of 41, Hamilton House, Bishopsgate Street Without, E.C. (his stand is Special Position No. 8, Row E). "Opalite" is a plate or tile made from pure opal glass, in almost any colour, having a rough granular back, which is incorporated in the opal itself. It is a patented composition, of an exceedingly tough nature. One of the reasons why it is superior to the ordinary clay tile is that it sticks not only at first, but always. "Opalite" tiles form a perfect mechanical bond with the cement to which they are affixed. The material does not by exposure to damp, frost, or heat lose any of its beautiful polished surface, neither does it discolour, decay, or become patchy. It is readily repaired. Both old and new brickwork can be glazed, and the advantages of having walls glazed after the brickwork is finished are strongly urged, to secure a close joint and avoid a heavy waste in breakages. It is made in a variety of tints and sizes, and can be formed into bullnoses and angle beads. The ordinary stock sizes are 9in. by 3in. and 6in. by 6in. The reflecting power is excellent, the light being uniformly distributed. This advantage will be readily appreciated for subways, passages, basements, &c., where borrowed light is a necessity. This is the only opal glazing with a granulated back fluxed on. More than 80,000yd. of this material have been fixed by the London concession alone. It has been used at Windsor Castle, Central London Railway, Stock Exchange, and in a number of other important buildings. We illustrate above Mr. Griffiths's stand at the Exhibition, which we are enabled to do through the courtesy of the "Daily Graphic."



WALTER E. MASON.

Stand No. 90, Row D, is occupied by Mr. Walter E. Mason (late A. Mason & Sons), whose works are at Horwich, Lancs. This is the first time his goods have been shown on exhibition in London. No lead is used in the composition of any of the glazes, and all goods are made from fireclay. One of the chief exhibits is a combination lavatory and vegetable sink, 6ft. long in one piece, in white porcelain enamelled fireclay mounted on glazed pedestals with iron bases; exposed open overflows is a feature of most of his sinks and basins, facilitating convenient and efficient cleansing. Another prominent exhibit is a hexagonal urinal in white enamel with imitation marble facings. The tank at the top is fitted with automatic drop-by-drop cistern, and can be supplied with water in the form of small fountain spray, so assisting ventilation and giving an effective and pleasing appearance. This urinal (as are all others on this stand) is fitted with Mason's patent flushing nozzle, which throws a fan of water without a splash over the whole back of the stall. Treads are also provided with mosaic panels, providing secure foothold, yet impervious to moisture. Mason's patent siphonic "Maelstrom" closet is practically noiseless, and will work with 2 gall. of water. It has a 5½in. seal, a water area 12in. by 10in., and cannot be siphoned except when in use. This closet is shown under water. Closets with Mason's "Sanitary" and "Anatomical" seat pads, recommended for rough use and public conveniences, are also shown, as well as a number of baths and basins. A novel, artistic and most pleasing exhibit is the "Ruby" lavatory basin, which is oval and can be built with a corbel into the wall, or stand away from the wall on a centre pedestal. As it is Mr. Mason's intention to open showrooms in London, architects and others interested in sanitary goods should take the opportunity of inspecting these exhibits. Depots and showrooms have already been established in Manchester, Liverpool, Glasgow, Hamburg, Rotterdam, Warsaw and Cape Town.

JOHN SUTCLIFFE & SON, LTD.

Saw benches, planing machines and other kinds of wood-working machinery are to be seen at work at the stand (No. 156, Wall Space) of Messrs. John Sutcliffe & Son, Ltd., of Arden Works, Halifax. Sutcliffe's hand-planing and jointing machine (D 1) is useful for all kinds of joinery and cabinet-making. Without changing the cutters it will do planing-out-of-wind, surfacing, jointing, chamfering, rebating; while by fixing special cutters, tongueing and grooving and stick light mouldings can be executed. With these machines a very simple and effective hand-guard can be used. Its form is implied by its name—"the Boomerang." The only attachment is to a bracket fixed by a set-screw to the table of the machine. Normally it presses against the fence, covering the whole length of the cutters, but as the wood is fed forward it pushes aside the guard, which, however, still covers the cutters. Its price is 25s. complete. Three band-saws of different qualities are also shown at this stand. Some of the machines are driven by a 4 h.p. electro-motor.

JOHN TANN.

The exhibit at Stand No. 145, Wall Space, is in every way a safe one, for here are shown all the strong-room and burglar-resisting appliances of Mr. John Tann, of 11, Newgate Street, E.C. The "Anchor Reliance" safes have outer bodies made of best steel plates ½in. thick, but solid at the corners, and strengthened at the front by a steel T-frame in combination with a patent continuous interlocking wedge-resisting arrangement. The doors are of solid steel plates ¾in. thick. One of the most recent testimonials is from a firm of diamond merchants in Hatton Garden, where burglars made an unsuccessful attempt to break open one of these safes, the hardened drill-proof plate over the lock proving too much for them. Mr. Tann's party-wall doors are recommended by the Fire Insurance Committee; they are panelled on both sides with 3in. by ¼in. bars, the plates being of steel ¼in. thick.

HODKIN & JONES.

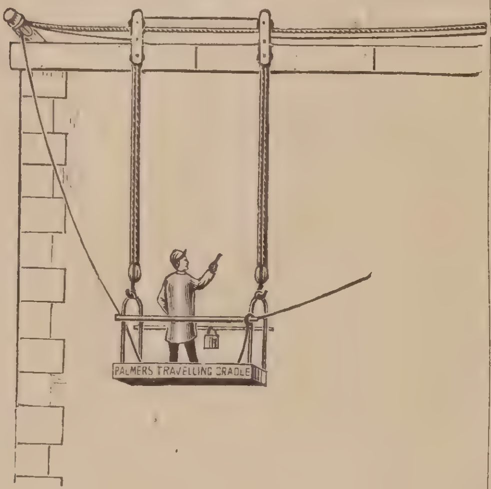
Messrs. Hodkin & Jones, of Havelock Bridge Works, Queen's Road, Sheffield, exhibit at Stand No. 118, Row F. They execute all kinds of mosaic and terrazzo work, paving in the latter being laid from 7s. per yd. super. The firm is, however, devoting special attention to concrete masonry or artificial stone, such as staircases, moulded cornices, columns, heads and sills, balustrading, &c., specimens of which are exhibited. Messrs. Hodkin & Jones claim that their masonry is practically imperishable. does not flake or crumble, of even texture, uniform colour and high-crushing strain, and is fireproof. The material has been largely used in many large buildings throughout the country, especially theatres. The offices and works of the firm at Sheffield occupy three acres of ground.

YATES, HAYWOOD & CO.

Some very pleasing mantles are exhibited by Messrs. Yates, Haywood & Co., of 95, Upper Thames Street, E.C., at their stand (No. 141, Wall Space). Several of these follow standards first set up by the arts and crafts movement, and the designs show a careful treatment; though simple, they are very effective. Some are in iron painted white, with black hoods and plain tiles at the side and on the hearth of a soft green tint, while others are in wood of various kinds—chiefly oak and walnut. A prominent exhibit is a large mantel in rosewood with side pillars, an effective piece of work. Registers, stoves, fenders, the patent "Quadrant" kitchener (in action) and the patent "Guinness" self setting range are also to be seen at this stand.

PALMER'S TRAVELLING CRADLE, LTD.

In Bay No. 2 Messrs. Palmer's Travelling Cradle, Ltd., of 250, Westminster Bridge Road, S.E., are again exhibiting their "Builder's cradle." This apparatus, illustrated on this page, is a small light cradle suspended by falls from specially constructed blocks, which travel along a wire rope or cable—the whole being so simple, light and easily worked that the cradle is taken all over the surface of the wall or front worked upon by the men working in the boat. "Palmer's" exhibit comprises a full-sized cradle fixed at each front of the stall on a cable with a 23ft. run, and gives an exact representation of the appliance as ordinarily fixed; and a visit to "Palmer's" stand will at once demonstrate why this useful invention has so quickly achieved such striking success. Another of this firm's exhibits is a "travelling scaffold," which is likely to be of great use to the trade. This "scaffold" consists of four ladders as standards securely-braced together by adjustable wire stays, and carrying a stage 9ft. by 6ft., the whole constructed on a movable platform. Each part is easily detachable, thus rendering the apparatus very portable; whilst when erected it is perfectly rigid and secure, and readily moved from place to place without dismantling. A unique feature of Palmer's business is that, by arrangement with The Accident Assurance Co., they insure the hirers and their workmen against all accidents occurring to or caused by the cradles whilst the workmen are working in them.



J. A. KING & CO.

This firm is exhibiting their "Mack" patent fireproof and soundproof slabs and blocks at two stands—No. 49, Row B, and No. 18 in the Fire Prevention Section. This invention is a very valuable one, and the exhibits should be seen by everyone visiting the Exhibition, as so much attention is now being devoted to fire prevention. The "Mack" slabs have hollow reeds embedded in a specially prepared plaster, thus forming air chambers making the slabs more soundproof, and in addition strengthening the slabs and enabling them to be sawn and nailed like boards. Fireproof partitions may be fixed of almost any length without intermediate supports with the 2in., $2\frac{3}{4}$in., and 4in. (hollow) slabs. The slabs are 12in. wide and 6ft. long, and are built up, like brickwork, with a break joint, and finished with a coat of plaster. Partitions are also erected with the 2in. vertical hollow block which requires no finishing coat, the blocks having smooth faces on both sides. For floors hollow "Mack" slab lintels are placed on the bottom flanges of iron joists, and over these are spread a layer of sand and then about 2in. of concrete. Hollow pugging blocks, $2\frac{3}{4}$in. and 4in. thick by 3ft. 6in. long, are made for placing between wood joists The ceiling and lining slabs are 12in. wide, 4ft. 8in. long and $\frac{3}{5}$in., $\frac{4}{5}$in., 1in., and $1\frac{1}{4}$in. thick, and merely require nailing to the joists with galvanised iron nails, and the whole floated and set with plaster. Thin slabs, with a damp-proof backing, are also made for lining damp walls. As a proof of the extraordinary fire-resisting qualities of these slabs we need only refer to the test made by the British Fire Prevention Committee for one hour and fifteen minutes on a $2\frac{3}{4}$in. slab partition to a temperature of over 2,000 degs. Fahr., followed by the application of water from a fire-hose. The partition was found intact after the test. The address of Messrs. J. A. King & Co. is Bridge House, 181, Queen Victoria Street, E.C.

G. TUCKER & SON.

At Stand No. 132, Row F, will be found a good show of specimens of clay work for elevations. A particular feature is the architectural work in red or buff terra-cotta, and hard bricks for sewers, manholes, &c., for which Messrs. G. Tucker & Son, of Loughborough, Leicestershire, are so well known. Most of their exhibits are specimens of work from buildings in progress, and not goods specially manufactured for exhibition. This stand is well worthy of the attention of architects, surveyors and builders, who can be assured they will get materials equal to those shown.

NUNEATON ENGINEERING CO.

The chief exhibit at the stand (Bay No. 14) of the Nuneaton Engineering Co., of Nuneaton, is Stanley's mutiplex vertical-die tile-press, which has a capacity of 5,000 an hour. It has ten dies, so that ten tiles are made at each revolution, the pressure being on the end and not on the face of the tile; the faces are glazed as the tile is ejected from the die. It is claimed that sharper arrises, closer density and finer finish are obtained than is possible with any other press, while the cost is ten times less and the output ten times greater. Stanley's "Twentieth Century" brick machines (semi-dry process) have a capacity of 8,000 bricks in ten hours for a single press. The "Twentieth Century" top and bottom hand brick-press is also shown at this stand, as well as an ingenious machine for compressing the sockets of clay pipes.

LIBRARY SUPPLY CO.

Of late years, chiefly as the result of American enterprise, library and office fitments have undergone considerable change. The roll-top desk has come to stay, and the numerous varieties of file cabinets are a great advance on the old-fashioned methods. Up-to-date fittings of this kind are the speciality of the Library Supply Co., of 181, Queen Victoria Street, E.C. (Gallery Bay, No. 23). The card-indexing system enables all sorts of new matter to be added, or old matter withdrawn, without disturbance. With this system only one thing is dealt with at a time, every single item having a separate record and place. The index consists of a series of cards, printed and ruled according to the nature of the matter to be indexed, arranged alphabetically or otherwise in trays or drawers. The cards are placed in rows on their edges, and are kept in place by a rod. All kinds of cabinets on this system are shown. A large assortment of desks, chairs, and other office and library furniture is also shown.

THAMES BANK IRON CO.

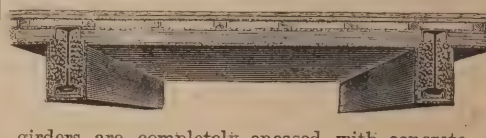
Bay No. 6 is occupied by the Thames Bank Iron Co., of Upper Ground Street, E.C. This firm is now making a speciality of iron pipes and connections for sanitary work. These are coated with Dr. Angus Smith's solution, and can be obtained in a great variety of patterns to suit all kinds of joints. Bends with inspection covers can be had with bridle and screw fastening for covers instead of bolts. A number of "Hamilton" radiators for hot water or steam are exhibited at this stand. These are put together with the smooth steel nipple, which does not need packing. The lower portion of each loop of the radiator has flanges cast on the sides, and when the loops are connected together the flanges meet and form large flues up which the cold air from outside passes and is warmed before entering the room.

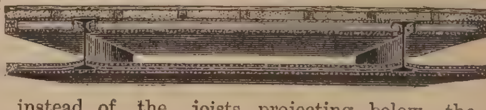
RIPOLIN, LTD.

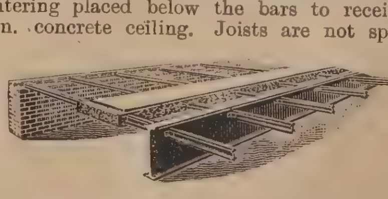
Some very satisfactory specimens of painting with "Ripolin" are to be seen at Bay No. 3. This paint can be obtained flat or glazed; and it is claimed that as it possesses extra covering capacity (with 1 gal. about 65 sq. yds. can be painted one coat) and great durability, it is for all industrial purposes cheaper than other paints—that it saves labour, and has a finish equal to the best varnish. It can be used for outdoor as well as for indoor work, as it will not scale off and is unaffected by smoke and dust. Specimens of tin coated with "Ripolin" can be examined at the stand and twisted any way to show that the material does not crack. The "flat" finishes very smooth and can be washed down. The material has gained numerous awards, and it is interesting to note that the new Alexander III. Bridge at Paris has been painted with it, after tests with various paints. The London office of the firm is at 110, Fenchurch Street, E.C.

COLUMBIAN FIREPROOFING CO., LTD.

The form of floor construction adopted by the Columbian Fireproofing Co., Ltd., of 37, King William Street, E.C. (Stands Nos. 2 and 3 in the Fire Prevention Section), is finding an increasing market in this country. The system consist of special ribbed steel bars, from 1in. to $2\frac{1}{2}$in. deep, suspended from steel stirrups over steel joists, with $3\frac{1}{2}$in., 4in. and 5in. heavy ribbed bars between the main girders or resting on the walls. These ribbed bars are entirely surrounded with concrete made of the best Portland cement, sand and furnace slag or cinders. In panelled floors, as illustrated below, all the joists and main girders are completely encased with concrete, and the underside is protected by slabs of concrete having an air-space and being secured with concealed anchors. The double construction, as illustrated below, is similar; but instead of the joists projecting below the ceiling line, 1in. ribbed bars are laid on the lower flange of the joist, and a wooden centering placed below the bars to receive a $2\frac{1}{2}$in. concrete ceiling. Joists are not spaced further apart than 7ft. This construction is particularly adapted for high buildings and heavy floors. Great economy is effected by the use of these ribbed steel bars in place of rolled steel joists, while there is also a saving in concrete.







HOBBS, HART & CO., LTD.

Messrs. Hobbs, Hart & Co. Ltd., of Arlington Street, Islington, N., have their stand in the Fire Prevention Section, No. 30. They show a good selection of their fireproof doors and safes. A special feature is a "Seamless" steel safe constructed for the storage and security of deeds on parchment. It is claimed that no safe can be properly called fire-resisting unless it is protected by chemicals, which give forth a great volume of vapour when heated by the fire. This vapour is destructive to parchments, and it is claimed that Messrs. Hobbs & Co.'s safe is the only one made for their adequate protection. The parchments are placed in an inner wooden safe, which is so constructed that unless the inner door is closed the outer one will not shut. The "New Century" mortise night lock is also shown. This is a new lock, strong and of very neat appearance, and works with a very small key, quite a pleasure to use after the ordinary immense door-key. The latch can be secured, open or shut, by just turning a knob from the inside. It should be seen to be appreciated. The patent panic bolt shown works without any springs and is most simple in action.

THE NEWELLITE GLASS TILE CO., LTD.

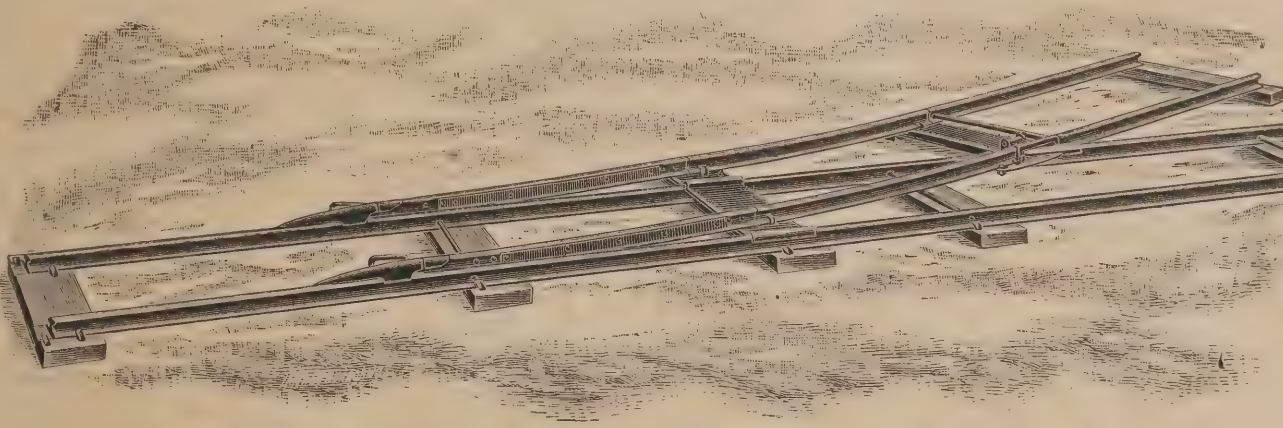
The "Newellite" opal glass tiles are now so well known that they need no special description on our part. The rough backing used is a hard one, and forms a very good key for the cement by which the tiling is fixed. One advantage claimed for the backing is that it forms an elastic film between the glass tile and the cement, allowing either substance to contract or expand independently of the other. The backing being hard, it is claimed that heat will not soften it and cause the tile to come away from the wall, as might happen with a soft backing. The patterned glass tiles shown have a most beautiful effect in their dead colours, and should meet with general appreciation. The address of the company is 139, Cannon Street, E.C., and the number of the stand 44, Row B.

REMINGTON WABASH CO., LTD.

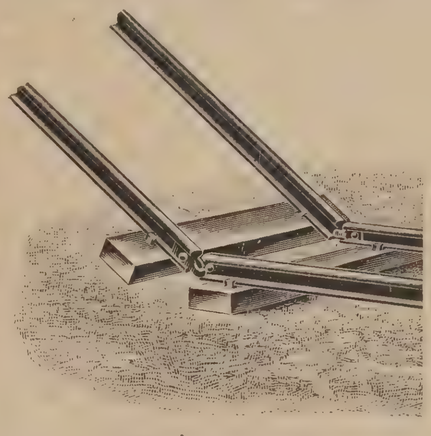
The Remington Wabash Co., Ltd., of 100c, Queen Victoria Street, E.C. (Gallery Bay 29), display a number of the latest up-to-date American labour-saving office appliances and fittings. Prominent amongst these are the Wabash letter-filing cabinets, the only side-opening drop-suspended filing tray on the market. The Wabash card-index system, for tabulating and recording information, has a folding rod which allows the card to be withdrawn from any part of the tray without inconvenience to the user. The Wabash expansion business systems, embracing letter files, card-index trays, document and catalogue files, &c., made up in sections, can be increased from a small beginning, either horizontally or vertically, to any extent. Briefly, the system is explained in these words: "Always complete, yet never finished." Wabash expansion bookcases, designed and worked on the same principle as the expansion business system, are also shown, as well as the Rem-Sho typewriter. The "Perfect" roller-copying bath, the "Racine" lever-press, roll-top desks, chairs and many other fittings complete the exhibit.

H. R. GRIFFIN & CO

The stand of Messrs. Hugh Reid Griffin & Co., of 1, Finsbury Square, E.C., in Bay No. 8, is a most interesting one. The hook joint for portable railways illustrated on this page is a very convenient one on broken land or very soft soil. The two hooks at one end of the frame are engaged behind the two pivots provided at the other side of the other end of the frame previously laid. Thus a strong joint is formed without bolting or fishing, preventing the separation of the single sections, even under heavy loads on the softest ground. The inclined plane or rising switch, also illustrated on this page, is undoubtedly of great use for branching off temporarily from a portable or permanent main line to a side track. The switch is placed direct on the track without it being necessary to take out any frame or section, and does not interrupt the main line. The wrought-iron turntable shown is most simple in action, and can be cleaned by simply lifting off the flat table plate, which works on rollers underneath. The all-round tipping waggon is a most useful contrivance, and is now well known. A rack brick-car is shown, fitted with roller bearings. These bearings have the advantage over ball-bearings that the pressure is distributed evenly all along the roller. Messrs. Griffin & Co. show Luther's tool grinder, an American invention just introduced into this country. This is made for working either by hand or by pedal. Luther's "Ideal" drilling attachment is also a most useful invention, being superior to the common breast-drill, as the pressure is given by a chain.



MESSRS. H. R. GRIFFIN & CO.'S INCLINED PLANE OR RISING SWITCH.



GRIFFIN'S HOOK JOINT.

MURAL AND DECORATIONS SYNDICATE, LTD.

Stand No. 6 in the Fire Prevention Section is occupied by the Mural and Decorations Syndicate, Ltd., of 13 and 14, New Burlington Place, Regent Street, W. The chief feature of this system is a wired lathing covered with cross-shaped pieces of terra-cotta burnt on at the joints. For walls, this material is stretched between iron rods, and is then plastered. A floor constructed by this syndicate was tested by the British Fire Prevention Committee about a year ago. The test lasted an hour and a quarter, and it was found that though various cracks developed in the plaster of the ceiling, no portion of the rendering fell. When water was applied, the plaster fell off when struck by the jet, exposing the lathing, but this latter remained intact and unaffected by the fire. After the test was concluded, it was determined that the ceiling should be re-plastered and the test renewed for one hour on a subsequent date; this was done, with the same results. This was the first continuation test made by the Committee to show the effect of fire on repaired work.

THE MOSAIC MANUFACTURING CO.

The floor space of this stand is covered with Roman marble mosaic and parquetry. Samples are shown of Venetian marble mosaic, with curved skirtings, and slabs for wall lining of this material. There are also a number of designs showing various floors recently executed, and sketch designs showing treatments for mural decoration in Venetian glass mosaic, of which there is a sample containing gold mosaic. The firm have recently taken up the manufacture of parquetry, of which far too little is used nowadays. The firm's catalogue gives some useful information about mosaics and parquetry, and a copy should be asked for. The address of the Mosaic Manufacturing Co. is 119, Pentonville Road, N., and the number of the stand is 51, Row B

LYTE'S METALLIC WOVEN STAIR TREAD CO., LTD., and BANNER SANITATION CO.

Stand Nos. 40 and 41, Row A, is a joint one for these two firms, whose address is 24, Craven Street, Strand, W.C. Lyte's metallic woven stair tread is formed of woven steel wire strands and lead. It is claimed that by the method of manufacturing this tread, the advantage of the non-slipping and noiseless lead surface is retained; while the disadvantages of rapid and uneven wear, of being pushed out of shape and forming projecting lumps on the edge of the stairs, usually associated with lead covered treads, are avoided.

The Banner Sanitation Co. show their well-known "Safe Guard" valve closets, drain stoppers for applying smoke tests to drains, and testers. A special feature is the manhole and cesspool covers, the surface of which can be fitted with a non-slipping surface of wood cubes or concrete or tar paving. The method of locking the manhole covers to the frames is ingenious, and avoids the danger of drain air passing through bolt holes, as in the ordinary style, by making the gunmetal screw bolts outside the seal.

JOSEPH HAMBLET.

Mr. Joseph Hamblet, Eagle Engineering Works, West Bromwich, occupies Bays Nos. 19 and 20. The machines made at his works are at present turning out in England alone about one thousand million bricks annually. One of his specialities is a brickmaking, pugging and grinding plant suitable for light clays, requiring only a little grinding. It is fitted with automatic winding apparatus. Another speciality is a powerful frictional-driven brick press, with which a pressure computed at about 100 to 120 tons can be given. It is particularly suitable for bricks that have to stand great pressures or are subjected to heavy wear, and the machine easily presses 4,000 bricks a day. Howl's patent brick and plastic drier, also to be seen at this stand, is operated by live or exhaust steam. The bricks are placed on hollow trays, through which the steam passes, no tunnels, fans or special machinery being needed.

WOOD CARVING CO., LTD.

The Wood Carving Co., Ltd., of Windsor Street, Birmingham, have a noteworthy stand in Row C, No. 71. This firm are showing their several specialities, such as the Saracenic twisted and turned mouldings, which are interlaced in Moorish style, and have been extensively fitted up in hotel and billiard rooms, smoke rooms, &c. These twisted mouldings have been largely used for screens of all kinds. Also a number of pressed and carved mouldings are exhibited, with carved-wood panels, newels, balusters, &c. Overdoors of every shape and kind are made by the Wood Carving Co.

JAMES WOODWARD, LTD.

Messrs. James Woodward, Ltd., of Swadlincote, at their stand in Row C, No. 79, have a large and varied exhibit of their well-known "Anchor brand" specialities, such as "Ewing's patent Xentric shoulder" socket pipe. This "fast stopper," burnt into the socket of the pipe, may be easily removed when the connection requires to be made to the sewer. It saves contractors the labour of cementing in the stoppers, and while in the whole length of sewer may be tested. "Ewing's Xentric" shoulder pipe No. 2 is for grouting in the joints in water-logged ground. A large photo is on exhibition of a long line of "Xentric" pipes laid at the drainage works, Great Ouseburn, Yorks. Woodward's "Archer" joint pipes are also worthy of notice. A good exhibit is the bottom of a manhole constructed of Freeman's white glazed blocks, which includes not only the channels for the various inlets, but the "benchings," so presenting a glazed surface to the sewage where hitherto rough cement work was usually worked in. A special feature is made of Woodward's glazed bricks in various art tints. One or two London terra-cotta garden vases containing beautiful palms add greatly to the attraction of the stand.

BANKS' FIREPROOF CONSTRUCTION SYNDICATE, LTD.

The exhibit of Messrs. Banks' Fireproof Construction Syndicate, Ltd., of 71, Queen Victoria Street, E.C., will be found at Stand No. 13, Row A. Bank's patent helical metal lathing is made of flat steel wire or ribbon, twisted and woven into meshes of convenient size. The advantages claimed for it are that the amount of metal used is the minimum consistent with the required strength, that its key is perfect and uniform under all circumstances of fixing, can be made of any required length or width, is not formed of iron sheets, which are liable to expansion and rust, and does not cut the hands. This lathing is used in Bank's method of fireproof construction for protecting the undersides of girders, joists, columns and stanchions with fireproof plastering. The method is also useful for protecting walls from damp and for partitions. A remarkable evidence of the strength of this wire lathing is afforded at the stand, great weights being supported on the thin woven strands. The lathing can be most advantageously used for embedding in concrete slabs, adding immensely to their strength. The advantage gained for Bank's lathing over sheet lathings is that, these latter, being of sheet metal must be of soft steel, whereas Bank's is made of hard steel of far higher strength, while the peculiarity of the key induces the plaster to cover the whole of the metal, thus securing it against rust and corrosion.

EXPRESS CONTRACT CO., LTD.

We are pleased to find the now familiar characters "N.A.P." still to the fore. The well-known specialities which enable casements, sliding-sashes, fanlights, &c., to be cleaned from inside the room with safety, are to be seen at Special Position No. 5, Row F. In addition there are several new specialities which are well worth the attention of all supporters of N.A.P., and which bear witness to the continued enterprise of the N.A.P. Window Company in connection with every detail or contrivance for adding to the efficiency of windows for every type of building. The number of windows fitted with N.A.P. specialities is legion, and comprise most of the leading hotels, hospitals, schools and public buildings which have been erected during the past few years. The fact that upwards of 10,000 N.A.P. windows have been fitted in schools throughout the United Kingdom is alone sufficient to justify their adoption, for if they are capable of standing the wear and tear of school conditions they will stand anything. The N.A.P. Window Company exhibited at the Paris Exhibition of 1900, and secured a medal and the highest award for windows. It is interesting also to note that these metal casements were used in the British Royal Pavilion. We hear that during last year some thousands of N.A.P. (inward and outward opening) metal casements were fixed in various buildings, including St. Gabriel's College, Camberwell (where 1,600 N.A.P. metal casements are in use). Other buildings for which N.A.P. window fittings have recently been supplied are the London Hospital; Kingsley Hotel; Abbess Grange, Hampshire; Southampton Hospital; Dorking Hospital; Victoria Hospital, Folkestone; Gifford House; Napier Barracks, Shorncliffe; and Princess Christian's Home, Pirbright. Address, 159, Victoria Street, S.W.

MATTHEWS & YATES, LTD.

Messrs. Matthews & Yates, Ltd., Cyclone Works, Swinton, Manchester, who exhibit at Stand No. 161, Wall Space, make a speciality of sawdust and shaving collection machinery. The small installation exhibited at this stand shows how refuse from wood-working machinery can be collected and deposited conveniently for consumption in steam boilers. The work is done by one of their blower-type fans, driven by an enclosed electro-motor of their own make, in conjunction with a "Cyclone" dust collector, the fan and the collector being connected by trunking. The fan is also used for assisting boilers with either forced or induced draught, not only for steamships, but also for land boilers in electric light stations, mills and various other buildings. Besides being makers of ventilating machinery, the firm have branched out into the electrical trade and are now putting motors and dynamos on the market. Their enclosed motor, of which they make a speciality, is guaranteed dust-, damp- and fireproof. Messrs. Matthews & Yates have installed their apparatus in many of the leading hotels, restaurants, post-offices, workshops and public buildings throughout the country. Their London showroom is at 84, Gray's Inn Road, W.C.

ACME WOOD FLOORING CO., LTD.

The Acme Wood Flooring Co., Ltd., occupy a large stand, Nos. 9 and 10, in the gallery. Here are exhibited specimens of wood-block flooring in maple, oak, pitch-pine, Jarrah, teak, Kauri pine, red gum, Swedish red wood—all laid on W. Duffy's "Immovable-Acme" principle. The object of this system is to prevent the loosening of the blocks. It consists of a method of dowelling by which the blocks are fixed securely to each other and the whole screwed to binding blocks secured in the foundation. The blocks are not weakened by this system. The exhibits are all laid in the firm's well-known "D" quality. With regard to street-paving, the Duffy method of laying the blocks affords a smooth level surface which increases the "life" of the pavement; this was shown in the case of the Tower Bridge, where the ordinary wood blocks had to be renewed, while the dowelled paving has been down for six years, and has every appearance of lasting many more years.

G. A. WILLIAMS & SON.

Stand 32 in the Fire Prevention Section is occupied by Messrs. G. A. Williams & Son, of 21, Queen's Road, Bayswater, W. The chief exhibit is the "Williams" fire-blind. It has over and over been proved in cases of fire that had certain openings in passages been protected or covered up, the spread of the flames would have been very greatly checked. In London alone during the past ten years there have been at least seven great fires which have proved disastrous through this defect. After the great Cripplegate fire of 1897 a special inquest was held by the City authorities, and a recommendation was made by some of the experts that it was advisable for all windows looking on to streets or light areas to be protected by a fireproof rolling blind, fixed outside the windows. The "Williams" blind fulfils the requirements. It is of asbestos, with pockets at the back to hold water, and in case of emergency can be let down in a few seconds without opening the window. It has an automatic attachment at its base to prevent flames being drawn up behind it, and is free from complicated parts. When subjected to the tests of the British Fire Prevention Committee, it effectually resisted the flames, which did not penetrate it, though the fire was a fierce one and was maintained for half an hour.

CRITTALL MANUFACTURING CO., LTD.

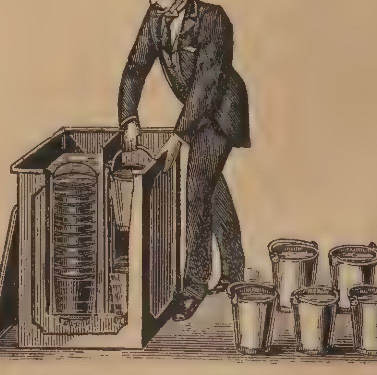
The "Safety" window casements are a prominent feature of the exhibit, on Stand No. 29 in the Fire Prevention Section, of the Crittall Manufacturing Co., Ltd., of Manor Works, Braintree, Essex. These may be of gunmetal, and have a double-hinge arrangement to enable the window to be reversed so that the outside may be cleaned with ease. The second hinge is in the centre of the frame, and can only be used after a sliding catch in the edge of the frame has been released. The fittings to these windows are of gun-metal and are well finished. The "Safety" casements have been used throughout the Record Office in Chancery Lane, at Liverpool Street Station, Liverpool Fire and Police Station, and by the late Sir Arthur Blomfield in Church House, Westminster, and the Royal College of Music.

HUNT & FAGE.

At Stand No. 39, Row A, an interesting exhibit is given of the scaffold fixer made by Messrs. Hunt & Fage, of 62, Malvern Road, Dalston, N.E. This device is undoubtedly a great saving in both labour and money on the ordinary system of fixing ledger braces or puncheon poles to standards with scaffold cords and wedges. It is simply and easily fixed to the poles by means of a chain and bolt, and is used with the ordinary poles. A very great feature in this labour-saving appliance is that in striking a scaffold the whole can easily be dismantled and let gently down to the ground by simply slacking out the chains, every pole being let down by its own gravity; thus accidents would be greatly diminished by its use. We must commend Messrs. Hunt & Fage for showing their invention in an unpretentious manner, using ordinary poles showing the action of the invention as in actual work.

MESSER & THORPE.

Messrs. Messer & Thorpe, of 8, Quality Court, Chancery Lane, W.C., show at their stand in Row F, No. 127, their patent bucket fire-extinguisher. This very valuable invention consists of a covered reservoir of water in which is submerged one or more nests of fire buckets, stored telescopically, as here illustrated. Ten, twenty, or thirty fire buckets full of water are thus always ready, and after each nest of ten has been withdrawn, five of the buckets can be refilled from the remaining water. The buckets are secured against sticking, and are withdrawn full of water. The cover of the tank prevents evaporation, and keeps it pure and free from freezing, as happens with exposed buckets. Water so protected may remain in the tank twelve months without being changed.



WALL-PAPER MANUFACTURERS, LTD.

The speciality of this firm is the "Salamander" fireproof ceiling decorations in relief. At the stand in Row B, Special Position No. 9, examples of pleasing design are shown of these well-known wall and ceiling decorations. The material is pressed out of a single sheet under great pressure, and the remarkable fact is that such a high relief as 4in. has been obtained beyond that attempted by other somewhat similar products. The sheets when fixed are painted or distempered to any required tints, and are cheap, clean and fireproof. The address of the firm is 158 and 160, Charing Cross Road, W.C.

PETRIFITE, LTD.

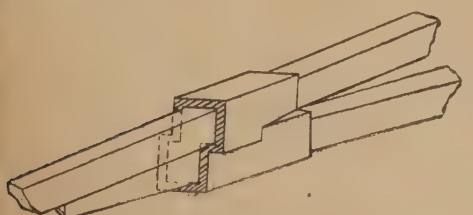
The exhibits at the stand of Messrs. Petrifite, Ltd., of 24, Finsbury Square, E.C., in Bay No. 4, consist of samples of the products of petrifite cement and petrifine, such as building stones, paving slabs, fire- and sound-proof partitions and flooring slabs, sawdust floorings and steps, pipes, utilisation of waste products, &c. From this tabulation it will be seen to what varied uses "Petrifite" lends itself, cementing as it does almost any material. A speciality of this firm is the petrifite road cement for road and street paving in place of asphalt, wood, granite, &c., its great advantage being that it sets quickly and will allow of traffic over it in a comparatively short space of time. "Petrifine Internal Cement" differs from all other internal cements, such as Keene's, Parian, &c., in having magnesium and not gypsum for its base. It works well by reason of its "fatness," and it has the great advantage that one coat can follow the other, so that the work can be commenced and finished in a day.

ST. PANCRAS IRONWORK CO., LTD.

The St. Pancras Ironwork Co., Ltd., of 171, St. Pancras Road, London, N.W., have their stand in Row B, No. 58. A model of their improved stable fittings and the prismatic and other pavement lights are especially noticeable. The glazed cellar flaps are a very great improvement over the old style ones, which are so heavy to lift; the patent systems of balance and cushions entirely does away with objections to the former kind. The prismatic window glazing is also of equal advantage, the form of the glass prisms deflecting the light in the best way. There are also on exhibition iron staircases, straight and spiral.

THE ASBESTOS AND ASBESTIC CO., LTD.

The Asbestos and Asbestic Co., Ltd., of 27, Billiter Buildings, Leadenhall Street, E.C., are showing at Stand No. 13, in the Fire Prevention Section samples of Danville asbestic fireproof plaster. Among other interesting exhibits here, one of great value to, and worthy of, the notice of builders and contractors is to be seen in Mr. F. M. Davids' patent scaffold attachment illustrated on this page. This is a very simple contrivance whereby all ties and split heads are done away with, and a secure elevation for the scaffolding of any height can be reached in less time than it takes to tie any two poles together. The simplicity of the arrangement is so surprising that it is a wonder that no such idea has ever struck a practical builder before. The claims for this invention are (1) easiness of fixture in that it can be fixed in less time than any two poles can be tied together, (2) adaptability to any elevation, (3) durability and safety, and (4) economy of time, labour and expense.



ASPINALL'S ENAMEL, LTD.

Messrs. Aspinall's Enamel, Ltd., of New Cross, S.E., have one of the best stands in the Exhibition in Row D, Special Position No. 10, consisting of a small villa model, decorated entirely with the specialities of the firm. Aspinall's enamel is too well known and widely used to need any description, but we may, perhaps, tabulate its special advantages: (1) Brilliant gloss and perfect surface, (2) easy flow and manipulation under the brush, (3) decreased cost of labour, (4) enormous covering properties, and (5) though usually supplied in the white, it may be tinted by ordinary stainers or made to match any pattern. All orders should specify if the enamel is required for *inside* or *outside* use, the distinguishing labels for which are marked respectively "*O*" and "*Indian.*"

THE NEW EXPANDED METAL CO., LTD.

This firm has stands in Row D (Special Position No. 7), and the Fire Prevention Section (No. 5). Expanded metal has now made such strides in gaining public favour that it would be needless for us to enlarge upon its advantages. The fine mesh lathing is chiefly used for plastering, and the mistake is easily made of getting too small a gauge to properly hold the plaster, which falls through the mesh and is wasted. The larger meshes are very useful in concrete flooring and adds immensely to the strength, as can be seen from the important and conclusive tests that have been carried out. The larger meshes are also used for fencing and enclosures of all kinds. The metal lathing is much used for protecting stanchions, girders, joists and columns against fire, and excellent results have been got under tests by the British Fire Prevention Committee. A novel use for the material is shown at the stands, namely, for waste paper and letter baskets made of Japanned expanded steel and polished and lacquered brass. A sand riddle of expanded metal is also shown. The address of the company is 39, Upper Thames Street, E.C.

CANDY & CO., LTD.

Messrs. Candy & Co., Ltd., at their stand in Row E, Special Position No. 4, are showing a varied assortment of granite vitrified paving, engineering, buff terra-cotta facing enamelled and glazed bricks, vitrified channelling and kerbing blocks, firebricks and tiles, terra-cotta, and stoneware pipes and fittings. A noteworthy speciality of this firm is the buff vitrified paving bricks, made solely from granitic clays. These bricks are stated to be rapidly replacing the vitrified blue brick and other pavings. They possess the advantages of being bright in appearance, are impervious, resist a crushing strain of 445 tons to the foot, are damp and frost proof and vitrified throughout. The bricks, channelling and kerbing blocks have been adopted by the War Office authorities; and on account of the sharp points of infusible silica contained in the granitic clays the paving does not become slippery in wear. For such work as stables we would recommend the bricks with longitudinal grooves, as they undoubtedly can be kept clean more easily than the herring-bone or other fancy patterns, and, after all, cleanliness is one of the first conditions of a stable. We would draw special attention to this firm's white and coloured glazed bricks. Owing to the clay these are made of their surface is not level, but rippled as it were, almost unnoticeable. This, however, far from being a disadvantage, gives a most pleasing effect, the light playing on the different angles of the surface and avoiding a deadly monotony. We noticed especially a brick enamelled a lovely dark green colour, that we would like to see employed largely; green is such a pleasing colour, and the shade made by Messrs. Candy & Co. is a grand one. The works of the firm are at Heathfield Station, near Newton Abbot, S. Devon.

CLOISONNÉ GLASS CO.

The exhibit of the Cloisonné Glass Co., of 66, Berners Street, Oxford Street, W., at Stand No. 63a, Row C, is one of the most artistic in the Hall. This new method of treatment adapts itself in a most wonderful way to all kinds of artistic treatment, giving a good opaque appearance, yet glittering and scintillating like the beautiful old stained-glass. Although the work is opaque, the light is not materially stopped. The method of obtaining this effect is by bending wire of various colours on a sheet of glass into cloisons, so as to form patterns, and filling these former up with powdered glass or beads of glass of various colours. The powdered, or beads of, glass are then fixed to the under sheet of glass by a solution which resists heat and moisture, and another sheet of glass is placed over to protect from dust. The treatment is one which can very well be substituted for leaded glass, so beloved by the architect for avoiding the ugliness of the large glass pane. Cloisonne glass has this advantage over leaded, that it can be cleaned easily, and has no leads on the surface to catch the dust. As evidence of the appreciation this glass is meeting with, the new royal yacht is to be fitted with a number of specially designed windows.

NON-FLAMMABLE WOOD AND FABRICS CO., LTD.

This firm, whose address is Townmead Road, Fulham, S.W., has its stand in the Fire Prevention Section, No. 33. "Non-flammable" wood is now well known and largely used, but the non-flammable fabrics are a somewhat new application of the method of treatment employed by this company. We have tested both wood and fabrics, and found not the slightest trace of flame. The advantages of such a method need no enlarging upon, and judging from the exhaustive official tests that have been carried out upon these materials, they should obtain a still larger vogue than they have at present, which is saying much. A new use to which the wood is being put is in building bungalows and half-timber and concrete villas, which will thus pass the requirements of the by-laws. For fireproof floors, furniture, partitions, ceilings, &c., the wood is highly estimable, and the fire insurance companies recognise its value in giving special terms where used.

WILLIAM MILLAR.

Mr. William Millar, the author of "Plastering, Plain and Decorative," is exhibiting his "Ornato" at Messrs. Potter & Co.'s stand in the Fire Prevention Section, Nos. 27 & 28, in connection with Potter's fireproof floor, being used as a decorative ceiling. "Ornato" is produced from a waste product, to which is added vegetable wool and fibre fabric, the whole forming a hard, tough, yet light substance of a fire-resisting and sanitary nature. It will reproduce the highest relief with all the fine details and undercut of carved wood and chased metal. It is readily fixed to any surface. No skilled labour is required for fixing, and it can be made in any desired size or form. Sign-boards made of this material are also shown in Messrs. Fred Jones & Co.'s stands in Row D, No. 86, and the Fire Prevention Section, No. 12; at the stand of Ripolen, Ltd., in Bay 3, and at the stand of the Asbestos and Asbestic Co., Ltd., in the Fire Prevention Section. Samples of Mr. Millar's modelled stucco and sgraffito are shown at Joseph Arnold's stand, in Row F, No. 124.

THE BUILDERS' JOURNAL.

As usual, the BUILDERS' JOURNAL AND ARCHITECTURAL RECORD occupies a stand at this Exhibition (No. 81, Row C). Here are displayed copies of our own periodical, and also of that finely-illustrated magazine "The Architectural Review," which is also published at these offices. "Specification," which is so highly esteemed by all architects, builders and engineers, is also exhibited. Our representatives will be happy to supply advertisers and readers with all information respecting the publications named.

C. D. MONNINGER.

Saw-sharpening machinery is the special feature of the exhibit of Mr. C. D. Monninger, St. Anna Saw and File Works, 124 and 126, Clerkenwell Road, London, E.C. The improved latest pattern "Climax" band-saw sharpening and setting machine is to be seen at work at his stand (No. 114, Row E). The improved saw-sharpening machine for circular saws and mill webs is also shown working. Much prominence is given to guards for dangerous machinery, the Couzens' patent automatic saw guard being shown fitted to Monninger's improved rising and falling top saw-bench. Another exhibit at this stall is the patent "Practical" moulding machine guard fitted on a latest pattern vertical-spindle moulding machine.

WATERPROOF CEMENT CO.

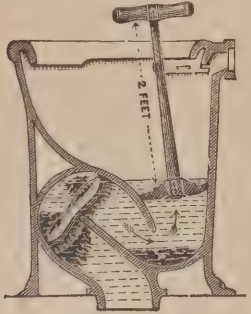
Waterproof cement is a material as yet imperfectly known on the English market. It is exhibited at the stand (No. 137, Row F) of the Waterproof Cement Company, who have works at Brentford and offices at 6, Millbank Street, Westminster, S.W. Portland cement mixed with this composition becomes impermeable to water. The material is used under ordinary conditions, no heat being required for mixing. It takes paint readily, and can, if desired, be faced with ordinary Portland cement. Samples will be forwarded on application, and the company will be pleased if these be submitted to any practical tests that may suggest themselves.

Samples are also exhibited on this stand of the "Standard" damp-proof composition. With a lining of this material properly applied, a guarantee is given that no house or place will show evidence of damp. It is applied in a molten state, and sets quickly. Its price is £5 5s. per ton, free on rail, lesser quantities at 6s. 6d. per cwt.

GEORGE PRICE, LTD.

The "Twentieth Century" bent steel side-locking safe is to be seen at the stand (No. 16 in the Fire Prevention Section) of Messrs. George Price, Ltd., of Wolverhampton. The outer shell is bent cold by powerful hydraulic machinery out of a single steel plate, from ¼in. to ½in. thick, so that the corners are solid and jointless. Doors are of ⅝in. to 1in. solid steel, and are secured at the back by a continuous bar, which, when the door is closed, passes behind the solid web of the T-section door frame. The safe is locked automatically without applying the key to the lock. The "Twentieth Century" strong-room door can also be inspected at this stand. The firm has been established for more than fifty years, and has supplied safes to H.M. Board of Works, War Office, Admiralty, Bank of England, foreign Governments, and numerous large companies.

A. T. COOPER.



Mr. A. T. Cooper, of 92, Moray Road, Finsbury Park, London, N.W., is the inventor and patentee of the patent suction and vacuum pump illustrated herewith. The London School Board have 100 of these drain clearers in use, while the Commissioners of H.M. Prisons have provided the whole of their prisons with them. The exhibit at this stand (No. 32, Row A) also includes Cooper & Bryant's patent "Clincher Lock of the Future."

MELDRUM BROTHERS, LTD.

The exhibits of Messrs. Meldrum Brothers, Limited, of Atlantic Works, City Road, Manchester, will be found at Stand No. 109, Row E. The specialities exhibited are the "Meldrum" forced draught furnace, the "Koker" stoker combined with forced draught, and a model of Meldrum's patent refuse destructor. The "Meldrum" forced draught furnace is suitable for all types of steam boilers. The "Koker" stoker combined with forced draught is adapted for mechanical feeding on the coking principle, and the combination gives results claimed to be in advance of any other mechanical stoker, especially as regards high boiler duty, fuel efficiency, and smokelessness. Refuse destructors are now being erected by this firm for numerous cities and towns in England and Scotland, besides which there are a good number already at work. The temperatures maintained in the Meldrum's destructors ensure the thorough cremation of the fumes, &c., while the higher steaming power from the refuse can be used for electric lighting, sewage pumping, or other useful municipal purpose.

THE STONEHOUSE WORKS CO.

The Stonehouse Works Company (Stand No. 154, Wall Space) is the engineering business of Mr. Edward Tailby, timber merchant and general woodware manufacturer, of 76, Summer Row, Birmingham. Several saw benches are to be seen at this stand. The improved patent high-speed saw bench arranged for cutting and ripping deals and battens is exhibited: its patent radial arm (which can be fitted to any existing make of saw bench) enables work to be executed with very great rapidity. The machine is also provided with a patent pressure attachment and saw guard. In the patent self-acting cross-cut saw bench the wood is placed on the table against the fence, and the stop set at the length required, and by the simple movement of the lever the saw travels, cross-cuts, and returns to its position in four seconds, thus enabling a deal about 14ft. long to be cross-cut into six pieces in less than half a minute. Other saw benches and machines are also to be seen at this stand.

WALTER J. PEARCE, LTD.

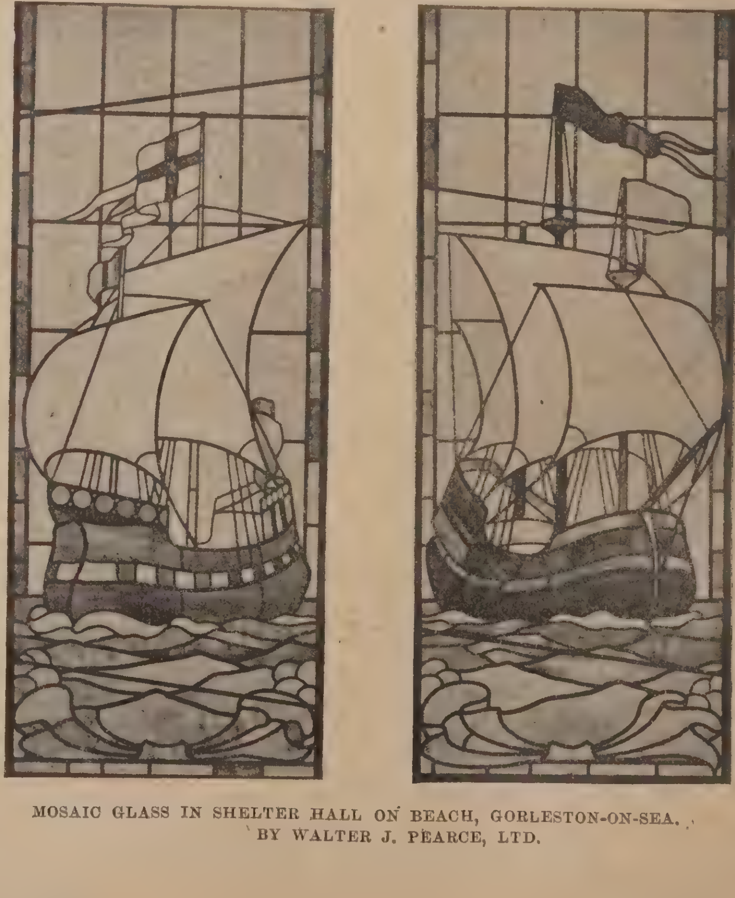
One of the most attractive stands in the Exhibition is that of Messrs. Walter J. Pearce, Ltd., of 41, Gartside Street, and Hardman Street, Deansgate, Manchester. It occupies Special Position No. 1, Row A, and is in the form of a truncated pyramid or Greek pylon, 20ft. high, the wood framing being stained a dull green colour, and the spaces filled with very pleasing specimens of stained-glass work. Mr. Pearce, who is an expert draughtsman, and executes his own designs, makes a speciality of the purely conventional treatment of lead and glass. He is an authority on decoration, and the author of "Painting and Decorating," which is the recognised text-book of the City and Guilds Institute for decorative students. As a colourist he is very skilful. The work shown at this stand includes specimens of glass now being fixed at the new municipal technical school at Manchester, the largest building of its kind in the country; here 15,000ft. of ornamental leaded lights are being used. Other specimens shown are the ceiling lights for the new police courts at Halifax, glass to be placed in several churches, and panels as being used in numerous large mansions in Lancashire, Cheshire, Yorkshire, Leicestershire, on the Thames, and other places. Mr. Pearce's style is distinctly modern and the outcome of a close study of the best method of using lead and glass together. We illustrate two of the designs above.

W. & C. JOHNSON.

Stand No. 87, Row D, is occupied by Messrs. W. & C. Johnson, mahogany and timber merchants, of 118, Hoxton Street, N.E. A stock of mahogany boards is kept, varying from 8in. wide to 24in. wide, the latter being generally needed for counter tops and facias. They are now importing large quantities of Honduras and Nicaragua mahogany in dry boards, square edged, of prime quality. Of other woods, American oak can be had in any size, and at docks and mills the firm have a good selection of logs of American black walnut from 15in. to 30in. wide, which can be sawn to customers' requirements, and also a stock of boards and planks in this wood. American white wood is being more extensively used every year for joinery. It is mild in texture and easily worked, and is imported in square-edged boards and planks fit for immediate use. Teak, birch, Kauri and other pines, Sequoia, and other woods can also be supplied in any quantity by Messrs. Johnson.

SHANKS & CO., LTD.

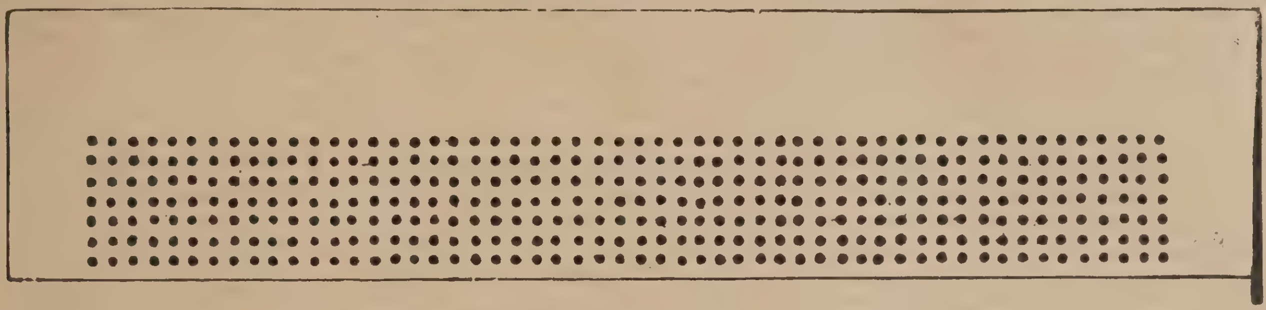
Messrs. Shanks & Co., Ltd., 81, New Bond Street, W., always have an attractive exhibit at the Building Trades' Exhibition, and that now shown at Bay No. 1 is certainly as good as those of any former years. Perhaps the chief exhibit is a handsome needle-spray-bath, which fits *inside* the rim, and cannot therefore harbour dust in any way, as all parts of it can be readily cleansed. It has a top shower and is fitted with all the latest conveniences. "The Perfecto," "Modern," "Fin-de-Siècle," and "Times" baths are also shown. These are excellently finished, the "Perfecto" having a syphonic overflow. One has only to look at an exhibit of this kind to appreciate the great improvement which has been effected in the matter of baths and bathroom fittings, the ingenious taps and outlets provided, and the handsome way in which all enamel work is finished; everything looks so perfectly clean and sanitary, which is of course greatly to be desired in all articles appurtenant to the bath. Messrs. Shanks also exhibit solid porcelain baths, patent new fireclay lavatories, closets, urinals, and sinks, all possessing the same high-class finish. The firm has already so good a reputation as to ensure every visitor to the Exhibition paying special attention to this stand.



MOSAIC GLASS IN SHELTER HALL ON BEACH, GORLESTON-ON-SEA. BY WALTER J. PEARCE, LTD.

B. WARD & CO., LTD.

Messrs. B. Ward & Co., Ltd., of 38 and 39, Parliament Street, S.W. (who exhibit at Stand No. 113, Row E), are concrete specialists and the sole proprietors of Charteris & Longley's patent system of laying wood-block floors. Specimens of this flooring in different woods—in Kauri pine, oak, walnut, teak, jarrah, maple and pitch-pine—are exhibited: one excellent specimen being executed in pitch-pine with a border of oak between thin lines of jarrah. A speciality exhibited at this stand is Ward's artificial stone-leaded stair treads, as being used in Mr. Bentley's new cathedral at Westminster. These treads are very pleasing in appearance, and very effective in giving a good foothold. In constructing these steps a lead grid is laid near the nosing, and the material is then built up around it till level with the tops of the dots which extend in seven rows across the tread; when set, all is rubbed down to a smooth surface. The lead cannot work out, and is pleasant to walk upon. Messrs. Ward & Co. deal very largely in artificial stone mantels, cornice strings, window heads, &c., and have executed work in various large buildings throughout the country. They have also laid a great amount of marble mosaic, tile work and cement flooring. Mr. Norman Shaw was greatly pleased with the manner in which they executed the principal stairs at New Scotland Yard.



WARD'S PATENT STONE-LEADED STAIR TREAD : PLAN SHOWING LEAD DOTS.

FLEMING, BIRKBY & GOODALL, LIMITED.

The "Teon" belting made by Messrs. Fleming, Birkby & Goodall, Limited, of Halifax, may be examined at their stand. This belting has been put to several tests, and has proved itself a good article. It is a most suitable belt for trying positions, or in countries where adverse and extreme climatic influences prevail, "Teon" being absolutely unaffected by the rays of the hottest sun, the most humid or steamy atmosphere, or the keenest frost, no matter how constant or interchangeable any of these conditions may be. Tests prove the ability of the belt to resist the action of dry heat up to 230 degs. Fahr., steam up to 200 degs. Fahr., damp, water and open air exposure; also oil, grease, alkalies and acids (with the exception in the last-named of bi-sulphide of carbon and chloride of sulphur). The basis of "Teon" is a specially-woven fabric, made up without joint or seam, thus securing perfect uniformity and evenness of driving. This cloth is built up in piles, then cemented together under enormous pressure. The cement is a secret preparation, and is the prime factor in enabling the belt to resist influences potentially deleterious in their nature. No ingredient used in this cement is influenced by any heat under 230 degs. Fahr.; and even at a higher temperature the cement is equally efficacious in its adhering power, and the "life" of the belt is in no way impaired. Every belt is moreover passed through a specially-devised stretching apparatus, so that practically all "stretch" is taken out, and the total result is a sound, reliable, and high-grade belt.

THE TERRA-COTTA HOME ARTS.

In the Gallery, Bay No. 27, will be found examples of work in terra-cotta, made under the direction of Mrs. G. F. Watts, at Compton, Surrey, by the village children. We cannot commend too highly the lovely effect obtained by the use of natural clays by those who take a pleasure in their work—the true principle for all art work. To compare this work with the ordinary commercial terra-cotta would be absurd. The sun dials and garden vases are all from designs by Mrs. Watts, whose powers as a highly gifted designer are so well known. We understand that the small village chapel at Compton, carried out under the direction of Mr. G. F. Watts, R.A., and his wife, in this terra-cotta work, is now practically completed, and forms a wonderfully interesting work. At the stand is also shown a pair of small wrought-iron gates for this chapel, made from Mrs. Watts's design by the village blacksmith, unskilled to ornamental metal work, and this fact, while adding to the interest, by the want of finish undoubtedly detracts from the beauty of its design.

THE BRITISH COMPOBOARD CO.

A most interesting exhibit will be found at a stand in Bay No. 10. "Compoboard" is made of wooden slats 4ft. long and 1in. wide joined in an endless web, so that the 4ft. length of the slat forms the width of the complete board. Therefore, in a long board, say 4ft. by 9ft., the end grain of the wood is on the longer edge; in small pieces the end-grain edge is readily detected by the fact that it shows the joining of the slats inch by inch. The board should always be joined on the end-grain edge, with as tight a joint as possible. "Compoboard" will not shrink or swell, except very slightly on the loose edge, and when the joints are stopped can be painted, papered or distempered. It is made 4ft. wide, and in all lengths at 1ft. intervals up to 18ft. "Compoboard" is cheaper, and quicker to put up and cover, than lath and plaster, and avoids all the trouble experienced in using plastering, and needs no waiting for drying weather. It can be understood how great an advantage this material is in allowing of paint, stain, graining, distemper or paper being put on immediately after fixing, and with "compoboard" ceilings there is no cracking or falling down. It can be nailed or screwed, and cut with an ordinary hand-saw. At the stand will be found examples of the use of "compoboard"; the panels formed by covering the joints with mouldings are most pleasing. In the gallery will be found an office made of this material, fitted between wood-framing in imitation of half-timbering, of a very pleasing nature. The address of the British Compobaard Co. is 18, Roscoe Street, Golden Lane, E.C.

MARK FAWCETT & CO.

Stand No. 167, Wall Space, is occupied by Messrs. Mark Fawcett & Co., of 50, Queen Anne's Gate, Westminster, S.W. The "Fawcett" fireproof floor is so well known that there is no need for us to describe it at any length now; suffice to say that it consists, briefly, in the employment of hollow earthenware lintels (which provide air-space both longitudinally and transversely) fitting between the joists and having a dovetail key for the plaster of the ceiling below; the whole of the upper portion being filled in with concrete. The lintels are so shaped that allowance is made for the expansion of the joists, and the ventilation is very thoroughly effected. The floor is thoroughly fireproof, sanitary, light, strong, cheap, and easily constructed. It was fully described and illustrated in our issue for June 7th, 1899. Fawcett floors have been largely adopted by the Government and by the leading architects, both in this country and abroad. Another speciality to be seen at this stand is the "Fawcett" system of wood-block flooring. It is hardly necessary to emphasise the necessity for a floor to be perfectly even, and for it to remain so. In the "Fawcett" system this is accomplished by holding the blocks together by means of a steel tongue $\frac{3}{4}$in. wide and $\frac{1}{16}$in. thick, which fits in grooves cut in the sides of the blocks. It is true that the system is only applicable to the herring-bone pattern, but Messrs. Fawcett find this little drawback, as they have ascertained that 90 per cent. of wood-block floors are laid according to this pattern, and they do not mind leaving the remaining 10 per cent. of work in varied patterns to be executed by those whose systems allow this. Special attention should be called to the fact that the firm specify exactly what quality finish will be given in each case, a most important matter. For instance, their first-quality deal and pitch-pine blocks are *entirely* free from knots on face, and the wood is cut-rift grain; while the second quality is free from shakes, blue sap or knots larger than a halfpenny on face. With a guarantee of this kind one knows exactly what will be obtained, and not find that blocks vaguely described as of "best quality" are full of shakes and knots.

PILKINGTON BROTHERS, LTD.

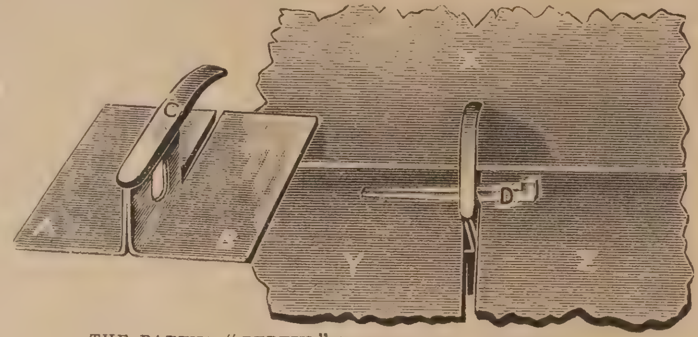
Messrs. Pilkington Brothers, Ltd., of 10, Upper Thames Street, E.C., exhibit their patent wired rolled glass at Stand No. 10 in the Fire Prevention Section. This glass has now been before the public in this country for about three years, and is being increasingly used. One great advantage is that, while in the case of a fire in a building glazed with wired rolled glass the fire can be seen, it is kept confined where it breaks out until the usual extinguishing appliances can be brought to bear on it. This glass is rolled plate glass, in the centre of which wire netting of about 1in. mesh is embedded; and the wire, being thus hermetically sealed up, cannot rust. The wire and glass combine so effectually that if the glass be broken the pieces do not fall out, but the surface remains practically intact, and in the case of fire offers the same resistance to its passage as before. In a recent instance in which it was severely tested, the glass in a skylight bulged inwards by the heat held the water poured upon it until the water boiled away, showing conclusively that the glass, though cracked and stretched, maintained a watertight surface. Fixed in a suitable non-combustible frame, it is an effectual barrier to the passage of fire.

NEWTON CHAMBERS & CO., LTD.

In Wall Space, No. 149, will be found the exhibit of Messrs. Newton Chambers & Co., Ltd., of Thorncliffe Iron Works, near Sheffield, and 16, Great George Street, Westminster, S.W., who are showing their "Thorncliffe Acme of Perfection" cooking apparatus, a patent close and open fire cookery range, having four ovens, all of which can be removed for examination or repair of flues without disturbing the fronts; each oven may be worked independently of the others, and all are perfectly under control. It is also fitted with a boiler for the supply of steam to cooking pans and a vegetable cooker, and could be supplied with a boiler for bath circulation. There are also shown the "Leamington" close and open fire cooking range with tiled coverings, slag-wool lined doors, and lifting bottom grate; the "Yorkshire" improved close and open fire cooking range with high and low oven and circulating boiler; a new independent grill stove, with cast-iron moulded front, inlaid with tiles, tiled panels at ends, and sheet-iron hot closet over grill; a steam closet for standing against wall with copper dishes and covers, Bain Marie, bottom shelf hollow for steam, fitted steam connections, and for condensation; steam vegetable cooker, with three compartments; and the "Thorncliffe" range, "No. 220, S.B.," fitted with oven heated by gas at the bottom, and oven for coal fire at the top, with hot plate. At this stand are also steam pans, stable fittings, garden rollers, radiators, independent cooking stoves, garden furniture, &c.

PRYKE & PALMER.

Messrs. Pryke & Palmer, whose offices are at 47 and 48, Upper Thames Street, E.C., have their stand in Row F, No. 123; and among a number of interesting exhibits shown, there is the patent "Perfik" roof-slate fastener shown by the accompanying illustration. For repairs to slate roofs, this is intended to supersede the old-fashioned lead or zinc strips. Its particular advantages are that one fastener binds three slates, that it will not shift by wind or sliding snow, holds the bottom edge of slate down, is scarcely perceptible on a roof, and will not catch or tear workmen's clothes. In fixing the fastener, the damaged slate is first removed, and replaced with a new one, as at X in illustration. The flanges A B of strap are shipped under the old slates Y Z, the part C standing up between. The strap is then pushed upwards until the notch in part C retains the bottom edge of the new slate X. The wedge D is inserted into the hole in fastener, and driven until sufficiently wedged to secure the slate from slipping. Another novelty shown is Fullerton's patent metallic connections for w.c. pans, in lead or brass, with short or long arm connectors.



THE PATENT "PERFIK" ROOF-SLATE FASTENER.

EWART & SON, LTD.

Messrs. Ewart & Son, Ltd., of 346, 348, and 350, Euston Road, London, show at their stand Nos. 20, 21, and 22, Row A, the "Lightning" geyser, for supplying hot water, in seven sizes; the "Champion" geyser, in five sizes, for positions where no head of water is to be had; the "Surprise" geyser, in four sizes and two patterns, for positions where good water pressure can be had; the "Califont" for delivering hot water to all parts of the house; the "Acme" geyser, with Bunsen burner; the "Success" geyser for oil; the "Royal" geyser, which is very cheap and rapid in action; and the "National" geyser. The firm also show their "Agate" porcelain enamel baths, and a novel and useful device, a bath seat, made to suspend from the sides of the bath by wire hooks. Various other bath-room fittings are shown.

M. T. MEDWAY.

Mr. M. T. Medway, the well-known lift, hoist and crane manufacturer, of Albert Works, Rolt Street, Deptford, S.E., shows at his stand, No. 56, Row B, a hand-power self-sustaining dinner lift, and an electric lift, both in working order. The self-sustaining action for any weight is a very important advantage in connection with Mr. Medway's lifts, and, in connection with his hydraulic lifts, the patent hydraulic starting valves should be especially taken note of.

THE GLENFIELD PREMIER BRICK AND TERRA-COTTA CO., LTD.

This firm, whose address is Glenfield, near Leicester, on its stand in Row F, No. 130, show samples of red bricks, hand-pressed facing bricks, tapped wire-cuts for seconds facing and moulded and ornamental bricks of all kinds. Terra-cotta chimney pots, ridge tiles and finials are also shown made of a special clay which allows of these articles being turned out very true, not warped as too often happens with terra-cotta, and is such a very great defect. Yet, notwithstanding the trueness, the terra-cotta has been well burnt and not "biscuited" to avoid the warping under high temperatures.

THE DELTA METAL CO., LTD.

The malleable bronze alloys manufactured by the Delta Metal Co., Ltd., of 110, Cannon Street, E.C., which has its stand at No. 53, Row B, more particularly "Delta metal No. I. and No. IV.," possess not only very great strength and toughness, but also a remarkably high resistance to corrosion. In all cases where iron and steel are unsuitable owing to their rapid deterioration, and where the use of gunmetal and bronze cannot be allowed on account of insufficient strength, "Delta" alloys will be found most reliable, durable and economical. "Delta metal Nos. I. and IV." can be forged at a dull red heat, and are most useful as materials for repairs. The specialities shown at this stand are angles, tees, joists and special-shaped section bars for use in the construction of window frames, casements, &c., and "Dick's patent extended stair treads, nosings and carpet plates" in "Delta metal," brass, &c.; these latter have a corrugated surface to give a good foothold.

FIREPROOF PARTITION SYNDICATE, LTD.

The Fireproof Partition Syndicate, Limited, of 10, York Buildings, Adelphi, W.C., exhibit at Row B, Stand 48, a two-roomed "week-end" bungalow composed of their patent dovetail corrugated metal-sheeting, while a gate-keeper's office is exhibited in the fire-proofing section. The sheets are formed by patent machinery into dovetail grooves, which form an excellent double key for any kind of plastic material, thus rendering them solid, fire-, sound-, damp-, and vermin-proof walls only 2in. thick. The sheet being without perforations, there is no waste of plaster, or any fear in case of fire of flames passing through after the plaster has fallen away from intense heat. The roofs of the buildings shown are also made with the patent sheeting, plastered, with tiles embedded. The saving in space in a building where these partitions are used means a nett gain of 4in. on each partition. One partition saves 4in.; two, 8in.; three, 12in.: thus, with three partitions, saving 1 cubic foot through the entire building, as the 2in. partitions are equal in strength to a studding partition 6in. thick. The firm also show samples of patent fireproof floors, constructed on a similar principle. They can be both cheaply and speedily erected, and can be plastered immediately if required, while it is claimed that the weight per foot super. is considerably less than that of any other fireproof floor on the market to-day.

J. OATES.

The exhibit at Stand 31, Row A, consists of a number of "Empire" patent wallpaper trimming machines made by Mr. J. Oates, of 24 George Street, Huddersfield. These are shown in operation, edging all kinds of wallpapers, from common pulps, grounds, and sanitaries, &c., up to Anaglypta; and that so expeditiously and a the same time so accurately, that visitors cannot help being struck with the great difference between the results obtained by the use of this neat little labour-saving machine and the old-fashioned, slow, and tedious method of work with hand scissors; indeed, the latter method must finally become a thing of the past, as an ever-increasing number of these wallpaper trimmers are being used throughout the Kingdom and abroad. The 1901 model shown at this stand embodies the very latest improvements in trimming machines.

MOFFATT & EASTMEAD, LTD.

Moffatt & Eastmead, Ltd., lift manufacturers, of 39, Victoria Street, S.W., occupy Bay No. 5. Here may be seen an electrically-driven warehouse lift, a patent self-sustaining hand-power goods and dinner lifts, a belt-driven dispatch sack hoist for granaries, breweries, stores, barrow hoisting, &c., and a self-sustaining hoisting crab which dispenses with both brake and ratchet, and will not allow the handle to fly back. The warehouse lift and sack hoist are shown working, and are driven by a 3-h.p. electric motor supplied by the General Electric Company, Limited. Another exhibit is one of Moffatt's improved 1900 patent feed-water heaters and fuel economisers for steam boilers.

In designing their hydraulic lifts Messrs. Moffatt & Eastmead's main object has been to secure safety and economy. The former has been attained from results gained in actual practice, and the latter by reducing the number of parts to a minimum, retaining only those necessary to efficient working.

L. LEWIS & Co.

Messrs. L. Lewis & Co., of 51, Shirland Road, Paddington, W., are the manufacturers of the flexible damp-course, patent mastic roofing felt and slaters' felt to be seen at Stand No. 17, Row A. The damp-course is manufactured by a chemical process, and is not liable to crack or ooze out under pressure. It is manufactured in lengths of 33ft. (widths to order), thus having an advantage over 32in. slabs and saving from 25 to 30 per cent. in material and labour. The flexible mastic roofing felt is manufactured on the same principle as the damp-course. Messrs. Lewis claim that this felt is much superior to the ordinary straw or fibrous felt, both in strength and durability. The mastic slaters' felt is manufactured on the same principle as the roofing felt, but is thinner in substance. The price of the mastic damp-course, extra quality, 9in. wide, is 4d. per lineal yd. in rolls of 11yds. The roofing felt costs 5s. 6d. per roll of 11yds. by 39½in. wide (contents about 108ft. super.). The slaters' felt, 11 or 22yds. long, 39½in. wide, costs 3s. and 6s. respectively (contents of rolls about 108 and 216 super. ft.). These goods have been supplied to the War Office, Admiralty, General Post Office and other Government offices.

T. FEWSTER WILKINSON.

Mr. T. Fewster Wilkinson feels that as the present form of stairs has been in universal use since very ancient times (possibly since the Pyramids of Egypt were built) there will be a good deal of inherited prejudice to overcome in the adoption of his own patent stairs. These are designed to combine easier risers with wider treads than can be arranged on the ordinary system, and instead of being level across the whole width of the stairs the treads alternate to the right and left. Handrails at each side guide the person in the centre of the staircase, and he places his left foot on the left-hand steps. Mr. Wilkinson's address is Bartle Garth, Reepham-by-Lincoln, and his stand No. 29, Row A.

JULIUS HÜLSEN & CO.

Messrs. Julius Hülsen & Co., of Newcastle-on-Tyne, in their exhibit, demonstrate the efficiency of their precipitated carbonate of barytes as a preventative against scum and discolouration in facing bricks, terra-cotta, ridges, quarries, &c. Specimens are shown from the same seam of clay, partly with and partly without an admixture of the carbonate of barytes. Those made without the barytes are scummed, whilst those with which the barytes has been mixed are quite clean and of a good colour. "Linkum" Patent Belting is also exhibited at this stall. This is a belting made up of links punched from manufactured sheets of specially-prepared and highly-compressed fibre. Being made in this way, every link is as strong as its fellow; and as it is claimed that a "Linkum" link is of considerably greater tensile strength than the best leather link of the same section, the belt is very serviceable.

STANLEY BROTHERS, LIMITED.

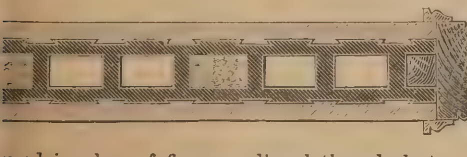
Messrs. Stanley Brothers, Limited, of Nuneaton, have the following exhibits on their stand:—White and coloured enamelled bricks; improved salt and grey granite bricks, for Board schools, hospitals and public buildings; red and buff chimney pots; brown and glazed cane sinks; ornamental red and buff terra-cotta; glazed socket pipes and connections; semi-encaustic paving tiles; blue pressed bricks, garden tiles, &c.; red ridge tiles, finials, ventilating bricks, &c.; red and buff terra-cotta and glazed vases; roofing tiles, malt kiln tiles; Staffordshire quarries, ridges, &c. This firm has branch works at Burslem and Willenhall, near Coventry, and collieries at Nuneaton and Bedworth.

JOHN P. WHITE.

As a maker of beautiful mantelpieces and garden furniture Mr. John P. White, of the Phyghtle Works, Bedford, occupies a prominent place in this country. The exhibits at his stand (No. 68, Row C) are fine specimens of design and workmanship. It is sufficient to mention that he has work from the hands of such men as Mr. H. Wilson, Mr. C. H. Quinnell, Mr. G. M. Elwood, to draw attention to his exhibit. A mantel by Mr. Wilson is to be seen at this stand. It is in oak with coromandel inlay. Mr. White's garden seats and gates have none of that foolish gewgaw which passes under the name of "ornament," but show a quiet restraint in design which is most desirable for all articles associated with a garden. The "Phyghtle" garden seat (by Mr. Quinnell) is particularly happy in treatment. In his new catalogue of garden furniture, Mr. White says: "The good results produced by my garden seat and gate catalogues, and the recent development in the craft of gradening, have suggested to me that there must be many gentlemen—members of the architectural profession and others—who are anxious to obtain some modern representations of the various quaint conceits and devices which contribute so much to the charm of the Old English Garden." And in this, with the assistance of Messrs. Forsyth & Maule, Mr. Quinnell, and Mr. James S. Cooper, architects, Mr. White has certainly succeeded. We would call special attention to the manner in which these catalogues are produced; they are well printed on good paper, and are illustrated by line drawings of very considerable merit. Roberts' drawing-board rest, fixed by four screws, is also to be seen at this stand.

SHEPWOOD & COMPANY.

The "Shepwood" patent partition brick, made by Messrs. Shepwood & Company, of Lindisfarne, Walton-on-Thames, can be inspected in the Fire Prevention Section of the Exhibition. It has hollow spaces passing vertically through it, so arranged that when the bricks are placed over one another with bonded joints the spaces are continuous. It is claimed that a partition constructed with these bricks, finishing 2½in. thick, is as rigid as an ordinary 4½in. wall; it will support itself across a wide span, and may be used in place of fire-spreading lath-and-plaster partitions, and for closet and lavatory divisions, articles and dormitory partitions, where space is valuable. The size of the bricks is 13½in. by 6in. by 1⅞in. thick. No ironwork is used in construction. These bricks have been used in numerous important buildings, such as the North-Eastern, St. George's, and St. Thomas's Hospitals; the Stock Exchange; Bank of Scotland, Bishopsgate Street; Victoria Theatre, Manchester; and Pitman Schools, Southampton Row.



S. T. CLOTHIER.

Mr. S. T. Clothier, quarry owner and stone merchant, of Street, Somerset, exhibits at Stand No. 34, Row A, flags, steps, and kerbs of Keinton stone, a very fine-grained blue-greystone. Flags and kerbs of this stone are very suitable for public footpaths, and are in use throughout the Midlands and South of England for this purpose. The rubbed flags for paving public buildings of all kinds have been used in the Royal Courts of Justice, Strand; and for tennis and racquet courts at Princes' Club, Knightsbridge, the University Club, Cambridge, Sir A. Noble's, &c. Their price is 1s. per ft. cube at the quarries, which are at Keinton, Somerton, and Street, in Somersetshire.

Blue and grey blocks are also shown of forest stone, a fine grained blue and grey sandstone, suitable for steps, landings, monumental and general architectural purposes, in general use throughout the Midlands and South of England. The price of this stone is 2s. per ft. cube at the quarries, which are at Knockley, Darkhill and Gosty Knoll, Forest of Dean, Gloucestershire.

HOULDSWORTH'S PATENT BARROW COMPANY.

The exhibits of Messrs. Houldsworth's Patent Barrow Company, of Park Lane, Keighley, at their stand in a Gallery bay, consist of barrows and barrow fittings. One of the great faults in ordinary barrow wheels is the constant repair necessitated by the failure of the axles. In Houldsworth's patent wheel it is claimed that this is entirely obviated by making the axle of the wheel really of two-flanged axles of steel bolted through the stays, which are of wood, and form a cushion to the axle. As the axles work in patent Bush bearings, the liability to get out of order is reduced to a minimum. The wheel is stated to always run true and to outlast several of the usual make. The Bush bearings referred to are driven in with a hammer into the usual hole bored in the axle block. Barrows can be fitted with patent adjustable bearings if required.

H. C. SLINGSBY.

The patent trucks made by H. C. Slingsby, of 142, 144, 146, Old Street, E.C., where there are 20,000 sq. ft. of show-rooms, are too well known to need much description. They are obtainable in various sizes for all trades, run both ways, spin like a top, and have a sliding wheel at each end. A number of these trucks are shown—being a selection from 400 styles and sizes listed, and 1,000 styles and sizes to be seen—at 142, 144, 146, Old Street, E.C., which is the new address of the firm. The offices, were formerly at 30, Gray's Inn Road, E.C. Mr. Slingsby's exhibit occupies Wall Space 157.

CROSSLEY BROTHERS, LIMITED.

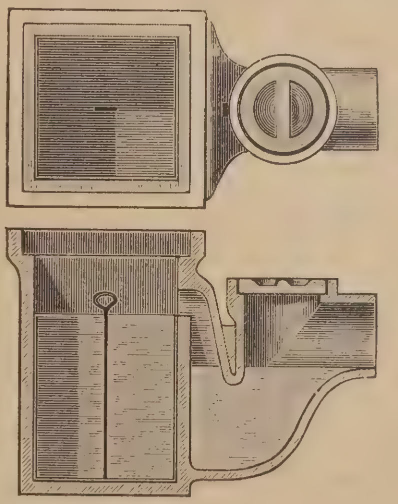
The exhibit of Messrs. Crossley Bros., Limited, of 10, St. Bride Street, E.C., in Wall Space No. 124, consists of the following engines: One type "U" gas engine of the latest pattern, capable of developing 33 effective h.p. as a constant working load. One type "OE" high-speed electric lighting gas engine fitted with one specially heavy fly-wheel, supported by outside bearing. This engine is capable of developing 12½ brake h.p. as a constant working load, and is used for driving a dynamo for lighting this stand. A perfectly steady light can be obtained with this type of engine, without accumulators. One type "JJ" oil engine, capable of developing 1½ brake h.p. as a constant working load. The "U" type above referred to drive the brick-making machinery on the adjacent stand of Messrs. Thomas C. Fawcett, Limited, engineers, of Hunslet Road, Leeds. Also, in addition to the above, there is one of the "M" type gas engines, capable of developing 7 brake h.p. as a constant working load, on Messrs. Pullman and Mann's Stand, Leeds; and an "S" type engine, giving 20 brake h p., on the stand of Messrs. Bradley & Craven, of Wakefield.

H. J. & C. MAJOR, LIMITED.

Majors' patent waterproof roofing tiles are the leading feature of the exhibit of H. J. & C. Major, Limited, of the Patent Tile Works, Bridgwater, at Stand No. 106, Row E. The various patterns of these tiles are well known for their general utility and efficiency, combined with economy. Their adaptability for buildings of every description has been shown by the adoption of them by leading architects, and by the demand for them by landowners, contractors and builders for all kinds of roofing purposes in the United Kingdom, the British Colonies, and foreign countries. The general assortment of ridge tiles, paving bricks, oven bricks, ornamental, and other building bricks deserves special attention, as well as the roofing tiles above referred to. Messrs. H. J. & C. Major, Limited, have been awarded the highest and only award for roofing tiles in every competition in Great Britain and Ireland since 1884, and also the highest and only award for roofing tiles at the Paris Exhibition, 1900.

JOSEPH PLACE & SONS, LIMITED.

The chief exhibits of Messrs. Joseph Place & Sons, Ltd., of Darwen, Lancs. (who occupy Stand No. 135, Row F), are the "Adi" and "Zaza" chimney pots, the patent kiln bottoms, and Place's patent street gulley. The "Adi" and "Zaza" chimney pots are designed to prevent smoky chimneys, by means of having double-arms and louvres, the former with the louvres below the arms and the latter with them above. In the "Adi," when there is a direct down-draught, the wind rushes in at the top and out at the side arms, thus creating a vacuum in the flue. The smoke ascends the flue to fill this vacuum, and is driven out at the side arms. The stronger the wind that falls on the top of the chimney, the better the chimney pot answers. The "Zaza" chimney pot should be used where the wind re-bounds from a high building; as the "Adi" will not in all cases answer under these conditions. The "Zaza" increases the up-draught and prevents a down-draught. The patent chequer bricks for kiln bottoms give increased strength and decreased solid on floor level; rubbish cannot lodge on the supporting walls, nor between the chequers, the supporting walls are tied together and lateral movements are prevented, and a 4-in. pipe can stand anywhere and still have free draught. These kiln bottoms should be seen to be appreciated. The special advantage of the patent street gulley, which is illustrated on this page, is that by the arrangement of the outlet the whole depth of the gulley is utilised for sediment, and still the outlet and gulley are accessible in every part. This distinctly advantageous arrangement is stated to be quite as cheap as the ordinary gulley. Samples of white enamelled and special salt glazed bricks are also shown; these are made from the firm's "diamond" stoneware clay, which enables a brick to be made perfectly true on the bed and still get the same high glaze as other makers.



PLACE'S PATENT STREET GULLEY, NO. 249.

MOORE'S PATENTS COMPANY, LIMITED.

The exhibit of Moore's Patents Company Limited, Nightingale Hall, Lower Edmonton, N., is to be seen at Row C, Stand No. 65. When the sashes of Moore's patent vertical sliding sash windows are at the bottom they are always hinged, and then a person standing inside on the floor can, by moving a handle, turn them inside and paint, repair, or clean the outside, and replace them, as easily as an ordinary door is opened and closed, without steps, poles, risk of accident or detachment. These sashes cannot be opened inwards until they are down and hinged, and when turned inwards for cleaning or full ventilation, they cannot become unhinged, or get wrong when being replaced. When specified of similar material and shape they cost no more to make than ordinary windows.

Both frames in Moore's patent casement windows are exactly the same as in ordinary casements, opening outwards, with solid or nailed-down beadings. By moving a catch on the inside with the finger when the sash is open, the outside will turn inside for cleaning; the sash can be replaced, and the catch pushed back, with great ease and rapidity. When fitted with a non-rattling stay and catch they cost only a trifle more than the ordinary casement. Other exhibits at this stand are: Patent fanlight or skylight openers, two-way door springs and hinges, and one-way door springs. The two-way door springs are screwed on the floor (without cutting a hole for them) and on the bottom of the door, and are almost invisible. They have a screw adjustment to suit them to heavy or light doors, and the wearing part runs in oil.

STANDARD SANITARY MANUFACTURING CO.

The Standard Sanitary Manufacturing Co., who exhibit at Stand No. 82, Row C, have opened London showrooms at 22, Holborn Viaduct. The head office of the firm is at Pittsburg, U.S.A., but they have established branch offices and agencies in all the principal cities of the world, and are now placing on the market high-class porcelain enamelled baths, lavatories, and similar goods. The "Standard" baths were awarded the only Grand Prix at the Paris Exhibition of 1900, and also the gold medal of the Department of Hygiene and Social Economy. The firm control practically every cast-iron enamel bath made in the United States, but none of the plants so controlled produce the bath styled "Standard," which is made only at the works in Allegheny, and under a secret process not granted to the other plants. The following is a specification of an "Elysian" bath: White enamelled bath tub, with 3in. enamelled roll rim; brass common overflow connected with nickel-plated overflow; waste plug with rubber stopper; width, $23\frac{1}{2}$in.; depth, $18\frac{1}{2}$in.; height from floor, 24in.; length over rim, 4ft. 5in.; length inside, 4ft.; price, £7 5s.

Mr. Leon N. Loeb is the general manager for the United Kingdom.

JOHN KNOWLES & CO.

The patent "B.P." safety stopper, to be seen at the stand (No. 83, Row C) of Messrs. John Knowles & Co., of 38, King's Road, N.W., has nothing whatever to do with the gallant defender of Mafeking, the two letters standing for "back-pressure." The "B.P." stopper has a flange and clip with a quarter-turn; and while being easy of access, there is no risk of the stopper being removed. At the same time, for cleansing purposes a quarter-turn is sufficient to unfasten it. Other exhibits of Messrs. John Knowles & Co. are the "Anti-Vap" street gulley (patent), the "Wyvurst" patent improved drainage channels, Light's patent quick flush trap, with narrow channel, and the "Aquarius" wash-down closet.

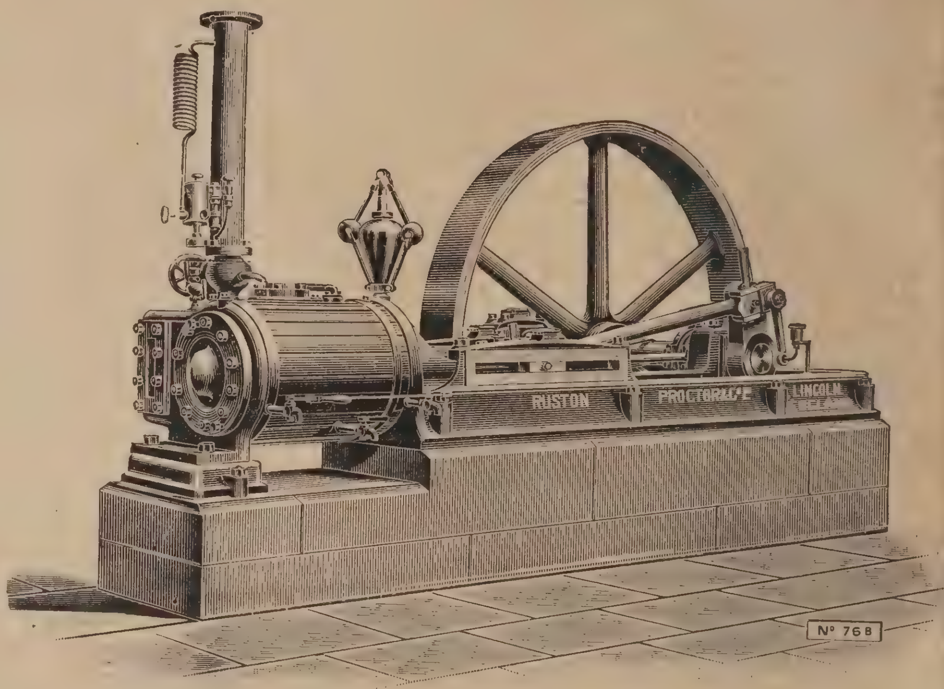
RUSTON, PROCTOR & CO., LTD.

At Stand No. 155, Wall Space, Messrs. Ruston, Proctor & Co., Ltd., of Lincoln, show three types of engines of particular interest to builders and contractors. They are a 14 nominal h.p. double-cylinder portable steam-engine; a 14in. by 28in. longstroke horizontal steam-engine; and a 9 brake h.p. "Ruston" patent horizontal oil engine. The first has all its parts mounted on planed steel seatings or supports, riveted to the boiler, so that no bolts enter the steam space, thus avoiding leaky steam joints and enabling any part to be taken out and replaced with ease. All is of ample strength for 90lbs. working steam-pressure per square inch. This engine was awarded the "Grand Prix" at the Paris Exhibition last year.

The improved longstroke horizontal steam engine made by Messrs. Ruston, Proctor & Co. (illustrated on this page) has automatic expansion gear of the "Stephenson" type, controlled by a very sensitive "spring" governor, and will develop a large amount of power with economy.

The "Ruston" patent horizontal oil engine has several noteworthy features. The consumption of Russian oil is from under $\frac{5}{8}$ pint in the larger sizes to 1 pint per E.H.P. per hour in the smaller sizes. The whole is extremely simple, easily started, and requires practically no attention.

Messrs. Ruston, Proctor & Co., Ltd., also manufacture steam traction engines and road locomotives, steam navvies for excavating, saw benches, mortar grinding mills, winding, hauling and hoisting engines, and all kinds of similar machinery.



IMPROVED LONGSTROKE HORIZONTAL STEAM-ENGINE, BY RUSTON, PROCTOR & CO., LTD.

STANDARDISING SIZE OF BRICKS.

A conference between representatives of the Institute of Civil Engineers, the Royal Institute of British Architects, and representatives of brickmakers, will be held at the Exhibition on Friday next, at 4 p.m., to discuss the question of standardising the size of bricks. The following is the standard suggested by the two Institutions:—

1. The length of the brick should be double the width, plus the thickness of one vertical joint.

2. Brickwork should measure four courses of bricks and four joints to a foot. Joints should be $\frac{1}{4}$in. thick and an extra $\frac{1}{16}$in., making $\frac{5}{16}$in., for the bed joints to cover irregularities in the bricks; this gives a standard length of $9\frac{1}{4}$in. centre to centre of joints The bricks to be measured in the following manner: Eight stretchers laid square end and splay end in contact in a straight line to measure 72in. Eight headers laid side by side frog upwards in a straight line to measure 35in. Eight bricks laid the first brick frog downwards and then alternately frog to frog and back to back to measure 21in. This is to apply to all classes of walling bricks, both machine and hand made and facing bricks. The proposal to arrange a definite standard for the size of bricks is one which should meet with the approval and support of all who are interested in sound brickwork, it being impossible with the varying sizes of bricks as at present made to keep good sectional bond. It is hoped that a resolution will be passed at this conference which will establish a standard as suggested. At the meeting statements will be made as to the standards observed in America and Germany.

Anyone desirous of attending this meeting may obtain admission to the Hall upon application to 43, Essex Street, W.C.

Visits and Meetings during the Exhibition.

Although there was no formal ceremony of the opening of the Building Trades' Exhibition, the opening day was made the occasion of a reception and luncheon to a large deputation of German brickmakers who visited the Exhibition on that day. A number of exhibitors connected with the claymaking industry were invited to meet the deputation, and over 100 sat down to luncheon, under the presidency of Mr. H Greville Montgomery. After the toast of "The King" had been proposed by the Chairman, and duly honoured, the toast of "The Visitors" followed. Mr. Montgomery welcomed the deputation in his own name and in the name of the British Clayworkers, and hoped that their visit to this country would be as pleasan as had that of the British Clayworkers to Germany. These sentiments were conveyed to the guests by Herr Mark, who in returning thanks referred to the great progress that had been made within the last fifty years. It had been his privilege to attend the first great International Exhibition opened by Her late Majesty, and he thought all would agree that in no branch of industry had progress been so marked as in that in the building trades. The present Exhibition was a splendid and instructive one, and he hoped that all those who had exhibited in it would benefit by their enterprise. He asked all the Germans present to drink to the success of the Exhibition and to the host, Mr. Montgomery. This was responded to with musical honours in a hearty manner which astonished the Englishmen present. In responding, Mr Montgomery called upon his friends not to be outdone in lung power, and with the assistance of the band of the Coldstream Guards, which had performed during the luncheon, the Germans were treated to a rendering of "For they are jolly good fellows." The visitors seemed much to appreciate the honour done them, and they were most interested in all the different sections of the Exhibition.

On Thursday the party travelled from London to Sittingbourne, and went over the works of Messrs. Smeed, Dean & Co., Ltd., one of the largest firms of brick manufacturers in this country. The visitors were entertained to luncheon at the Town Hall, under the chairmanship of Mr. Dean, the managing director. This week they are due at Peterborough.

The following are the remaining visits and meetings that will take place during the time the exhibition remains open—till April 27th:—

Wednesday, 24th.—Visit of Institute of Sanitary Engineers.
Thursday, 25th.—Visit of Society of Architects. Annual meeting and dinner of Institute of Clayworkers.
Friday, 26th.—Conference on standardising of bricks, at 4 o'clock.

THE BUILDERS' JOURNAL & ARCHITECTURAL RECORD

May 1, 1901.
No. CCCXXV.

Effingham House,
Arundel Street,
Strand, W.C.

EVERY WEDNESDAY, PRICE 2D.

SCALE OF CHARGES.
For Contract and Official Advertisements.
Competitions, Contracts, all Notices issued by Corporate Bodies, Local and other Boards, Prospectuses of Public Companies, and Trade Paragraph Advertisements : s. d.
Per Line 0 9

Partnerships, Apprenticeships, Land, Businesses, Trade, and General Advertisements, and Sales by Auction :

Effingham House, Arundel Street, Strand, W.C.**

Special attention is directed to the three new insurance schemes which we have instituted. Particulars will be found on page 242 of this issue.

An Architectural Causerie.

The Young Engineer. Mr. Maw is to be congratulated on his excellent presidential address to the Institution of Mechanical Engineers (see page 238 of this issue) and for the clear and capable manner in which he dealt with the problem of educating the young engineer. There can be no doubt that our systems of technical examination are in many respects deficient and in some respects absurd; for instance, a person intending to become an architect or an engineer is obliged to devote a great deal too much time to geography, political history, and similar subjects quite without his sphere. A general knowledge is well and good when kept within bounds, but when its acquisition means the sacrifice of time and energy only too much needed for the study of the special work in view, the system becomes foolish. The adage that one thing at a time is essential to success has no truer application than that of engineering education. To do any good, one must specialise. It is imperative for the engineer to concentrate all his efforts on one branch of his work, and even then he will find that *tempus fugit*, while the acquisition of knowledge is exceeding long. But specialisation must not be adopted too soon, for here is another pitfall. For instance, an electrical engineer who commences to specialise in instrument-making without having had a general experience of workshop practice will find himself greatly hampered and his outlook restricted. We are, however, quite in accord with Mr. Maw's views that specialisation should at least be commenced during the college career rather than subsequently.

A Street View in Granada. The illustration on this page of a street view in Granada is from a sepia drawing by Mr. Francis W. Bedford, who has established so excellent a reputation as a draughtsman. Wherever the Arab and Moor have been there we see the same blaze of colour—in coloured tile or wall, bright-toned roofs, variegated hangings and gilded enrichments. This drawing by Mr. Bedford possesses the great characteristic of *feeling* colour though in black and white. We also *feel* the sunshine, and can imagine ourselves walking down that brilliant street, dazzled by the glare—perhaps stifled with the heat—but certainly charmed with the colour scheme.

Christ's Hospital. Christ's Hospital, off Newgate Street, is so interesting architecturally, and possesses a history so replete with honoured associations, that one anxiously awaits the decision of Parliament in regard to the Bill which, if passed, will enable the Governors (with the consent of the Charity Commissioners) to sell the site, the object being to sweep away all the existing buildings and replace them with shops and warehouses having "all the latest improvements." The Society for the Protection of Ancient Buildings (with Lord Balcarres and Mr. Thackeray Turner at their head), Lord Monkswell, and other influential gentlemen are doing their utmost to prevent this happening, their contention being that there is no necessity for such a demolition. Two years ago the Charity Commissioners sanctioned a scheme for removing the principal school to Horsham (where the new buildings designed by Mr. Aston Webb, A.R.A., are making good progress), but there was nothing then said about pulling down the old buildings. It is averred that unless the site is sold there will not be sufficient funds to conduct the school at Horsham, but it does not seem that the other resources of the foundation have been exhausted, nor—a most important fact—have efforts been made to let the schools for other purposes; in fact, the Commissioners strongly oppose the proposal that the buildings should be adapted to the needs of St. Bartholomew's Hospital close by. "The difficulties which hamper the free treatment of the site appear to be that parts of the site are leasehold, and that a large part has at some period been used for interments. Parliament has declared that it is unlawful to build on a disused burial-ground, and it is sought by the present Bill to override this enactment." Apparently the chief idea of the promoters of the Bill is to get as much money out of the site as they can—it matters not how; and we therefore hope that their project will be defeated and a fine building thus allowed to grace the City for many more years to come.

A STREET IN GRANADA. DRAWN BY FRANCIS W. BEDFORD.

Standardizing Bricks. We are afraid that the conference held at the Royal Agricultural Hall, Islington, on Friday last, did not effect much towards the standardization of bricks, though indirectly it may have been the beginning of what will ultimately result in some standard being adopted. The resolutions of the joint committee of the Royal Institute of British Architects and the Institute of Civil Engineers were laid before the meeting for confirmation, but what actually took place was the pressing of a resolution "that it is desirable to form a committee to consider the propriety of standardizing the size of bricks." As will be seen, however, by the report which we publish on another page, several interesting opinions by representative men were expressed at the conference. Though the views expressed differ so widely, of three things there can be no doubt. First, it is extremely difficult to determine what the shrinkage in a particular brick will be. Secondly, good bricks conforming to the standard will be more costly than those which do not. Thirdly, brickmakers at present experience no difficulty in selling their bricks irrespective of any standard, and therefore, if any change is made, it is for the convenience of architects, engineers and contractors. On the whole, we think the best that can be done will be for the committee that is to be formed to decide on a standard and then leave it; to the brickmakers to do their best to conform to it; but brickmaking is not an exact science and those bricks which will need to be "thrown away" because they are above or below the standard size will doubtless offer considerable hindrance to the proposal being adopted throughout the country.

SOME NORTH CORNWALL CHURCHES.—I.

BY FRANK BAINES.

ARCHITECTURE in England, and especially in the counties of Cornwall and Devon, has taken into indissoluble partnership a second and, one might say, supreme decorative power. Nowhere else is this more apparent than in the West Country—that hot-bed of cliquism and paradise of extreme partisanship, that county of strong English characteristics and plain simplicity of manners.

The predominant partner I speak of is Nature. There can be little doubt of her predominance, for she has written it across almost all the churches in bold strokes of her inimitable hand; and only where the church stands away from her on the extreme cliff edge, facing the rude Atlantic breezes, does she seem to lose her power. Yet even here she sends her army of smaller pioneers, in the shape of mosses that lurk wherever a cranny will give hold, and the multi-coloured lichen which marks every stone her debtor. She holds them in the face of the storm and the bitter flying surges, which fling the shingles high over the rocky headlands. The stinging spray bombards her, but the tamarisk flourishes through it all, and the lichen and all the varied mosaic work tells of her partnership.

Architecture in North Cornwall is not given to grand or striking effects; it is the expression of a people homely, quaint, and very strong, with an original turn given to an old style. Even the style is charged with an individual character in keeping with the country; an odd strangeness marks it as a new creation rather than a model of the "mode." It can never be studied for its light upon the style of its age, but it will, I think, be often studied for itself. This study will amply repay any enthusiast, for it is so intimately connected and linked with the life of its people that a rich harvest can be reaped of legends, ghost stories, parsimonious parsons, and tales of the pirate kings of the coast and their dare-devilry. They are all bound up together, the present, the past, the people and their churches; for though Nonconformity has a great hold on Cornwall, all the legendary life and history belong to the churches.

The bit of coast which runs south from Bude and Boscastle past Tintagel headland, and round the sweeping bays to Trevone, Pentire, and Trevose Head, enclose within a twenty-mile circle a vast amount of interesting architecture. Interesting is the adjective I apply to it in the strict sense, for it is extremely so, a most fascinating county architecture, yet, as I have said before, with no grandeur, no splendid effects, no sublimities. I state its limitations only to enforce its charm, and in no wise to qualify it, for to many the charm of quaintness, of quiet beauty, of green old age, both literally and figuratively, is enough.

The whole countryside abounds in churches, all with some claim to attention, and many possessing great interest both architecturally and archæologically. From a long rolling down which runs landwards from Port Quin the eye can sweep round for miles over undulating luxurious pasture land, with the combes thickly wooded in between. Topping the shoulder of down, the tall spire of St. Minver rises on one hand; St. Endellion, far away to the south, thrusts its square tower into the heavens; St Mabyn, one of the highest Cornish towers, rears well up into the horizon; while right across the bay, presiding above the foam, Tintagel church stands stiffly upon its headland eight miles away. The observer will not see the charming little church of St. Kew. It is hidden in its bower of pine and oak trees, deep in its own little combe. The down runs up from its south transept, the cross upon the roof of which is on a level with the roots of the elms which crown the summit. The church is early fifteenth century, and was restored somewhere about 1880. The old cradle roofs still remain, stained almost black with age, but its great attraction is its tower. To see it backed by the pine and elm foliage, with a declining sun full on its grey granite stones, each one marked by the weather, with soft yellow patches of lichen and tufts of spear grass growing high up from its arcades, is a picture not readily to be forgotten. A tapering stair-tower and turret runs up the whole height of its north side, rising with battlements above the main tower, while a rounded rain-worn labelling clasps it at the level of the arcading. It is perfectly simple, and yet the fascination it exercises is quite indescribable. To look down at it, a dull grey gem in its rich green setting of foliage, gives a deep thrill of satisfaction not to be accounted for by its architectural value. It contains a window made up from fragments of old glass of the middle fifteenth century, which is worth notice for its brilliancy and from the fact that little stained glass has been spared from pre-Reformation times.

MAWGAN CHURCH.

MAWGAN CHURCH.

The quaint little church of St. Petroc Minor is, like St. Kew, regarded as of scant interest; for little mention is made of it anywhere, and it is impossible to get photographs of either of them, yet St. Petroc, like St. Kew, would fascinate the artist-architect. Great bushes of hydrangea covered with bunches of pink and white blossom lean against its walls. It was here I was requested "to keep close the fish nets over the door or else the swallows would get in and disturb the worshippers." In this church is a picture covered with a cloth screen, about which I could find nothing. It looks rather like one of the old Dutch masters, and yet seems too modern in its treatment to be genuine. A seated figure of a woman almost whelmed in shadow looks out from the canvas. The face is powerfully formed—a pure, rather plump, type of low Dutch, with startlingly clear eyes. The only other things in the picture are a book and a skull; and what the subject idea was I could not guess. It was sufficiently strange to meet such a picture in the little church of St. Petroc, even though it is mentioned in the Doomsday Book. But greater anomalies than this are to be found in some of the Cornish churches.

They can be taken in any order, these churches, when driving about the lovely Cornish lanes with their huge massed hedges of briar and bramble and innumerable wild flowers. They usually convey a warning of their presence to the interested long before he reaches them, their square grey towers, and spires in a few cases, quietly drawing the attention to them, over miles of placid landscape. Only when they are completely bowered in trees, like St. Kew and St. Mawgan, or hidden away among the sand dunes and behind the tamarisk, like St. Enodock, do they escape the eye.

St. Enodock is most quaint of many Cornish churches. Approaching it from Rock over the piled sand hills, it is blotted out completely until Bray Hill is reached, a sandy eminence overlooking the doom bar of sinister memory to sea folk. Letting the eye sweep beyond Polseath, it is met by the stern headland of Pentire, which when seen with its feet in the foam and its crown in a cloudy glory of sunsetting, will draw many a sightseer to ignore the little church of St. Enodock that lies almost at his feet among the sand dunes. This church is, like most of middle fifteenth-century origin, built of grey granite of great thickness, and so tiny that it seems the nave alone—it has no aisles—would only hold about twenty persons abreast. It contains a Norman font of simple design, supported on four pillars capped with clearly-cut heads, and with a thick cable mould at the base. It is much too large for the present building, which stands on the site of an old oratory to which it probably belonged. A feature of its churchyard, beset by a high sandy wall, is the collection of granite piscina lining the path to the door. There are some old slate tombstones lately uncovered, deeply cut in relief and extremely well executed. Their inscriptions alone are well worth a visit, hinting as they do at the life of the wild crew which smuggled, engaged in mild piratage and drew vessels to their doom upon the rock-bound, sand-set coast. The church has been almost completely buried by the shifting sand, wind-carried from the doom bar; and a tale is told of a dear old vicar who, to collect his dues, excavated to a window, and from it read the lessons, so setting the example to its future excavators. The strange little crooked tower, with its truncated top, has its separate legend; for when the first service was read, after its hundred years and more of burial in the sand, the name of Our Lord drove the Devil pell-mell, helter-skelter out of the building by the tower, from which in his extreme haste his cloven hoof struck off a piece, and, as the tale is repeated, so it can be seen to this day.

It will be impossible to mention all the churches of interest: the little chapel of Saint Michael of Rock must be passed over. St. Breock again, with a fine Decorated tower and font, must be left also, while Padstow can only have a passing reference. It is a beautiful church, with a square strongly-based Early English tower, the old timber cradle-roof still remaining with some old glass in the windows of nave and aisles; yet the charm of the place cannot be expressed in architectural terms. It lies in the churchyard enclosed and cut off by masses of foliage from the town; the tombstones lying all ways, the shaped yews, and conical firs presided over by the tower, lend an air to the place which cannot be described. Passing from the south, north along the coast road, the little village of St. Teath is met on the road to Camelford. To reach the church you walk between tiny leaning cottages thatched thickly with straw, many of them heavy with masses of wistaria and jessamine. A crimson passion flower grew right up to the eaves of one, hanging over the windows and on each side of the doorway. The cottages are mostly built of the waste slatey stone from the Delabole quarries, sometimes without a trace of mortar between their joints. It is of a purple-gray colour, a very good medium for the weather to work upon, turning every imaginable tint after a few years. The church contains a powerfully carved and coloured pulpit of early seventeenth-century workmanship, not quite a success in its colour, and strangely at variance with the spirit of the cold, rigid little building. The east window of the south transept has some old heraldic glass of great richness, the shield of Henry VII. being conspicuous. Within the north transept an effigy of the thirteenth century makes a point of considerable interest comparatively. The strict architectural stylist would attack roundly here for any admiration expressed; for when put by the side of some specimens of French Gothic of the period, how lamentably it fails! It must not be judged in this way, however, for it is a speciality in itself, and can only be judged accordingly. There are many of the carved oak bench-ends still in a good state of preservation, all of an extraordinary versatility of design, and some with a quiet beauty which cannot fail to make its appeal. These are to be met with throughout the Cornish churches, St. Minver especially being distinguished by a great number. St.

Endellion also contains some beautiful specimens; but this church having been restored with far less care and solicitude than St. Minver, they have been spoilt by varnishing. The designs are mostly different, and include a scheme embracing almost all forms and ideas familiar with the people; one which is repeated in two or three churches good distances apart, and evidently appreciated, is that of a fox preaching to [some geese, the moral of which has been interpreted somewhat diversely.

The churchyard of St. Teath holds a huge Cornish cross in granite 15ft. high. It was until lately built into a fence in its separate pieces, but has been recovered completely and set up in the raised churchyard, from which it loftily overlooks the narrow lane. It is of the most usual Cornish type, a tapering granite shaft rising from a single step base, and speading out into a cross of slightly Maltese type, with a ring connecting the flanges. It is of a most happy proportion, seamed and scored by the boisterous weather, and is an imposing object from the narrow by-way. A cross most unlike the Cornish type I have met with is in Mawgan churchyard. It is very delicately executed, and very different to the rude strong crosses seen elsewhere. An octagonal shaft 3ft. to 4ft. high supports a canopy with four niches. One contains the Deity, with a crucifix between His knees; in the next are a king and queen kneeling at a lectern, beneath which an angel unrolls a scroll. An abbot and abbess occupy another niche. the mitre looking somewhat like a crown. Above the canopy, the stonework has been shattered, although there seems to have been a second and smaller canopy which terminated with some form of pinnacle cross. The date of this is about 1340, and it was, I should think, executed outside Cornwall.

The famous "grey convent of Lanherne," near the lovely Carnauton Woods, has an ancient runic cross in a small corner shubbery of its grounds. This cross is of unquestionable antiquity, the shaft sculptured with intricate knotwork twisting in mazy ordered coils upon all of the four sides. Upon the face of the cross itself, and in rude relief worn away almost past human resemblance, is a small figure, evidently purporting to be that of Our Lord. This cross is unique of its kind in North Cornwall, and within its tiny enclosure adjoining the nunnery is most striking. This nunnery was originally the old manor-house of the Arundels, and parts of it date back to the twelfth century. It is a most beautiful building, containing wonderfully carved and panelled interiors, which now unfortunately are closed to the public owing to an insult given to one of the nuns by an ill-mannered boor, who took a bet that he would kiss one of the inmates. The chapel and part of the grounds were until last year still left to be visited, and the long front of the building, with its great Gothic bays, its rich arched doorways, carved lead guttering and edging, the heavy rainwater heads of beautiful design and execution, form such a picture as would warrant alone a visit to this part of Cornwall. The chapel has since been closed to the public, consequent upon the unseemly behaviour of the public within it at a ceremony when a novice was "wedded to the Church." It is an interesting building, fitted up in the style of Louis XIV., but is not to be compared to the nunnery wing. It contains a picture of the Flagellations of Christ, attributed to Rubens, and though it is in the style of his work, there is little doubt that, even if of that period, it was executed by one of his numerous "pupils" rather than by himself.

ST. ENODOCK CHURCH.

All this while within the grounds of the "grey convent of Lanherne," the splendid church of St. James Mawgan rises in full view of us. I use the word "splendid" advisedly, for among the churches of North Cornwall, Mawgan comes next to St. Columb Major as one of the most beautiful. Its position goes some way towards making it supreme, but the church itself can make its claim alone, without aid from its situation. The building is Perpendicular throughout, and the fine tower stands 80ft. clear from the level of the nave. The stair-tower finished with the charming little pinnacle turret rising high above the battlements is a feature of many Cornish towers, the one of St. Kew terminating in battlements alone, which mount above those of the main tower. High up, and rising to the labelling below the battlements, masses of climbing and tree ivy grow right out of the crevices of the stonework. A curious detail of the tower is a built-up doorway at a height of 30ft. or 40ft. in the south side, the use of which I could not gather. This church was restored by Butterfield, and although successful on the whole, the contrast between the restored and unrestored windows in the east end is rather painful. The interior contains part of an old rood-screen, the altar side of which is most richly carved in high relief. Many old bench-ends remain, some far exceeding any I have seen for quality of design. The capitals of the columns have a banding below the abacus, running round with a heavy leaf-work cut in it: this is an idea carried out in many Cornish churches, some, indeed, having the identical detail although thirty or forty years separate their dates. The font is modern in its mounting, the basin with its four carved heads being of Norman workmanship and discovered in the churchyard.

(*To be concluded.*)

ST. ENODOCK CHURCH, CORNWALL.

THE EIGHTEENTH-CENTURY ARCHITECTURE OF BATH.*

BY M. A. GREEN.

IN this paper we are mainly concerned with the period between the years 1727, when the elder Wood came to Bath, and 1781, the date of the death of his son. But it is necessary to review the work which preceded and which followed theirs.

A Dr. Johnson's view of Bath as it was in the year 1572 shows the city surrounded by its walls, of which there are now few traces except in name. The size of the city at this time was about 1,200ft. from east to west and 1,150ft. from north to south. By 1590 the city was much enlarged, and by a charter granted by Queen Elizabeth extended from the bridge over the Avon at the bottom of Southgate Street along the middle of the river as far as the meadow called Kingsmead, and thence to the highway leading from Weston to Walcot, and so to the Win Yards, or Vine Yards, thence by Walcot Churchyard, and so along the middle of the river back to the old bridge.

A word here as to the Bath waters. Wood says in his "History of Bath": "About the latter end of September in the year 1663, the King (*i.e.*, Charles II.) brought his Royal Consort, Queen Catherine, to Bath; Sir Alexander Frayser, as chief physician, attending them hither, who, upon finding the hot waters to be from the same minerals as those of Bourbon, and that they could be pumped up directly from the spring, began to advise the inward use of them . . . From this period the drinking of the hot waters of Bath may be very justly said to have been established, and from the same period the trade of the city began to turn from the woollen manufacture to that of entertaining the strangers that came to it for the use of the hot waters."

In 1702 and 1703 Queen Anne and her Royal Consort, the Prince of Denmark, came to Bath. In the following year Dr. Oliver began to write on the Bath waters, and in consequence the Corporation improved their surroundings somewhat, but they still fell short of the Doctor's wishes, and in 1707 he published a practical dissertation, at the same time recommending the making of a cold bath for the use of the public. About this time Parliament was applied to for power to amend the principal roads leading to Bath, to pave, cleanse, and light the streets, lanes, &c., of the town, and to regulate and license a sufficient number of chairmen, that nothing might be wanting for the public utility of the city. "Twenty years," says Wood, "had now been spent in improving the private buildings of the city; in the course of which improvements, thatch'd coverings were exchanged to such as were tiled; low and obscure lights were turned into elegant sash windows, as soon as Mr. Taylor (who was, by the way, a chairman) had set the example: the houses were raised to five and more storeys in height; and everyone was lavish in Ornaments to adorn the outsides of them, even to profuseness." But with all this splendour little attention was paid to the wants of the company that assembled at Bath until Harrison's rooms were built in 1708. In spite of a reaction on the part of the citizens because of the increase in the numbers of the houses, Mr. George Trim, a member of the Corporation, and whose mother was a near relative of Inigo Jones, began in 1707 to build the street named after him at the north-west corner of the city.

The houses about this period are characterised by the large windows with projecting wave mouldings round them. Of such is the Saracen's Head in Broad Street, with the initials W. D. and date 1713 upon it. It was here that Dickens used to stay. The oldest house in this street is No. 38, date 1709; and almost identical with it in elevation is one in Chapel Court. I think these are by far the best of the older houses in the city.

In 1716, on the site of the new bowling green, a row of houses was begun, and was called Green Street. It is one of the most picturesque parts of Bath now remaining.

Meanwhile another citizen had been building in the south-east corner of the city. In a house in St. James Street South small panes of glass still remain in the lower windows; these make at once a feature in the design, whereas in the upper lights, where plate glass has been substituted, the windows seem to lose their identity with the building. Hard by is Weymouth House, which was built in 1720 for a Dr. Bellinson, and was designed by William Killigrew. An almost exact copy of Weymouth House is to be found in No. 3, St. James Street. Nearly opposite to Weymouth House is a curiously rusticated building, which was once Crutwell's "Bath Chronicle" office. The Orders are used, as seen frequently, to make a central feature, but the treatment is not good.

---

* Summary of a paper read before the Architectural Association on April 19th.

We must here notice old Widcombe Manor, built for Mr. Philip Bennett's son in 1727. The builder was likely to have been the Thomas Greenway who put up Beau Nash's house in St. John's Court, now the theatre. The garden house here is a refined piece of work. From a comparison of this building with the Palladian Bridge in Prior Park I am disposed to think they are by the same hand, and that if the Palladian Bridge was designed by Wood, then this little house was also. The building called the Garrick's Head, and known as the Theatre, was at one time the residence of Richard Nash, M.C. of Bath. Nash had a chequered career. Born in Swansea in 1674, he went to Oxford at the age of sixteen, and, having tried the law and the army in turn, finally entered the Temple. In 1704, however, he came to Bath, and on the death of Captain Webster he was appointed M.C. This house, situated in what was known then as St. John's Court, was built in 1720 by the Thomas Greenway above mentioned and after whom Greenway Lane is named. After Nash's power had declined he removed to another house just north of the last, and here he died in 1761.

PADSTOW CHURCH.

On the other side of the theatre are Beaufort Buildings, which Wood says are the piratical architecture of a Mr. John Strachan, a friend of Mr. Hobbs, a timber merchant, of Bristol, whom we mention below. Londonderry House and Kingsmead Square were also built by Mr. Strahan.

In 1723 another Act was obtained for Bath relative to lighting, cleansing, and other things, and to make the former Act more effectual; and "in 1724," says Wood, "a subscription was opened by Mr. John Hobbs, a deal merchant of Bristol, for carrying the navigation of the river into execution, so that when I found the work was likely to go on, I began to turn my thoughts towards the improvement of the city by building; and for this purpose I procured a plan of the town, which was sent me into Yorkshire in the summer of the year 1725, where I, at my leisure hours, formed one design for the ground at the north-west corner of the city, and another for the land on the north-east side of the town and river." Little is known of John Wood's early life. He was born in 1704, and it is probable that he was introduced to Bath through the influence of Ralph Allen. "After my return to London," he continues, "I imparted my first design to Mr. Gay, an eminent surgeon, in Hatton Garden, and proprietor of the land; and our first conference was upon the last day of December, 1725. On March 31st following I communicated my second design to the Earl of Essex, to whom the land on which it was proposed to be executed then belonged; and in each design I proposed to make a grand place of assembly to be called the Royal Forum of Bath; another place, no less magnificent, for the exhibition of sports, to be called the Grand Circus; and a third place, of equal state with either of the former, for the practice of medicinal exercises, to be called the Imperial Gymnasium of the City." In May, 1726, during the consideration of the drawings, a great fire broke out in Horse (or Southgate) Street, and the larger houses that took their place were the last built before 1727.

In November of 1726 Wood fixed his preliminary articles with Mr. Gay, who then empowered him to engage with anybody that he could bring into the scheme for the building of a street 1,025ft. long north to south, by 50ft. east to west, for a way to the grand part of the design. This was Berton Street, but at first it did not go forward, and Wood having two other schemes on hand, and finding it necessary to have good workmen, determined to become his own contractor. The first scheme was the building of a court of houses for his Grace James, Duke of Chandos, and the second was a canal between Bath and Bristol. For the canal he obtained men that had been on the Chelsea Waterworks; and he says "that until that time the real use of the spade was unknown in and about the city." "I likewise," he says, "provided masons in Yorkshire, carpenters, joiners, and plasterers in London and other places, and from time to time sent such as were necessary down to Bath to carry on the building that I had undertaken; and it was then, and not till then, that the lever, the pulley, and the windlass were introduced among the artificers in the upper part of Somersetshire, before which time the masons made use of no other method to hoist up their heavy stones than that of dragging them up with small ropes against the sides of a ladder."

At that time he was asked to prepare plans for dwelling-houses, an assembly house, and a general hospital, and in 1727 he left London altogether, and followed his workmen to Bath. In 1727 Chapel Court was begun. The house to the left is that in which Horace Walpole lived in 1765, and the wing to the right St. John's Hospital or the Blue Arms, designed by Wood in 1728.

The death of the King (George I.), however, causing Mr. Gay to fall from his bargain, and the Corporation making light of Wood's schemes, the latter dropped his agency, became absolutely his own master, and took ground from Mr. Gay for the building of Queen Square, so named in honour of Queen Caroline. John Street took the place of Barton Street, and Barton Street was what is now the east side of Queen Square and part of Gay Street, as well as the portion to the south.

At this time (1728) he was building an addition to the north side of R. Allen's town house in Lilliput Alley, putting also a new front to and raising the old building a storey higher. There was thus a basement storey and, as in Queen Square and later on by his son in the Crescent, an order rising through the two storeys over with one crowning cornice, and he says that it was "a sample of the greatest magnificence that was ever proposed" by him for the city houses.

In 1730 the houses of the Duke of Chandos, called Chandos Court, were being erected. They were to form three sides of a square with a garden in the middle. Chandos House had been rebuilt in 1727 for the Duke.

Queen Square was in reality Wood's chief delight. The first side built was that on the east, which was begun in 1728. The whole was finished in seven year's time, including the chapel and many houses adjacent. The width of the square from house to house is about 315ft.

In making the grand façade, as we may call it, on the north of the square, it was to be, as it were, a palace, and the east and west sides the wings. The original intention is shown in the plate in his own book. The design, as usual with him, was a simple one—a rusticated basement with the Corinthian order over and a large crowning cornice just as in Ralph Allen's house, and yet from its treatment so different in effect as was fitting to a widely extended façade such as this. The windows have alternately triangular and circular pediments, as in a similar storey in the Farnese Palace at Rome. A bronze tablet has been lately put up on the centre house to mark the residence of the elder Wood. It was here that he died on May 23rd, 1754, and here also his widow deceased some twelve years later. There was no shirking of finish in the case of John Wood's builders, though the work was often of a speculative nature. At the south-west angle of Queen Square stood the chapel of St. Mary, begun in March 25th, 1732 and completed at the end of 1734. Ionic capitals from the interior yet remain on the site of the chapel.

In 1729 Wood built a villa called Eagle House at Batheaston, where he lived for some time. The house has been much altered. The younger Wood died here in 1781.

While mentioning the works of Wood outside the city, it will be well to include two or three more houses which he built at various times. The little house called Lilliput Castle was built by Mr. Jerry Pierce, in the year 1738, against the north end of Mons. Badonca, that is, Lansdown, and formed the nucleus of what is now known as Battlefields. From its form the wits of Bath called it T. Totum. The whole structure was but 120ft. square. It suffered two fires, and was afterwards altered.

At the south end of the Kingsdown at Bradford-on-Avon stands Belcombe Brook Villa, built in 1734 for Mr. Francis Yerbury. The situation is extremely pleasant, the grounds sloping down to the river Avon, and it was here that Wood showed himself to be a master of landscape gardening. To the right of the courtyard is a stone-built dovecot, and the paving in the courtyard is as originally laid. From each angle of the house a balustrade runs diagonally into the garden, following the slope of the grounds.

At Bathford, on an eminence of Kingsdown and looking north-west, is to be found one of the most finished of Wood's buildings. Titan-Barrow Loggia was erected some fourteen years after Belcombe Brook Villa, in 1748, for Mr. Southwell Piggott.

The mansion of Prior Park was the largest and best work of Wood, and was begun about 1735. Let him speak as to its origin: "The reflection cast upon the freestone of the hills of Bath brought him (Mr. Allen) to a resolution to exhibit it in a seat which he had determined to build for himself near his works, to much greater advantage and in much greater variety of uses than it had ever appeared in any other structure. Thus it was that Ralph Allen, whose little house in Lilliput Alley we have seen, came to build himself such a vast country mansion." The scheme of the design was three-fold—a central mansion with east and west wings and a pavilion placed between these three more important buildings, the mansion occupying about 150ft., and the whole line of building from end to end about 1,200ft. or 1,300ft. in length. The south side of the mansion facing up the hill towards Combe Down, and at a height of about 460ft. above sea level, consists of a hexastyle Ionic front with attached columns and this forms the entrance. The north side, looking towards the city is a fine front and is full of detail. In the first place the natural slope of the ground allowed of the basement being entirely exposed. Wood never intended the flight of steps as now seen, although I cannot help thinking that this has added greatly to the dignity of the building. The fine projecting hexastyle portico was intended to be a rival, and something more, to the one which the architect Colin Campbell had erected at Wanstead House, in Essex; for whereas that one had columns of 3ft. in diameter, these were 3ft. 1¼in., and on the return side are two complete intervals between the columns, instead of one and a small portion of another as at Wanstead.

Prior Park was finished in 1743. Two fine sweeps of stone steps with balustrades and vases form an architectural treatment of the gardens below the great portico. They were executed by Bishop Baines about 1830. At the foot of the slope lies the Palladian Bridge, considered to be the work of Wood. Here are the old fishponds once belonging to the Priory of Bath, and from which Prior Park takes its name.

When Wood's scheme for building a grand parade on the south side of Queen Square was abandoned, and Wood Street, which had been intended to be 100ft. wide, was reduced to about half that amount, Wood turned his attention to the large space at the south-east side of the city, and began to lay out his ground and buildings on a large scale. This space was the old Abbey Orchard. The first stone of the first house of the Grand Parade (now North Parade) was laid on March 10th, 1739 40. The Royal Forum, or South Parade, was begun in January 1742-43.

South of Ralph Allen's town house, and little known or appreciated, there lies a large court built by Wood, with good houses on either side, of about date 1740. They are North Parade Buildings, formerly called Gallaway's Buildings.

There seems to have been considerable difficulty in the commencement of the Mineral Water Hospital, called then the General Hospital. The site at first proposed in 1727 was on the north corner of the Ambrey, but the first stone was not laid until July 6th, 1738, on a site in the north part of the city. The hospital was finished in 1742. The stone and other materials for this building were provided by Ralph Allen. Although Wood prepared the designs for the Grammar School in Broad Street, it is not known that he executed the building.

The "History of Bath," published by John Wood the elder in 1749, though in part a chimerical work, is a valuable addition to the records of the state of the city during the first half of the eighteenth century.

Gay Street was designed by the elder Wood, but executed by his son, and it was in the house at the corner of Queen Square and Gay Street that the younger Wood lived. The panel on this house shows that John Wood the younger was born in 1727 and died 1781. The Circus was also designed by the elder Wood, and carried out by his son. The buildings were begun in 1754, and they took fifteen years in completion.

The æsthetic sympathy of the younger Wood with his father is a remarkable feature in his buildings; and it seems to me not unlikely that as Gay Street and the Circus were the designs of the elder Wood, they may have conferred together as to the buildings west of them, and that the younger Wood may have been guided in their development by the advice left him by his deceased father; at any rate, in the Crescent exactly the same use of the order is seen as in Queen Square, though less elaborately worked out, and in the Assembly Rooms the broad treatment of spaces externally and internally is observable, as in the work of the elder Wood. It should be noted that originally the roofs, as indeed the roofs throughout Bath, were covered with stone tiles, and a more artistic covering can hardly be conceived. The eye is thus carried up to the topmost part of the building, and sees it as one harmonious whole. The Crescent, which, as we have seen, was the work of the younger Wood, whose buildings we are now considering, was begun in 1767, but not finished till about eight years after. The diameter of the Circus from house to house is about 320ft., and the major axis of the crescent (an eclipse on plan) 550ft. It appears to have been the intention of the Woods to build another street beyond the Crescent, and another Crescent beyond that again, but Marlborough Buildings effectually put an end to any such scheme. Brock Street was the work of the younger Wood, and connects the Circus and the Crescent. In it is Margaret's Chapel, which has a good Venetian window overlooking the street.

The first stone of the New Assembly Rooms in Alfred Street, on the east of the Circus, was laid by Wood in May, 1769, five years after the proposal to build a somewhat similar set of rooms at the north-west corner of Queen Square. The rooms were finished in 1771, at a cost of £20,000, on the ground covering over an acre and a half. They were formerly called the New, or Upper, Rooms. The planning is exceptionally good.

Alfred Street was also built by Wood.

It is probable that about 1776 Wood rebuilt the Leper's Bath, adjoining the Hetling Pump-room. This is a piece of work which is little known. About the same time he built Woolley Church, near Bath, the cupola of which is worthy of note. In 1779 he built Hardenhuish Church, near Chippenham, a cleverly-designed piece of work.

Before leaving the history of the Woods I should mention that the Exchange in Bristol was by Wood senior, erected 1740–43; also Redland Court, in the same city, the latter with terraces in the Italian manner. Shockerwick House, near Box, was built by him in 1750.

There still remain many interesting buildings in Bath which must not be passed over. Milsom Street was probably designed by Robert Lightholder about 1760. He at any rate designed the Octagon Chapel there, which was opened in 1767. About this period the Corporation had to rebuild the old Town Hall, and one Thomas Attwood, who about the year 1762 had built a family house for the Pulteneys in Grove Street on the farther, or Bathwick, side of the river, was instructed to proceed with the matter. This house afterwards became the gaol, and, considering that Attwood's trade was that of a plumber and painter, it shows no little talent. He died, however, from the effects of an accident while the old houses near the Town Hall were being cleared away, and shortly afterwards, in 1774, a plan for a town hall and markets was offered by Thomas Baldwin, who was then only twenty-four years of age, having been born in 1750. These were approved by the Corporation and carried out. Thus Baldwin became the chief follower of the Woods. In 1780 he was made city surveyor, and four years later city architect. Baldwin's work has not the strength of that of the Woods, but depends more on surface decoration. The building was completed in 1777.

Passing down Bridge Street we come to the Pulteney Bridge, which was built about 1776 from designs by Robert Adam for his patron, William Pulteney, Earl of Bath, that he might have the more ready access to his Bathwick estate.

Beyond this the domestic work of Baldwin is principally seen. In 1788 Laura Place was commenced. Great Pulteney Street, which was begun about 1792, was his finest work.

The old Pump Room had been finished in 1706. It was much enlarged in 1751. Previous to 1780 Reveley had been commissioned to prepare plans, and work was commenced and carried to a considerable height at the west end. On the appointment of Baldwin as city surveyor in that year, however, the work was stopped, and he in his official capacity had to prepare plans. In 1788 a committee was formed to discuss them with him, together with the estimates, and work appears to have commenced; but difficulties arising between him and the Corporation, it was again suspended. In 1794 John Palmer gave new plans and elevations, and in 1799 the new Pump Room was finished under his direction.

In about 1790 Reveley had built Camden Crescent, remarkable for the manner in which the rise of the ground is overcome in the design.

In 1789 an Act of Parliament had been obtained for the improvement of the older part of the city, and much was done within the next few years. A new street was built to connect Milsom Street with Stall Street, as formerly the back part of the Bear Inn premises served for this purpose. This was Union Street; Cheap Street and Westgate Street were widened, and Bath Street was built, all under Baldwin.

A New Sailors' Home at Chatham is being erected at the top of the Military Road, near the Town Hall, from the designs of Mr. G. E. Bond.

TO IMPROVE WESTON.

THE NEW PAVILION SCHEME.

A GREAT many schemes have been mooted at one time or another with the object of improving Weston-super-Mare as a seaside resort. One was a Transatlantic port at Brean Down for mail steamers, which was to earn for Weston an international reputation. This progressed farther than most of the other ideas, for the foundations of the harbour were put down before the undertaking was abandoned. A long time afterwards there was a big meeting in the town's assembly rooms, when the scheme was resuscitated, but that was ten years or more ago, and nothing has come of it yet. Later Parliamentary powers were obtained for the erection of a pier running from Regent Street, opposite the centre of the bay, to low water. It was a big undertaking on account of the tremendous length of the proposed structure, and eventually the powers lapsed. A time extension was obtained, but to-day the pier is still a proposal, and the extended powers must be again near lapsing. Another pier project followed. This pier was to run out from Knightstone, but, like the proposals for electric trams running parallel with the promenade, a big wheel, and so on, it fell through. To construct marine lakes such as they have at Southport was another ambition, but, beyond illustrations in the local papers and various surmises as to the outlay, nothing came of it.

The great impediment to the improvements, good and bad alike, has been the cry of the tripper. Weston's all-pervading bogey has been the tripper, and anything that suggested an encouragement to him was cried down. There is still the excursionist bent on an out-and-out day's holiday who makes a mad rush for the sands at the end of Regent Street, and patronises every imaginable penny gaff, but there are others who spend their evenings in Weston, who do not find donkey rides and halfpenny ice-creams, consumed without the aid of spoons, indispensable: and it is for these latter that provision is now to be made. The first step has been to provide a pavilion. Knightstone, the site of the swimming baths, was acquired by the town some years ago, and here a good deal of money has been expended on improvements in providing a pavilion and up-to-date swimming baths. To prepare a site for the pavilion a retaining wall was built, which increased the area of Knightstone by a quarter. The pavilion will be a great acquisition to the town, especially as a thoroughly modern convenient building is being put up. There will be accommodation for 1,200 seats besides promenading space, good stage-room, convenient waiting-rooms, cloak-rooms, and lavatories. There are two floors. The concert hall is 100ft. long by 67ft. wide, with a gallery running round. The building itself is a solid structure, in which there will be a good deal of terra-cotta work. Beneath the pavilion a large settling tank has been excavated, in which sea water will be stored for the supply of a modern swimming bath, which the Council are going to build in proximity to the pavilion and adjoining the present baths. The bath will be 100ft. by 35ft., and will be provided with eighty-four boxes, club dressing-rooms, and a three-side gallery. This, too, will prove an acquisition for Weston, where the provision for aquatic sports and polo matches has not been the most admirable. The new baths will have accommodation for 400 spectators. The expenditure involved on the pavilion will be about £10,000, and the work will be finished this season, but the new baths will not be ready until next year.

Upon the promenade a series of improvements are being effected. Chief of these is the alteration of Madeira Cove. The curve is to be accentuated, so as to give more seating accommodation and greater promenading space, whilst a smaller cove will be made on the other side. The Council have purchased a portion of the gardens adjoining the promenade between Madeira Cove and Anchor Head, which they will utilise in widening, and at Anchor Head or Pebbley Beach a kind of transformation is being worked. The surveyor (Mr. H. Nettleton), who is carrying out the work, is providing rockeries, &c., so as to give the promenade as varied an appearance as possible.

COLD STORAGE.

THE PRINCIPLES OF CONSTRUCTION.

THE preservation of dead meat and other eatables for lengthened periods of time has lately become a matter of great importance to all classes of the community.

What was thirty or forty years ago a luxury in the form of ice safes, used only by a few high-class provision-dealers, butchers and fish salesmen, has become a matter of common usage.

From the builder's point of view, it is a matter of comparative indifference what system is adopted in cooling or chilling the meat. His task is to so build the cold store that outside heat may not get inside so as to neutralise the cold superinduced by the plant and machinery of the establishment, and, what is of perhaps equal importance (for a greater expenditure of energy on the part of the plant and machinery can generally, though at unnecessary cost, make up for the builder's defective insulation), to exercise such care in regard to his foundations and interior walls that no smell or damp or other deleterious elements may, from the outside or from the composition of the walls, reach the interior of the chambers where the meat is stored. If the builder fail in this, then, in proportion to his failure, so is thrown away the genius and care of the engineer who has put down the cold-producing plant and machinery.

That the builder may the easier grasp his problem, a short description of the principle and application of cold production may be given. Cold or absence of heat is arrived at in nature, as well as artificially, by a process of porterage. Gases absorb heat and carry it with them in great volumes, and very rapidly : so will liquids. Thus, if you place a lump of ice in a warm room, it will melt under the heat, and the melted ice —water—will take away with it a great proportion of the heat used in bringing it into liquid. If the water be taken away from the room, the room will be by so much cooler, not by reason of the ice left in the room, but because of the heat absorbed and retained in the removed water. If the builder so constructs the room that no additional heat can get in to take the place of that retained in the water, he has effectively done his part of the cold store, as far as insulation is concerned. Now, variable winters affect the ice harvest and its costs just as variable seasons affect the harvest and cost of corn ; but mechanical refrigeration (or better called "artificial") pursues its level way indifferent to the seasons almost—always allowing that heat or cold, in so far as either calls for more or less artificial effort, naturally affects the total cost of a year's working ; yet the cost per unit does not vary with artificial cold as it does, and must do, with natural ice.

The principle most in favour now is the gasification of ammonia, sulphurous acid, or carbonic acid. The cooling agent is first compressed. The compression imparts heat to it, so that when it is freed from its compressed state it flies off in gas and speeds through the piping (gas-tight, of course) judicially distributed through the room that is to be cooled, capturing (absorbing) heat in its course, and ultimately being led out of the cooled space to be in its turn condensed in cooling coils, by parting with its acquired heat to the circulating cold water in which the coils are placed. It, the cooling agent, is then once more ready to be compressed and sent on its heat-capturing mission through the cold room or store, as before. That is the direct expansion principle. Another way is to use ice or the gas to cool a quantity of salt water (brine) in a vat. This, when cooled (not being noxious like the gas), may be run naked in open channels through the cold store, absorbing heat and moisture as it goes on ; leaving the cooled stores it gets rid of its heat, and recommences its course. Thus, like the gas, going in a perpetual circle, just lingering at one part on the way to get its heat taken from it. Thus is cold produced, subject naturally to the various modifications that the fancies of the proprietors or engineers, in their never-ceasing endeavours to improve things, may introduce.

The rest of our observations will be devoted to the construction of the foundations and walls of cold stores, in regard to which must be kept in view not only the exclusion of heat, but also the exclusion of vapours or smells emanating from the outside, or even originating, as is frequently the case, in the materials used in the construction of such foundations or walls. This latter is of much greater importance than appears at first sight ; for it has been proved by technical commissions, appointed *ad hoc*, that the almost imperceptible odour of foreign stuffs, healthy or unhealthy, is greedily taken on by the meat, which so tastes as to "spoil its market." So much is this so that the goods stored have to be classed and stored in separate chambers. Fruit should not be stored with meat, else the latter may taste, say, of apples—and so on. It is obvious, therefore, that the builder of a cold store must see to it that the interior surfaces of his cold-store floor, walls and ceiling are so faced that nothing not specially introduced may come into contact with the articles stored.

It is obvious that, in the matter of a cold store, site counts for much. The situation should if possible be dry, high lying where convenient, and yet as little exposed to winds and sun as possible. In a large town a site cannot easily be chosen, however.

It must be admitted that cold stores do not, as a rule, boast much architectural beauty. Stores of any kind do not generally pretend to anything but the largest possible efficient cubic contents for the cost of enclosing the same. As a matter of fact, the only peculiarity in a cold store, from the builder's point of view, is insulation. This, however, if properly carried out, means an immense reduction in space available as compared with non-insulated stores. A fire-proof safe is a fair example of what has to be done to insulate a cold store, and the material used to prevent fire reaching the documents in the safe may likewise be used to maintain a cool temperature in a cold store : that is, prevent the exterior heat from entering. Perhaps we should observe, parenthetically, that, once the store is cooled, it must not be supposed that all the heat to be "kept down" comes through the foundations, walls, windows or roof. The goods stored give off much heat, and that has to be taken away. But such removal belongs to the engineer's province, not to the builder's.

The site for the cold store having been chosen, the foundation is the next consideration. The insulating mediums are various, and the changes are rung with them according to the fancy of the architects. The following foundation was laid for the Dundee Cold Stores : A bed of dry ashes ; 6in. of concrete ; 1in. of bitumen ; 9in. of granulated cork ; and $1\frac{3}{8}$in. white-pine flooring boards tongued and grooved. Here we have 1ft. $5\frac{3}{8}$in. of insulating material between the interior of the store and the ashes, which may be any convenient thickness.

At this point it may be well to give an idea of the comparative insulating value of different materials. The specialist organ for refrigeration called "Ice and Cold Storage," in its issue for April last, published the following table showing the relative heat-radiating power of six materials compared with a brick wall, all 6in. thick :—

	Heat Units.
Firewood - - -	4·0
Cork chips - - -	2·6
Charcoal - - -	2·6
Sawdust - - -	2·2
Wood ashes - - -	2·0
Cotton - - -	1·4
Brick wall - - -	6·2

Of course, the chief danger from the foundation is moisture. The earth is more likely to absorb than to radiate heat.

Another table taken from "Ice and Cold Storage" (July 1899), based on a different system of calculations, shows (as can be seen by reference to those materials mentioned in both tables) that they bear practically the same relation to each other under both tests,

Relative Conducting Power for Heat as shown by the test of Melting Ice.

Silicate cotton - -	100
Hair felt - - -	117
Charcoal - - -	120
Wood shavings - -	125
Gasworks breese - -	230
Wood and air space - -	280
Sheep's wool - - -	136
Infusorial earth - -	136
Sawdust - - -	163

It is not to be supposed that, having established the most efficient heat insulators you can at once proceed with your foundation. The insulator may be of or contain an evil-smelling agent. In such case the greatest care must be taken to so dress the surface of the floor as to prevent such odour penetrating into the cold store, and careful dressing does not always settle the matter, for the constant foot traffic over the surface will soon wear holes in the upper skin of the floor (unless covered with wood), and so let in the smell perhaps of tar bitumen, which will soon render the stored meat so "tasted" as to make it unsaleable.

The accompanying illustration (Fig. 1) taken from the June, 1899, issue of "Ice and Cold Storage," showing section of foundation and walls of a Canadian cold store, conveys in itself a whole bookful of cold-storage information. For the foundation we have 12in. of cobble or broken stone ; 6in. sawdust ; 1in. rough boarding ; 2 layers of building paper ; and $1\frac{1}{2}$in. wood flooring ; total, $22\frac{1}{2}$in.

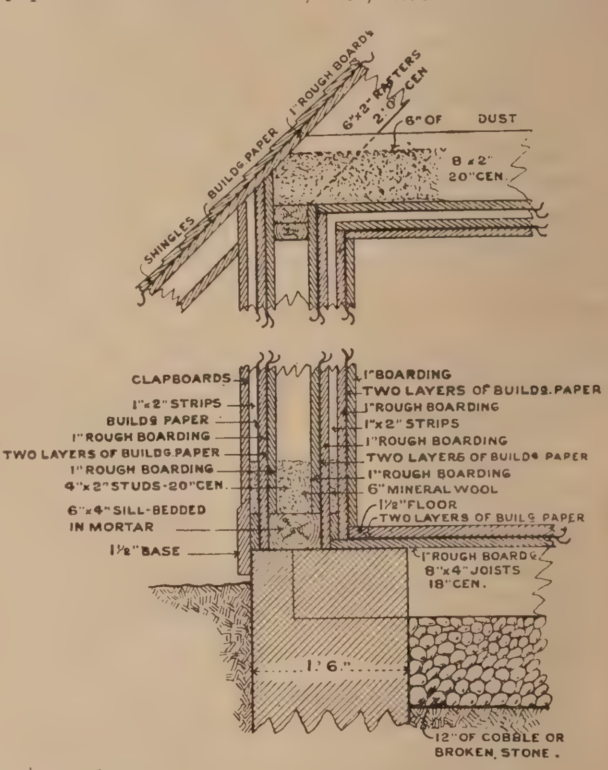

FIG. 1. SECTION OF A CANADIAN COLD STORE.

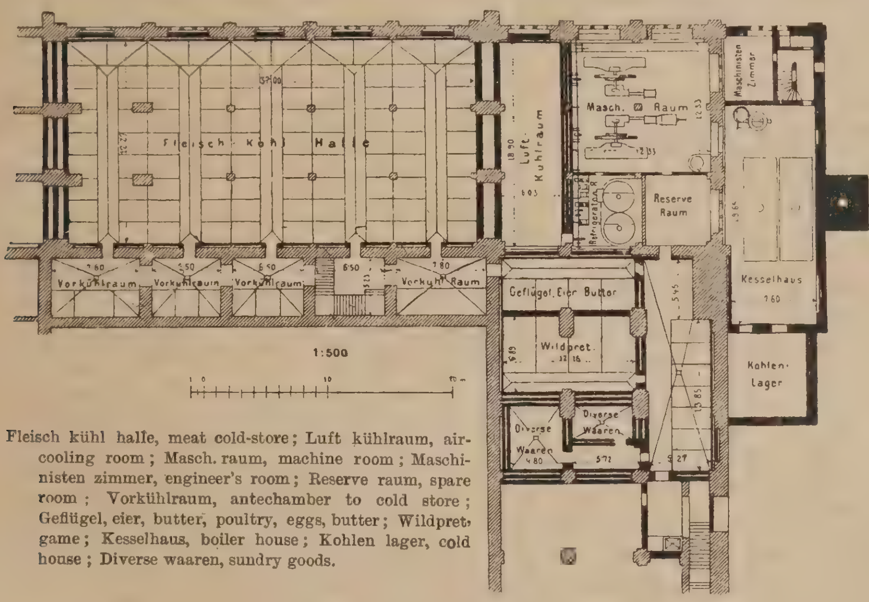
This for a foundation under the floor is not always thought to be enough. Some German authorities—and in Germany cold storage is as far advanced as anywhere, at least technically—require a full yard of insulation, largely concrete between the floor and the earth. Of course the foundations of the walls must be built solid to support great weights, and do not admit of the series of materials that may be chosen to go beneath the flooring. Solid masonry or brickwork naturally takes its place here, and must be accepted as the insulator, with such aids and felt as can be conveniently combined with it.

Now, before we leave the foundation, let it be carefully borne in mind that cold air being heavier than warm air, the cold-storage room should be lower, if anything, than the cold-generating room, be it by ice or gas, except where direct expansion is employed ; for, naturally, if the cold air lie lower than the store to be cooled, the said air will remain and refuse to circulate. It is sometimes otherwise arranged so as to obviate the condensed moisture in the cooled air chamber finding its way by gravitation into the cold store. But as the eminent German authority, Constanz Schmitz, points out, a properly-built cold store will be so waterproof, where required, as to make such a consideration wholly indifferent. One point particularly remains to be mentioned before passing on to the walls, and we cannot do better than quote Dr. Schwartz, probably the best living authority on the hygiene of cold-storage building. He says: "The position of gutters, gulleys and drains has also a substantial influence on the cold room air. The more care the builder of the cold room gives to this the better it is for the working. It is, of course, indispensable to have a sufficiently smooth and slanted floor, as also gutters correspondingly inclined. The gulleys, too, must be cemented at the bottom, and not, as I have occasionally found them to be, only walled holes without a solid bottom, allowing, of course, the waste water to easily sink into the ground and become a permanent source of bad smells. A good water trap should not be wanting."

The walls of the store now claim attention. The most perfect insulator known is dry still air. Therefore, a wall built containing a hermetically closed dry air-space is an ideal cold-store wall; but it must also allow for renewing the air contents. This will always shrink, and the wall is a very delicate one to make. We refer, then, back to the illustration, Fig. 1, to show a good well-studied insulation. There is:—1in. boarding interior; 2 layers of building paper; 1in. rough boarding; 1in. strips by 2in.; 2 layers of building paper; 1in. rough boarding; 6in. mineral wool. From the mineral wool to the open air we refer the reader to the section referred to. Of course, every wall, *i.e.*, including partition walls, must be an insulating wall, though the exterior walls most call for attention. It is a common thing, as in the principal Glasgow Cold Stores, George Street, to adapt an old building to the purpose. In such case the insulation becomes rather a carpenter's job. It is done inside, and most seriously reduces the cubic contents of the store. But, it is well to bear in mind, a cold store should not be larger than is required; for a deal of "cold" is thrown away where a larger cubic measurement is refrigerated than is needed. We need not dwell further on the walls. A builder's or a proprietor's fancy or desire to experiment will naturally suggest variations in insulation. Where the interior wall surface is cement, this should be carefully dressed wet. After thoroughly drying, such a surface will not permit either wet or smell to penetrate. But when we get to the roof on which the sun beats, there is no harm in having about 3ft. of insulation between the interior and the open air. It would be idle to recapitulate the names of the insulators that may be used. Slag wool should, however, be always considered. Wood shavings, cork shavings and sawdust also follow close on, in point of efficiency. Where slag wool is used it should not be crushed, thus destroying the air cells. One of its virtues, if not its chief, is the air it holds in suspense and consequently still. Damp or moving air will carry heat; dry still air will not.



Fleisch kühl halle, meat cold-store; Luft kühlraum, air-cooling room; Masch. raum, machine room; Maschinisten zimmer, engineer's room; Reserve raum, spare room; Vorkühlraum, antechamber to cold store; Geflügel, eier, butter, poultry, eggs, butter; Wildpret, game; Kesselhaus, boiler house; Kohlen lager, cold house; Diverse waaren, sundry goods.

FIG. 2. PLAN OF COLD STORE AT VIENNA.

Having at some length considered the essential elements of a cold store, we now consider a general plan. To gather information and guidance from a variety of sources, we will, instead of citing British stores, show the ground plan of the fine cold store recently opened at Vienna (see Fig. 2). For the convenience of readers, the German words appearing in the illustration, are translated below it. Little will thus require explanation. But the Vorkühlraum (porch) must be insisted on. This is a chamber, or series of chambers, leading into the cold stores, to obviate the latter being in direct contact with the open or other warm air. Otherwise the opening and shutting of the cold-store doors to receive or give out meat would mean the admission of a large volume daily of outside, and perhaps impure, air. The porch, therefore, though empty, is not thrown away, although it looks like waste space. Recently-built cold stores, such as those at Lochrinn, Edinburgh, do not omit this receiving room. The parallelograms shown in the body of the cold store represent lattice work chambers. The room is so divided to admit of spaces being let off to private people at so much a year. A butcher is thus able to secure for a period a fixed space communicating with one of the passages which run across the store, just as he might rent a house or room. In all other respects, bearing in mind the insulation which is not shown in this plan, it (the plan) speaks for itself.

It would lead us further than the limits of this article will allow to explain the arrangements to be made for cooling the air or brine, conveying it through the cold store, and getting it away again. One principle must be borne in mind. Cold air and brine will circulate by gravitation, and when wanted back must be forced back. Therefore, the "cold" should be higher than the store to be cooled; it is then optional on the part of the proprietor to reclaim the heated cooling agent, which he does in the case of brine, or to let it escape, which he does in the case of cooled air, which becomes over-heated in circulation; and it pays better to cool fresh air. Gas or acid, of course, he never lets slip if he can help it. It is always brought back, cooled in coudenser coils, re-compressed and returned to its work of catching up and carrying away heat.

As the cold store here illustrated is one of the best on the Continent, let us refer to the insulation of its foundation, *i.e.*, under the floors.

The ground was excavated to the depth of a metre (39in.). A 50 centimetre (19½in.) layer of clay was put down. Over this followed 30 centimetres of coke, then 15 centimetres of concrete, and lastly, 2 centimetres of asphalt. In the walls 10 centimetres space was allowed for air.

The power supplied to this store is steam, and the refrigerating machine, by carbonic acid, is equal to 135,000 heat units per hour, besides reserve power, about half the foregoing. The total storage superfices, exclusive of passages, is 821 square metres. The store is fully described and illustrated in "Ice and Cold Storage," May issue, 1899.

Light must also be seriously considered. Daylight is the best. It is most easily diffused. Electric light is the clearest artificial light, but, unfortunately, it throws very dark shadows. Gas and oil, because of what they give off, are practically inadmissible. Acetylene has still its spurs to win; its smell is "impossible." Generally electric light is the illuminant chosen, and as for the dark shadows, they must be closely watched. Let the cold store have as few as possible; for where darkness is, there filth gathers, and filth is a mortal enemy to a cold store.

As to the upper floors, they follow pretty much the lines of the ground floor. Frequently this latter is only used for loading and unloading, and for making ice blocks; the cold store proper being from the first floor upwards. In such cases the communicating areas, lift wells, &c., all require either isolation or to be the direct medium between the receiving room below and the store above. The receiving room must be cooled and insulated.

It is not generally known how rapidly cold storage is becoming a great industry. Scarcely anything perishable escapes its attention. The beef and mutton—not to say the game—of Australia is killed there and brought to Europe in refrigerated chambers on board ship, to be cold stored here till wanted, in quantities that would be incredible to the uninitiated.

Summer plants and flowers likewise are kept in ice to deck the rich man's dinner table in winter. The cold store brings the Canadian and Danish dairyman into almost direct communication with the British consumer—the cold store only intervening. The construction therefore, becomes of yearly increasing importance. Many eminent chemists and engineeers make the economical production of cold a constant study, but as yet only a few builders have made a study of helping the chemists and engineers by building houses that will admit the minimum of heat during the time they are in use. An eminent chemist some time ago said that, next to electricity, cold storage is the new industry that has made most progress during the last twenty-five years. As farming decreases in the country, and towns grow in size, the cold store becomes an institution that a new race of builders will take in hand if the existing ones do not at once include it in their regular series of calculations.

VICTORIA HALL AT CALCUTTA.

THERE is a very general feeling among Anglo-Indians and the thinking portion of the native community that a grave mistake is being committed in the adoption of the form which is proposed by Lord Curzon for the Indian National Memorial to the Queen. The unprecedentedly large subscriptions which are pouring in are to be devoted for the most part to the erection of a Victoria Hall in Calcutta. This hall will be simply a museum to house a scanty and insignificant collection of pictures, statuary, and objects connected with the history of India. These things are to be "commandeered" from such of their present owners, whether public bodies or individuals, as are weak enough to give them up at official instigation. In addition, there is to be a public garden (which is not in the least wanted) and an ornamental pedestal for the existing statue of the Queen. The result will be that Calcutta will be endowed with a large purposeless building, visited by a few European loafers and coolies. There is no reason to believe that as a work of art it will be much more successful than the average British attempts in this direction. In other words, it will be architecturally contemptible, an absurdity and incongruity in the Gothic-Saracenic or other bastard style. Calcutta, though it is the seat of government for four months in the year, is not visited by well-advised travellers except for social and business purposes. Its own residents do not care about the proposal, and grudge the space to be taken away from their great breathing ground, the Maidán. Anyone acquainted with India will know that in a question of this sort the only safe line is the utilitarian one; and some philanthropic work would be the best memorial, such as new hospitals.

THE TRAINING OF THE YOUNG ENGINEER.

Mr. MAW'S SOUND ADVICE.

IN the course of his presidential address before the Institution of Mechanical Engineers, on April 19th, Mr. William H. Maw spoke of the technical training which it is desirable should be given to our young mechanical engineers. He

I am particularly desirous that any criticisms which I may make bearing on the methods of teaching adopted at our technical colleges should not be interpreted as indicating any doubt whatever on my part with regard to the great usefulness and general efficiency of such institutions. On the contrary, I have the highest respect for the excellent work they are doing, and I regard them as absolutely essential to the proper training of our rising generation of engineers. But technical colleges are institutions of comparatively recent growth in this country, and I think that no one who has studied their methods would claim that they have even approximately reached perfection. Nor is it reasonable to suppose that such an end could have been attained.

To use a railway metaphor, the technical college may be regarded as a kind of cross-over road, diverting the student from the line of scholastic training to that of independent thought and action, on which he will have to make his way in the battle of life.

Useless Learning.

Nothing is more disheartening to a student than to find at some stage in his career that he has been devoting time to learning things which are not only useless to him, but which it is really desirable that he should un-learn; while, on the other hand, he has failed to acquire knowledge of which he stands badly in need. Yet this is a far too frequent experience with boys entering technical colleges from our public schools. Matters are, I am glad to say, improving in this respect, and many of our large schools are conducted on less hard-and-fast lines than formerly, and are thus materially aiding the technical colleges in the early stages of their work. The changes, however, which have so far been made in this direction are of a very limited extent compared with those really required, and there is still left to be done at the technical college much educational work which ought to have been done at school, the result being a waste of valuable time. This matter is one which merits the most careful attention of all interested in technical education.

Specialising.

At present the practice in most of our colleges tends to effectively introduce students to a very limited number of the branches of mechanical engineering; the consequence being that young men flock into departments of the profession already crowded, or, if they enter less popular branches, find themselves to a great extent without that special preparation for their career which it should have been the object of their college life to supply.

No one is more opposed than I am to the too-early specialising of a young engineer's training. To specialise too early means, generally, a narrowing of the field of view which is most detrimental to future success. Moreover, it is not until the engineering student has made substantial progress in his studies that he is really in a position to determine for which branch of his profession his predilections, his ability, or his opportunities best fit him.

But there comes a time when every engineer must specialise, if he really wants to attain anything more than a subordinate position; and my view is that this specialisation had better be at least commenced during the college career rather than subsequently—the student devoting the latter part of his course at college to the acquirement of a knowledge of the special principles which underlie practice in the particular branch of his profession to which he is about to devote himself.

The Study of Constructive Detail.

A point to which the attention of engineering students should be very specially directed during the later portion of their college training is the necessity for the careful study of constructive detail. Perfection of detail is the very essence of successful mechanical engineering practice; and to the careful observer, the study of a boiler which is being broken up, or of an engine or machine which is being stripped for repair, will afford an endless number of lessons of the greatest practical value.

SOCIETY OF ARCHITECTS.

ANNUAL DINNER.

THE annual dinner of the Society of Architects was held at the Prince's Restaurant, Piccadilly, W., on Wednesday evening last, Mr. T. W. L. Emden, L.C.C., presiding.

After the toast of "The King, the Queen, T.R.H. the Duke and Duchess of Cornwall and York, and the Royal Family" had been given, Mr. Silvanus Trevail, J.P., F.R.I.B.A., rose to propose "The Houses of Parliament." In the course of his speech he referred to the question of architectural registration. They looked to the members of Parliament present to help forward this measure with all their might, for it was imperative that architects should be registered. It was so in the Colonies, in America, in Germany, and it should be so here. Mr. E. Goulding, M.P., replied.

The next toast on the list was that of "The Clergy." In proposing this Mr. Edward Terry was most happy. He did not quite know, however, why he had been so honoured—perhaps they thought that, as an actor, he had a grievance against the clergy—he might say a number of nasty things about them. The clergy, however, were his very good friends. He himself had even been a churchwarden; but this was in a play he had translated from the German!—The Venerable Archdeacon Sinclair, D.D., replied. He thought it would be very helpful to clergymen if architects explained their plans to them; this would avoid much misunderstanding. With regard to London, he felt there was not much encouragement for the architect in modern church-building, because it was so necessary to erect churches which, whilst being large, were to be cheap; but special attention needed to be devoted to architectural acoustics, exits and outlets, ventilation and lighting—after the Oxford Movement the last-named seemed to have been considered an improper element in churches! He asked for the sympathetic criticism of architects in regard to the decorations now proceeding at St. Paul's Cathedral. The golden gallery was gradually creeping around the building, though it was entirely out of harmony with Wren's motives; and he did not approve the painting of the stonework, which possessed itself a charming surface. In conclusion, he much regretted that commercial requirements should so dominate architecture, and mentioned Edinburgh as an example where—not on account of its site, but because of the care of its architects and the municipal authorities—every street had been given a beautiful aspect.—The Rev. Dean Langton George Vere also replied to this toast. Baalbus, he said, was building a wall. But in the Latin *murus* meant not only the wall of a city, but the wall of a house. Baalbus continued to build this wall—he was always building it—and the speaker felt that Baalbus must have been a very great architect. He would be glad to know of any posthumous works of Baalbus! The clergy and the architects were alike in many respects; for instance, they were both designers—the clergy were often called designing men—and they both had to put up and to pull down.

"The London Authorities" was the next toast on the list. Mr. H. S. Samuel, M.P., proposed it, and Mr. E. A. Cornwall, J.P., L.C.C., replied. Mr. Cornwall referred to the fact that the London authorities had been reduced in number from 42 to 28, which must make the work of architects easier. He thought the London Building Act, with all its faults, had proved very workable, and considered it was to the credit of the London County Council that they had the welfare of architecture so much at heart; £80,000 could be saved if the church of St. Mary-le-Strand were removed, but the Council ruled otherwise.—Mr. J. Hunt (Town Clerk of Westminster), who also replied, said that the London Government Act had really reduced the 78 vestries and 12 district boards to 28 local authorities, with only 28 sets of officers; and had substituted 1,360 councillors and 250 aldermen for 4,000 vestrymen and 600 members of district boards.

The next toast, "Prosperity to the Society of Architects and Architecture," was proposed by Sir Wyke Bayliss, F.S.A., in a very poetical speech. He thought one of the greatest pleasures to the artist in London—in which term he included the architect—was that afforded by the meeting together of the great societies. They reminded one of the old guilds of Venice, Florence and Rome. All artists had one common aim—the pursuit of beauty; and in this connection he referred to the story of the castle said to be haunted by the spirit of the lady who was formerly its mistress. The children saw her, and said, "She is like us"; her lover saw her, and felt the same impression; and the old men saw her, and said that she was like what the Madonna must have been when she had grown a little old. Phidias had seen the spirit, and there was a Parthenon; Raphael, and we had a Madonna; Turner, and there was the "Fighting Téméraire" being tugged to her last berth; and it was because architects were looking at this vision that he proposed their health.—Mr. Emden replied. He said the work of their society was twofold—first, to enforce registration, and, secondly, for the encouragement of the art of architecture. Referring to the Queen Victoria Memorial, he expressed the opinion that the competition should have been thrown entirely open. The selected men were well known, but others should be given a chance, even though this might entail extra work on the Committee in having to make a choice from a great number of designs. He thought a great misunderstanding arose about "styles" of architecture. Men got wedded to one particular style, and could see no good in any other. This, he felt, was a great pity, especially in London, which owed so much of its picturesqueness to the variety of treatment in its buildings.

A pleasant evening was brought to a close by the toast of "The Visitors," proposed by Mr. W. W. Thomas (vice-president) and responded to by Mr. W. J. Bull, M.P.

A WORD FOR THE JERRY-BUILDERS.

By A DOCTOR.

SPEAKING recently at the annual meeting in connection with the Crownhill Convalescent Home, Dr. C. A. Hingston asked why was it convalescent homes had become such a necessity during the past thirty years? In the early part of the century England, with the exception of London, was wholly rural. There was no crowding into towns. The towns were more like villages, there was plenty of fresh air everywhere, and the population was scattered all over England. From about the date of the Reform Bill people began to crowd into the towns, and that had been going on steadily, not only by the increased population of the towns, but the country districts had been steadily denuded of their inhabitants. It had become a very grave question how to deal with that population which was crowding in increasing numbers into their towns. They heard of the building of houses for the working classes. He had had some experience of it, but he said it was impossible at the present rate to build houses for the working classes and build them well for a return of more than 2½ per cent.

They had heard the jerry-builders extremely abused, but he thought those builders were great public benefactors. Were it not for them he did not know how the population could possibly be housed. The jerry-builders had another great advantage. The houses were so badly built, and so cheaply run up, that they could afford to let them at rentals which well-built houses could not be let at. He was not quite sure that a poor building was not advantageous in other ways. When doors did not fit closely and windows were badly made, repairs were constantly needed, and they got good ventilation. He thought the jerry-builders were benefactors, certainly in the case of their town and their neighbourhood—(laughter and "How about the drains?"). The Sanitary Authorities of the towns were bound to see that the drains were right, and he supposed they did their duty, and that the houses were well drained. Far from cursing those builders they ought to bless them. What would London do without them? The population of London would be helpless were it not for the jerry-builders.

QUEEN VICTORIA MEMORIAL.

SPECIAL MEETING OF THE R.I.B.A.

ON the written requisition of twelve subscribing members, a special general meeting of the Royal Institute of British Architects was held on Monday evening last to consider the matter of the Queen Victoria Memorial. Mr. E. A. Gruning (vice-president) occupied the chair.

The secretary read a letter from the president (Mr. William Emerson) in which he stated that when the two committees—Lord Salisbury's Committee and the Executive Committee—discussed this matter three points came before them. The first, as to whether an architect of eminence should be selected to prepare designs; the second, as to whether there should be an open competition; and the third, as to whether a few men should be selected to prepare designs and be remunerated for their trouble. The Committee, after discussion, had adopted the last course.

A letter was then read from Mr. J. Macvicar Anderson in which he entered a strong protest against the object for which this meeting had been convened. It was a matter of opinion what might have been the best course to adopt, but this was not the point of his protest. If the nation desired that it be left open to all to submit suggestions, let this be expressed through the nation's representatives or the Press. He felt that the very last body to deal with it was the Institute, for this would be tantamount to asking that those of its members who had not been invited to submit designs should be permitted to do so, and anything more undignified or unprofessional he could not conceive.

At request two other letters were read expressing opposite views, one from Mr. Philip A. Robson.

Mr. Woodward's Resolutions.

Mr. William Woodward then rose to submit the resolutions he had prepared, but before doing so he thanked the Council of the Institute for allowing them to meet at the earliest opportunity. His resolutions, which, however, were only put forward as tentative, were as follows :—

1. That in the opinion of this meeting the proposed National Memorial to Queen Victoria should be open to the competition of all British—including of course Colonial—architects, sculptors and artists.
2. That the first designs should be in the hands of the committee at the date already fixed, namely, the end of June next—and that from those designs six should be selected, the authors of which should be engaged to perfect their schemes, and submit them at a date to be decided upon by the committee.
3. That the author of the design selected from the six should be employed to carry out the work in collaboration with the sculptor or sculptors whom the committee may designate.
4. That in the event of the Memorial being thrown open to general competition, as above suggested, the information furnished to the five architects already appointed, for their guidance in the designs, be immediately made public.
5. That the whole of the preliminary designs, as well as the subsequent perfected designs, be publicly exhibited.
6. That these resolutions be at once transmitted to the Viscount Esher with a request that they be laid before His Majesty the King.

Referring to the letters read by the secretary, he said with regard to Mr. Macvicar Anderson's that such opinions were only to be expected from one who had attained the position of having arrived at the end of a very fine career; for he (Mr. Anderson) would view any efforts on the part of the younger generation as unconservative. That feeling, however, did not dominate his breast, nor, he thought, the breasts of many there that evening. They were desirous of showing that art in this country was not on the ebb, but on the flow; and among the younger men there must be great talent only awaiting opportunities like that of this memorial. If the Press were ever unanimous on any subject, it was this one. Even the "Times," in an inspired—though very fair—leading article, while deprecating the open competition, said that the nation desired this one to be so conducted.

The funds for the memorial were public funds, and it was only natural that the public who subscribed them should wish to have some share in deciding what use they should be put to; and the public had said that the competition should be open.

There was a general committee and a sub-committee appointed to deal with this matter, the president of the Institute being among the members of the latter. But the president gave them no information as to what had taken place, and no efforts had been made to ascertain what the opinions of the Institute were.

The chairman here remarked that the president, as a member of the committee, could not make public what had transpired.

Continuing, Mr. Woodward said with regard to the five architects chosen, that it was impossible for any of them to know more than any other five architects about the particular character of this memorial. If it had been a cathedral or an asylum, or a hospital, for which work five architects had proved themselves to be specially suited, it would have been different; but in this country no one architect, and certainly not five, had had an opportunity for an exhibition of the qualities needed in this particular design.

It had been said that open competitions involved a great deal of trouble. He was not so sure, however, that the committee would be overrun with designs, and, even if they were, it would be an easy matter to separate those which were of worth from those which showed no merit. As the results of open competitions he mentioned the Paris Opera House and our own Houses of Parliament, which we never otherwise would have had. Therefore he contended that, in order to get the very best talent available for this memorial, the competition should be open.

Professor Beresford Pite said he was heartily in sympathy with Mr. Woodward's remarks, but did not think it quite advisable to put forward the resolutions in the manner suggested. He would therefore propose an amendment.

The chairman pointed out that Mr. Woodward's resolutions had not been seconded. A member therefore seconded them, and in doing so expressed the opinion that it was a pity the Institute had not itself called a meeting of its members to discuss the matter. The majority of them had been taken completely by surprise. The country seemed taken by surprise, for the scheme had been greatly hurried, and very little was known about what had taken place.

Mr. Pite's Amendment.

Mr. Pite then moved his amendment, which was as follows: "That considering the deep and widespread interest manifested throughout the Empire in the proposed National Memorial to Her late lamented Majesty Queen Victoria, and in view of the limited opportunities for the exercise of monumental design in London that have been offered during recent years, and the absence of useful precedent, this special general meeting of the Royal Institute of British Architects, of which Her late lamented Majesty was patron throughout her long reign, respectfully urges upon the Executive Committee of the National Memorial its earnest conviction that designs should be invited in open competition from all British architects for this most important and unique monument, which it hopes would thus become representative of the best and most enthusiastic efforts of modern monumental architectural art; and further this meeting would suggest to the Executive Committee the necessity of affording sufficient time for the preparation and submission of designs by architects resident in all parts of the Empire, of whom many are members of this Royal Institute."

Referring to the president, he said he was sure he had done everything he possibly could in the interests of the profession; and he was of course perfectly right in not revealing what had transpired privately in the committee of which he was a member. At the same time he thought it was quite justifiable for them to discuss the matter. If a mistake had been made surely it ought to be rectified. A certain dean and chapter of one of our finest cathedrals invited an artist to spoil it—officially; but that was no reason why a protest should not be made. He felt the committee's mistake had been one of judgment, not one of form or manner.

With regard to competitions as a whole, he thought it should be borne in mind that it was their abuse that was objected to; and if there was no abuse there would be no use; but the abuse was not to blind our eyes to the fact that they also had a use. He referred to the enormous waste of money caused by competitions, but in this case that question was not concerned. He mentioned to the competition which [illegible] produced the only fine monument of our era—the Wellington Monument in St. Paul's Cathedral, by Alfred Stevens. The finest monuments the world has ever seen in all ages, he said, had been attributable to open competitions, and he did not think they ought to be stamped out now because they were subjected to abuse in small particulars.

Mr. H. V. Lanchester had great pleasure in seconding Mr. Pite's amendment. He said they were quite within their rights in discussing this matter, for every chance should be taken in order to secure the very best they could obtain.

Mr. Wimperis thanked Mr. Woodward for bringing them together that evening, but thought they should try to deal with the matter without personalities. The five architects selected had done much for architecture, and had helped to found a school which the younger men would establish in due time. But other names occurred to them which should be included. So eminent an architect as Mr. Norman Shaw had expressed the opinion that this competition should be entirely open, and he did not think any body of architects could afford to ignore such an opinion.

Mr. Frampton thought they had treated the Colonies badly. In matters national we were going backwards—back as a nation, and back in our arts. He asked for the "free trade" in Art that characterised the Paris methods; if there was a difficulty about assessors, why not have juries? But he was ruled out of order by the chairman.

Mr. Maurice B. Adams agreed with the remarks of Mr. Pite, but felt that a great mistake would be made if they carried the resolution. It was no use hitting unless you could hit hard. Their president was a member of the Committee, and he was perfectly certain Mr. Emerson had done his utmost. He cautioned them to think carefully over what they did, for they might do more harm than good.

Mr. Woodward said he was quite willing to adopt Mr. Pite's amendment, as his only object was to obtain an open competition. Therefore, he begged leave to withdraw his resolution in favour of Mr. Pite's.

Mr. Silvanus Trevail said that they had good men in Canada and Australia, and it would be a great slight, considering how the Colonies had come forward over the South African War, to pass these over. He would not mind even if the competition were made open to the whole world.

Mr. Douglass Mathews, Mr. Lishman, Mr. Bonner, Mr. Tanner and Mr. Hudson then spoke, after which the amendment was put to the meeting and carried unanimously. By far the majority of those present were of opinion that matters had been kept too secret, and that, in the interest of architecture, the competition should be an open one.

Glasgow Municipal Buildings.—The decoration of the Banqueting Hall of the Glasgow Municipal Buildings has now been completed; the four panels painted by Messrs. John Lavery, Roche, George Henry, and A. E. Walton being unveiled recently.

Strengthening Balmoral Bridge.—His Majesty the King has given orders for the improving and strengthening of Balmoral Bridge, which during this month will be closed for the purpose, and his Majesty has commissioned Sir William Arrol in connection with the work. The contract for the improvement of the roadway over the bridge has been given to Messrs. John M'Adam & Sons, contractors, Aberdeen. The bridge will be laid with tar-macadam.

The New Baths and Free Library at Oadby, presented by Mr. G. H. Ellis, have been opened. The building is situated on the Leicester Road, and is built of red brick. The baths are placed at the back of the building, and entrance to them is gained through the front porch. The bath is 51ft. long and 24ft. wide, and the depth ranges from 5ft. 6in. to 3ft. 6in. White glazed bricks are used to line the bath. There are four slipper baths, two on each side of the entrance, and near them are the usual conveniences and the attendants' rooms. The library is placed upstairs, and the reading room, which is intended for women only, is a very light and well-ventilated apartment about 17ft. square.

SIR JOHN SIBBALD ON ASYLUM CONSTRUCTION.

AT a meeting of the Edinburgh Architectural Association last week—Mr. Henry F. Kerr presiding—Sir John Sibbald read a paper on the plans of asylums for the insane poor, looked at from the medical and administrative points of view. He said that asylums for the insane had now become so prominent among our national and municipal institutions that it was of great public importance that correct views should be held as to the kind of building which was best suited for them. It was at least helpful, if not absolutely necessary, for a proper understanding of such questions, to know something of the ground on which persons familiar with the treatment of the insane had arrived at their present opinions; and this knowledge could be best obtained by taking a general survey of the changes that had occurred in the character of asylum buildings during what might be called the modern epoch.

Sir John briefly referred to the kind of buildings in which the insane were lodged previous to the nineteenth century, and mentioned as illustrations the cells attached to the Charity Workhouse and the old Royal Infirmary, Glasgow. The duty of erecting asylums at the public expense was not seriously recognised in this country till the middle of last century, when the English Lunacy Act of 1845 and the Scottish Lunacy Act of 1857 laid this duty upon localities, and conferred on them powers for obtaining the necessary funds.

To illustrate the growth of opinion in regard to asylums since that time, Sir John first referred to the plans of the Derby County Asylum, which was opened in 1851. He then drew attention to the plans of the London County Asylum at Bexley, which was opened in 1898, and referred to the improvements which showed themselves in the more recent plan. Among these it was noticed that the several wards into which the accommodation for patients is divided no longer consist, as they did at Derby, of rows of cells in prison-like galleries, identical in plan, but that they are each specially designed for the patients they are to accommodate, according to the requirements of their different bodily and mental conditions—those requiring hospital treatment, for example, being placed in wards arranged like those of a hospital, and those in good bodily health, and whose mental condition does not require them to be housed differently from sane persons, being placed in wards of more home-like character.

He pointed out that this type of asylum, which he called the aggregated pavilion type, differed from the next type to which he drew attention, chiefly by the several wards being connected to other wards either by being portions of the same building or by the existence of corridors of communication. The type in which the wards consist of separate and independent buildings he called the segregated pavilion or village type; and he illustrated it by reference to the plans of the Prussian asylum at Alt-Scherbitz and of other more recently erected asylums of the same type. He gave a number of reasons which, in his opinion, justified a preference for the segregated pavilion or village type. Among these he mentioned the importance of making the buildings, and everything else about an asylum, as likely as possible to have a beneficial influence on the minds of the patients; and he showed that it was difficult to prevent a huge building which was neither a palace nor a manufactory from being both inside and outside gloomy and prison-like. He was also of opinion that where each ward was a completely independent building its arrangement could be made more efficient both from the general points of view of cheerfulness and health and from the special point of view of the adaptation of each ward to its own purposes.

He said that he thought the objections to the segregated buildings that had been raised from the administrative point of view were sufficiently met by the fact that they received no support from those who have had the actual administration of a village asylum. He alluded to the fact that it was proposed to erect the new Edinburgh Asylum on the village type, but did not make special reference to the Bangour plans, as they had not yet been finally adopted by the District Lunacy Board or approved by the General Lunacy Board.

In the course of the paper Sir John drew attention to the difference in practice north and south of the Tweed in regard to the courts surrounded by high walls which were at one time attached to asylums as well as prisons, and which are generally known as airing courts. He said that in Scotland the use of these airing courts had fallen into disfavour as early as 1869, and in that year the walls were removed and the airing courts abolished in one asylum. Since then the walls had either been removed, or lowered so much as to cease to be restrictive, in nearly every Scottish asylum; and in no Scottish asylum erected since 1869 had any airing courts been provided. In English asylums, on the contrary, airing courts were still in general use, and he quoted from the English Commissioners' reports to show that in at least three of the London County Asylums from one-fourth to one-third of the inmates never took exercise beyond the airing courts. He strongly advocated the abolition of these airing courts. Another point to which he drew attention was a recent movement—to which he gave his support—for the diminution of the practice of locking up in single rooms during night-time the noisy, the excited, and others of the more troublesome patients; and he spoke strongly in favour of the great increase in recent years both in the amount and the efficiency of the night-nursing given to such patients, and he showed how such a change in the mode of treating them should affect the plans of future asylums.

ARCHITECTURE AT THE ROYAL GLASGOW INSTITUTE.

THE exhibition of architectural drawings at the Royal Glasgow Institute this year is by no means of first importance as regards amount or quality. The frames number about fifty, and, with the exception of a dozen or so, all are of work erected or in progress: the remainder are drawings of old work, decorations or glass. The medium for illustration in most cases is pen work, but colour and wash drawings are also in evidence, and there are several photographs. "In accepting these the Glasgow Institute is wiser than the academies that exclude them," says the "Glasgow Herald," "for in many cases the camera gives the most faithful representation; of course, work not yet erected can only be shown by drawings. While principally from local sources, there are several contributions from English architects."

Churches.

Of local architecture in progress or recently finished, taking first ecclesiastical, of nine examples eight are Gothic, one only being Renaissance; and this proportion is not accidental, but may fairly be said to reflect the popular taste of architects and laity alike, who accept the traditional association without demur. The exception is the parish church at Lesmahagow (701) that Mr. A. N. Paterson has remodelled, adding a chancel, the furniture of which is particularly interesting.

Among the other church designs shown are "St. Kennett's" (697), by Mr. P. M. Chambers; Shawlands U.F. Church (700–760), by Messrs. Miller & Black; Sherbrooke Church (724–748), by Mr. William F. M'Gibbon; U.F. Church at Milngavie (703), by John B. Wilson; and a church by Mr. Quennell (746), the only English example shown.

Public Buildings.

Of public buildings, the new Parish Council Offices in George Street, Glasgow (717), by Messrs. Thomson & Sandilands, are the most important locally. Cardiff Assize Court Entrance (730), by Messrs. Lancaster, Stewart & Rickards, is in the Classic style, but a touch of originality is given here in the treatment of the entablature and in the use of rustication. Plumstead Municipal Offices (735), by Messrs. Wimperis & East, are also in the Classic, freely treated. A bank at Bromley (710), by Mr. Ernest Newton, possesses all the interest that this architect gives to every one of his works. Another example of Mr. Newton's skill is a garden entrance (713), very nicely detailed. 715–716 are photographs of part of the new Porte Buildings, Burntisland, by Swanston & Legge—a sundial is shown with this inscription: "I mark time; dost thou?"

Unsuccessful competition designs are frequently not the least interesting drawings in these exhibitions; but this year they are not so numerous as usual. Messrs. Watson & Mitchell's Glasgow Royal Infirmary (727 and 744) is the Jubilee block that was proposed to replace the present one by Adam, facing the square. Mr. Burnet's scheme for the National Bank at the corner of Buchanan and St. Vincent Streets (728) differs from the accepted one in the entrance being placed at the corner in a tower that terminates with a dome.

Domestic Work.

Of domestic architecture the largest local example is the house at Kelvinside (723), by Mr. H. E. Clifford. The style is English Renaissance, with open porch, stone terrace, and large flat oriels, all very solidly treated in stone. Something of the same treatment is seen in the house at Perth, by Messrs. Watson & Salmond (746); quiet and well proportioned, the large windows that give the whole character to the exterior are just of the kind that makes a room beautiful within. From the same hands is the steading (751) at Netherton. 704 and 755 are country houses by Mr. Macartney, both of brick. Frithwood House has projecting eaves in the form of a cornice; Welders runs up to a parapet and ogeed gables. 749 and 757 are views of "The Retreat," Lakenheath, by Mr. Andrew N. Prentice, a fairly large country house that has considerable variety of material in its construction, but none more noticeable than the thatching, shown worked into a kind of pattern. Photographs 731 and 732 are houses by Mr. Lutyens, known locally for his inn at Rosneath, of great interest. Perhaps the best example of the small brick house shown is that at Walton-on-Thames (741), by Messrs. Niven & Wigglesworth, whose ogeed gable and three oriels, alike and carried up two floors, show simple treatment and studied design in the symmetry employed and the proportions of best conventionality. Half-timbered work is almost absent from all the English examples shown.

Interiors and Old Work.

Of interiors, by far the most elaborate is the yacht "Margarita" (705), by Messrs. Watson & Mitchell. Photographs show a profusion of richest detail that would be oppressive anywhere else than in a ship where the nearness of every part to the eye-level and the concentration of attention given to every little detail in one's circumscribed home is sufficient justification.

Among the drawings of old work, the best is the Banqueting Hall of Craigievar Castle (699), by Mr. James Smith. 694 and 750 are good pencil-drawings of a font in Sienna Cathedral and a doorway in St. Mark's, by Mr. L. R. Guthrie. 729 is a decorated ceiling from Pistoja, by Mr. John Stewart. Mr. Pennell's pen drawings of Notre Dame of course stand in no need of praise.

The Exhibition stand (753), in Saracenic style, by Messrs. Honeyman & Keppie, is very bright and suitable in design. An interesting feature in the room is the presence of cases of jewellery by Mr. Gilbert, R.A., and silver objects by Mr. Gilbert Marks.

This sums up the Architectural Section. The average of merit is more than respectable, and there is no very poor drawing hung. All the same, the absence of worthy contributions from architects of note is conspicuous, and this may account for the leniency of hangers, who have accepted some works that hardly call for public exhibition.

A Foreign Competition.—The Florentines recently threw open to public competition the designing of the facade of St. Lorenzo. Like most of the Florentine churches, it has hitherto been without a facade. A large sum of money having been left for the purpose of completing the church, a circular was sent to all the art schools and well-known artists in the country. A thousand drawings were sent in, of which fifty-two were selected for further consideration by a committee of seventy-two competent judges. It seems that the design which has received the greatest amount of votes is the work of a hitherto unknown and very youthful artist.

THE CLASSIFICATION OF ROMANESQUE ARCHITECTURE.

BY FRANCIS BOND, M.A.

THE following is an abstract of a paper read before the Royal Institute of British Architects on April 22nd last by Mr. Francis Bond, M.A.

In introducing his subject Mr. Bond alluded to some of the difficulties which beset the student on his first introduction to the great style which preceded Gothic and was based on Roman work. This subject of the classification of the Romanesque styles was a large one, and could only be dealt with shortly within the limits of his paper. Classifications already existed—those of De Caumont, Quicherat, Viollet-le-Duc, and particularly Anthyme Saint-Paul, were referred to—but they helped one but little forward. It remained to consider whether a wider basis of classification could not be found—one resting on the main facts of plan and structure.

The Efforts of the Old Builders.

First of all, what was the one thing that the old builders—whatever the schools they belonged to—were trying to do? With the exception of a certain number of them who were attempting to solve the church-building problem by following the type of St. Stefano Rotondo at Rome or of St. Vitale at Ravenna, and whose furthest outposts, with the exception of the churches of the Knights Templars and the Knights Hospitallers, are to be found in the churches of Aix-la-Chapelle, Ottmarsheim, and Germigny-des-Prés, all the builders of Western Europe, from the ninth century, when Romanesque architecture commenced, to the twelfth century, when it was superseded by Gothic, were engrossed with one supreme problem—how to vault a basilica. This was the master problem of the builders of the Middle Ages from the end of the ninth to the middle of the twelfth century. The amount of engineering skill, the ingenuity, and the variety of the solutions proposed were astonishing. They seemed never to have had their full due. Gothic architecture got nearly all the credit. As a matter of fact, every single one of the main difficulties inherent in the task had been effectually met—and met in more than one way—before the first Gothic architect ever handled a trowel. Early in the twelfth century, or before, at least five complete solutions had been arrived at, as may be seen at Le Puy, Tournus, Cluny, Speyer, and Durham.

Vaulting Classified.

The problem how to vault a basilica meant —(1) that there were to be aisles as well as a high nave; (2) that some form of vault construction was to be devised; (3) that since a vault of stone was heavy, piers must be substituted for graceful, but weak, classical columns; (4) that the thrusts of the high vault of the nave must be stopped in some way by abutment in or above the aisles; (5) that top-lighting by clearstory windows was to be retained; (6) that the outer surface of the vault must be protected from the weather.

(i.) In most cases one or more of these conditions were evaded. One school—the most ancient of all, which held the whole of the field till the ninth century—simplified the problem by omitting the vault and retaining the colonnade.

(ii.) A second solution—also very incomplete —was to omit the aisles; to build a hall-church roofed with a tunnel vault. This simplified the question of supports, for it substituted solid walls for hollow arches, any amount of clearstory light could be introduced, and the walls could be thickened to any extent to provide continuous abutment to the thrust of the great tunnel vault. Everywhere it was the natural and proper solution where only a small church was required, but it was employed in Provence even in churches of cathedral rank.

(iii.) A third method, represented by the school of Périgueux, also removes the difficulties of supports, abutment and top-lighting by eliminating the aisles. It presents us with another variety of hall-church, roofed, not with a tunnel, but a row of domes, and it is to be noted that the corners of each square bay of the nave are filled in with pendentives to support the dome.

(iv.) The next method is found only in the church of Loches, near Tours. Originally there was a low tunnel-vaulted nave, without aisles, of the eleventh century. But about 1160 the eastern portions of the nave were pulled down, two square bays were formed, and on these bays two spires were erected.

(v.) In two churches of the first rank a row of domes was employed to roof an aisled nave. The nave was spanned by a series of strong arches. These were so placed as to divide the nave into square compartments. On each square an octagonal dome was poised, the corners of the square being filled up with corbelling or squinches to afford support all round to the base of the dome. The typical example of this is the wonderful cathedral of Le Puy, the nave of which is roofed by a row of six domes on squinches.

(vi.) The next method may be distinguished as the arch-and-lintel system. Strong transverse arches were built across the nave about 9ft. apart; a wall was built on each arch rising up to the apex of the arch, and then lintels of basalt were laid longitudinally—*i.e.*, from west to east. Count Vogüé has fully illustrated this curious phase of architectural history in "La Syrie Centrale."

(vii.) We next come to a whole series of attempts to solve the problem by covering an aisled nave with what is called a tunnel, wagon, barrel or cradle-vault. Of these the most scientific is that of Tournus Abbey church. As in the churches of Syria, the nave was spanned by stout arches, each arch carrying a wall. But each pair of these walls, instead of carrying lintels, as in Syria, carries a short tunnel set *transversly*.

(viii.) We now come to the vast number of churches in which the tunnel-vault of the nave was placed longitudinally—*i.e.*, in the direction of the axis of the church. The naves vaulted with longitudinal tunnels may be divided into those (*a*) where the tunnel rests on a pier-arcade; (*b*) where the tunnel rests on the arches of an upper vaulted aisle; (*c*) where the tunnel rests on a wall pierced with clearstory windows.

(ix.) Such interiors as that of Notre-Dame de Poitiers were painfully low. It would have been dangerous, however, to raise the tunnel much by increasing the height of the piers. So, in Auvergne especially, the expedient was hit upon of building two aisles instead of one, both vaulted; then the tunnel could spring at a much higher level. Moreover, some of the gloom of the Poitevin type of nave could be dispelled by piercing the back wall of the new upper aisle with windows.

(x.) The first step to carry out the one unfulfilled condition in the problem—the provision of clearstory light—was taken by piercing the base of the tunnel itself with clearstory windows. The final step—a most important change—was to insert the windows wholly in a clearstory wall. This latter seems to have been accomplished independently in the south, in Provence and Languedoc; in the north, in Burgundy. The clearstory was already in use in tunnel-vaulted churches in the eleventh century at Saint-Guilhelm-du-Désert, in the Southern Cevennes; and in Burgundy on a small scale at Saint-Benoît-sur-Loire (commenced 1062), and on a gigantic scale at Cluny (commenced 1089).

(xi.) This solution, which was destined, within a generation or two, to culminate in the Gothic architecture of Saint-Denis (1140), consists in covering a nave with unribbed groined vaults.

(xii.) The final step was to substitute the ribbed for the groined vault, to dispose the vaulting compartments of the nave in oblongs, to facilitate the vaulting of these oblongs by the application of the pointed arch, and to transmit the thrusts of the high vault by means of flying buttresses to the buttresses of the aisle walls. To this, Gothic architecture added three developments: (1) It weighted the buttresses with pinnacles; (2) to a large extent it replaced the masonry of the walls by glass; (3) in Durham nave, the Abbaye-aux-Dames, and elsewhere, abutment was sometimes provided by flying buttresses disposed beneath the aisle roof. In Gothic the flying buttresses are placed above the aisle roof.

(xiii.) This method, which consisted in omitting the vault, was no solution at all. The nave is not constructed in genuine basilical fashion, as in the first method, but is built as if a vault were intended. The home of this unworthy construction is Normandy.

A Criterion.

Of the foregoing solutions of the vaulting problem, the third, the employment of a dome resting on pendentives, is by itself a full and satisfactory criterion. It occurs nowhere except in a group of some thirty-five churches in the district of Périgueux, with such "outliers" as Fontevrault and Angoulême. No. 2, the hall-church, is most common in the south-west and south of France, from Poitou to Provence. It may be vaulted either with a longitudinal tunnel or with groined or ribbed vaults. No. 8, where a tunnel vault rests directly on the pier arches, occupies much the same districts as No. 2. No. 9, where the tunnel rests on the arches of an upper aisle, extends from Clermont-Ferrand, in Auvergne, to the south-west as far as Conques and Toulouse. No. 10A, where the tunnel is combined with a triforium and clearstory, is the final development reached in Burgundy. No. 10B, where there is tunnel and clearstory, but no triforium, is the solution of Provence and of Piedmont. No. 12, the ribbed vault, occurs sporadically, except in Germany and Lombardy, where it is characteristic. No. 13, the unvaulted nave, was nearly universal in Normandy and England till the twelfth century was well advanced.

The Planning Test.

The author went on to consider how these eight divisions will stand other tests. A very important test is afforded by the planning of a church, especially of its eastern limb. It must suffice to trace four main types of choir-plan. The first is that with three parallel eastern apses, of which there is a variant with square-ended aisles, as at Cerisy-la-Forêt, and another with aisles square externally and semicircular internally, as at Romsey. This is pre-eminently the plan where the unvaulted nave prevails, viz., Normandy. It is frequent in Lombardy and in those Provençal churches that have aisles. A second plan is that of the ambulatory and "chevot." It is rare in Germany, Lombardy, and Provence, and non-existent in Normandy (excluding England).

The plans alone, apart from other considerations, would entitle Germany to rank as a distinct architectural province. In Provence the aisled churches generally have three parallel eastern apses.

The Central Tower Test.

The divisions may be tested again by the treatment of the central tower: (1) its vaulting; (2) its shape, whether square or octagonal.

The Romanesque builders had three forms of vault at their disposal in the eleventh century; the groined vault, the tunnel vault, and the dome. The most difficult problem they had to cope with in vaulting was the question of putting a vault over the crossing, resting not on walls, but on four unbuttressed legs. They had hardly dared yet to put a groined vault over their naves, fearing its concentrated thrusts. Their favourite tunnel vault could not be used at all at the crossing, for it needed solid walls for its support. They had perforce to use the dome, in all cases, except in the Périgueux district, resting on squinches. Secondly, they had to stop the thrusts of this dome by carrying up a central tower to weight the arches or walling on which the dome rested. As regards the shape of this tower, they had two alternatives. The crossing was square, and so the tower over it might be square, as was the great central tower of Cluny and that of Tournus. But the squinches reduced the square of the crossing to an octagon; and as the tower rested directly on the octagon and not on the square, it was more natural that the tower also should be octagonal. Hence that magnificent series of octagonal central towers in Burgundy and Southern France, Germany, and Lombardy, culminating at Mayence and Saint-Sernin, Toulouse. In Normandy and England, on the other hand, the builders hardly ever dared to vault their naves at that early date, and never the crossing. And there being no dome in an Anglo-Norman tower, it is square.

Grouping of Towers.

Another test is afforded by the grouping of the towers. (1) The glorification of the tower reaches its highest pitch in Germany. Six towers are found at Speyer, Worms and Laach, seven at Limburg. (2) In Burgundy the magnificent tower group of Cluny seems to have remained without a rival. Its daughter churches were satisfied with a triplet; an octagonal central tower and two square western towers was the favourite arrangement. The towers have several stages, similar in form. (3) In Normandy also the triplet was the favourite, but the central tower was square, and not domed internally. (4) In Poitou the characteristic is the conical spire "en pomme de pin," which often surmounts the tower. (5) In the Périgordian region is seen the same conical spire, together with the characteristic cupolas. (6) In Provence "a simple square tower is common, with a very low spire." But some have central octagons. (7) In Auvergne a specially characteristic arrangement is that of a square western tower in the centre of the facade and a central octagon. (8) In Northern Italy the campanile type greatly predominates, and where the massive Romanesque tower is found, it is usually divided (in campanile fashion) into very numerous stages. Nowhere, except in the Como churches, does the campanile form part of the structure of the church; often it is quite detached.

Summary.

We may discriminate the following eight schools of Romanesque: I., the Périgordian; II., the Poitevin; III., the Provençal; IV., the Auvergne; V., the Burgundian; VI., the Norman; VII., the German; VIII., the Lombardic.

As regards the above classification, one word of caution is necessary. In speaking, *e.g.*, of the style or school of Auvergne, it is not meant that all the churches in Auvergne were built in this style, or that there were no such churches outside Auvergne, but merely that such churches were more common in Auvergne than elsewhere, and may therefore for convenience be described as belonging to the style or school of Auvergne. Also that those features described as characteristic were not invariably found; they were merely those which occurred most frequently.

One is tempted to try to work out the relations to one another of the different schools. Certain resemblances are patent. The superimposed aisles link the style of Lombardy to that of Auvergne; German Romanesque is connected with Lombardic on the one hand, and with Norman on the other. But a much more exhaustive classification is necessary before any results of lasting value are likely to be obtained.

Still stronger is the temptation to enquire into

The Origins of all the Romanesque Styles,

whether they are derivatives, as some have held, from Provence or, as others have held, from Lombardy. Such architectural pedigrees are not, as a rule, trustworthy. And there always remains an alternative hypothesis, which seems to have within it much of truth, namely, that the styles were none of them mainly derivative, but that the same problem was engaging all the different regions more or less simultaneously; that the builders of each region were solving it, with some little light, indeed from their neighbours, but mainly independently, by empirical experiments of their own, aided by the survival here and there of traditions of Roman construction, and by the study of local Roman monuments.

Another caution requisite is that the classification does not cover the whole ground. This is necessarily so. Between each region and the next there was always a debatable ground, where two or more styles would be in simultaneous use. Indeed, a "pure" region would be the exception; the greater part of the area of any one country would employ mixtures of style. England is an instance.

It had always been customary, the author believed, to regard the Romanesque of England and Normandy as one. The Romanesque of Normandy, however, seemed to be a "pure" style, and that of England a "mixed" style. While by far the most important factor is the influence of such pre-Conquest churches as Bernay, Jumièges, and the Abbaye-aux-Hommes, we must also attribute some degree of importance, at any rate in the planning, to the highly developed Romanesque of Auvergne and Burgundy.

New Patents.

The following patents are open to opposition until June 3rd.

1900. — **Quick-setting Cements.** — 5,659. W. Wright, 48, Chesterton Road, North Kensington, W. Carbonate of potash or other suitable alkali is added to the water used in mixing the cement, making the latter set much more quickly. The proportion recommended is 1¼ oz. of the potash to one gallon of water.

Plaster Slabs.—6,338. E. v. Hedemann and R. v. Hedemann, both of Mariendalsoej 23, Copenhagen. Upright cruciform moulds are arranged on a carriage, and the moulding takes place on the site. Corner slabs can be moulded with one, two, or four corners, and by inserting loose end-pieces slabs of any proportion can be made. The slabs are smooth on both sides, and it is claimed that the work can be done quickly by inexperienced workmen. There is also the saving of the carriage on slabs between factory and building sites.

Surveying Instruments—6,819. M. Baumer, 7 & 8 Fenerweg, Nuremberg, Bavaria. The object of this invention is to enable surveying and plotting to be done without calculation. The instrument consists of a distance-meter, a system of rules, and a marking-point for determining the projection of the point sought and for reading off the catheti, and of a specially constructed theodolite. From the hypotenuse read off the corresponding catheti of even an inaccessible point can be directly obtained, and thus the co-ordinates also. Moreover, the result is transferred to paper on the spot and without the size of the projection being taken into account.

Sewage Tanks.—8,224. T. I. Goldie, Highbury House, Theatre Street, Norwich. Combined with one or two series of bacterial tanks is a single inspection chamber common to all. Another part of the invention relates to the syphonic discharge of sewage from one tank to another.

Conduits.—9,654. J. Hamblet, Piercy bluebrick, tile and pipe works, West Bromwich, and I. Parkes, 25, Bromford Lane, West Bromwich. Instead of moulding the sockets to receive electric cables separately and sticking them on to the body of the conduit, the socket is moulded in one piece with the conduit; this by the use of special dies.

The following specifications were published on Saturday last, and are open to opposition until June 11th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—194, Lancaster, apparatus for purifying acetylene gas. 5,843, Wright, bricks for building and decorative purposes. 6,295, Aldous & Aldous, ventilators. 7,824, Stanley & Smith, apparatus for forming the socketted ends of drain pipes. 8,094, Bickle, catch for doors and cupboards. 8,177, Gauntlett, Venetian blind. 8,484, Golby (*Woas*), flooring. 9,347, Pogson & Johnson, locks for windows, fanlights, &c. 9,361, Hilscher, levelling staffs. 10,218, Coiffier, Viéville & Majesté, manufacture of bricks, tiles, pipes, &c. 10 254, Crellin, lifting jacks. 13,750, Johnson (*Furness*), tiles for floors and other surfaces. 16,241, Clements, door-checking and holding apparatus. 22,540, Hight, street-sweeping machines. 22,596, Meurer, process for colouring glass yellow, red, brown, and black. 23,841, von Bischoff, draining apparatus for condensation water.

1901.—458, Davis, opal-glass facing tiles or plates. 667, Kling, buffers for street cars. 3,039, Calleson, drawing presses. 3,583, Mack, gypsum, cement, and similar slabs. 4,226, Harrass, manufacture of veneer structures. 4,307, Jamison & Martin, bolt fastening and tool for setting it. 4,502, Rowsell, taps, cocks and valves.

Sixty Workmen's Houses at Southend are to be erected by the Town Council at a cost of £16,250, including the purchase of land.

Do You Travel?

If so, you should not be without our

INSURANCE TICKETS.

There are **Three Schemes of Insurance** connected with our Papers, guaranteed by the Ocean Accident and Guarantee Corporation, Ltd. They are of the greatest importance to our Subscribers.

Scheme No. 1 is a free Accident Insurance of **£500.**

Scheme No. 2 is an Accident Insurance of **£500,** giving the following additional advantages:

£250 for Permanent Total Disablement.

£2 10s. 0d. per week for Temporary Total Disablement.

The premium for this Scheme is 1/-

Scheme No. 3 is an Accident Insurance of **£1,000,** with these additional advantages:

£500 for Permanent Total Disablement.

£6 per week for Temporary Total Disablement.

£1 10s. per week for Temporary Partial Disablement.

£30 Annuity.

£3 per week during confinement from such illnesses as Diabetes, Scarlet Fever, Carbuncle, &c., &c.

The Condition attached to these Schemes is that they only apply to Annual Subscribers to

Bricks and Mortar.

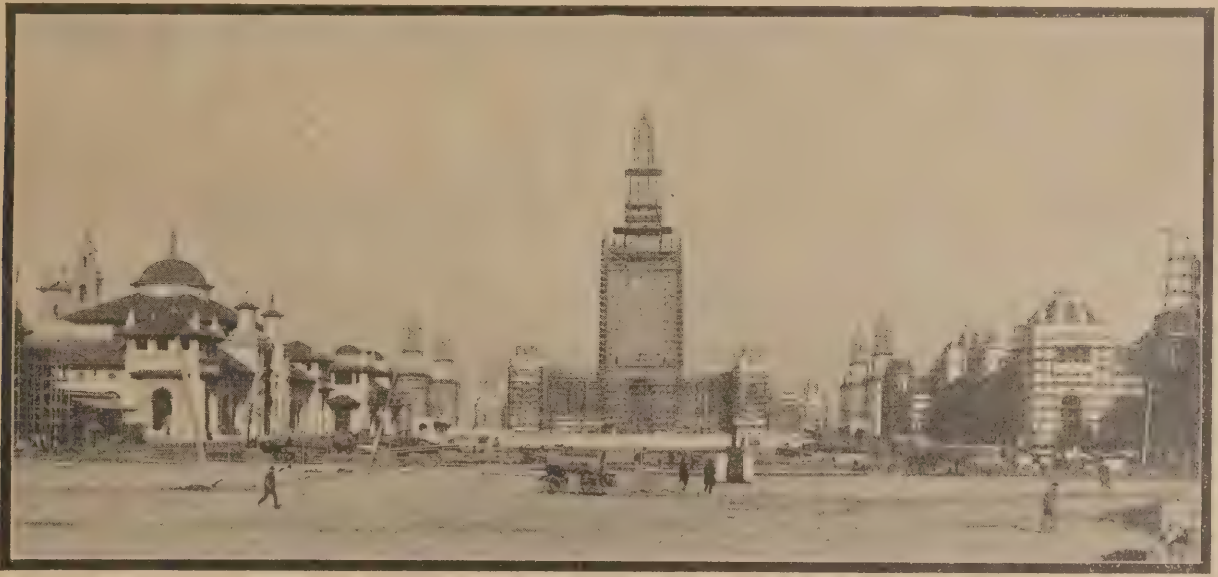
APHORISM FOR THE WEEK.

A taste for sculpture belongs to the best, purest and noblest of our enjoyments; and we feel most reluctant to be separated from those forms from which, however often we contemplate them, we derive renewed and indeed heightened pleasure.—HUMBOLDT.

Our Plates. "DICKHURST," near Haslemere, Surrey, by Mr. C. Harrison Townsend, F.R.I.B.A., is now in course of erection. Red brick and genuine half-timber work with plaster are being used for the elevations, the roofs covered with red tiles, and the casements filled with leaded lights; the roof on the south front is covered with red tiles taken from an old building in the neighbourhood. The house is built angular in order to obtain a good view over a stretch of beautiful country. There is a wide corridor on the north front with the staircase opening out of it, and a large hall, oak-panelled and having an open timber roof, is provided. Facing this hall is an ornamental garden with hedges of yew and a sundial in the centre, the whole having an old-world aspect.

Stained Glass in New College, Oxford. A WORK of great interest, upon which Messrs. James Powell & Sons, of Whitefriars, have been engaged during several years for the society of New College, Oxford, has now been completed, in the cleaning and protection against future damage of the windows of the ante-chapel. It is not, in the usual sense of the word, a restoration, the beautiful fourteenth-century glass, which is beyond all reasonable doubt of English workmanship, having been replaced without addition or omission; but the result has been to restore nearly to its original brilliancy what had been obscured by dirt, and was in peril from its own frailty and the decay of the leadwork containing it. The ante-chapel, which is very spacious contains—besides the great west window, filled in 1784 with glass stained and afterwards painted (by Jervois) from designs prepared for the college by Sir Joshua Reynolds—seven windows, viz., two in the west wall (one on either side of the great window), two in the north wall, one in the south, and two in the east (one on either side of the choir). In the case of the two windows in the east wall, here, as was pointed out by Mr. Winston, in a paper read before the Archæological Institute at its meeting held in Oxford in 1852, the lights are narrower than those of the other windows in the ante-chapel or choir, and are six in number in each row instead of four. At some unknown date these lights had been re-arranged, and some, which had been mutilated, were filled in with glass of the same date and character taken from other windows, either those of the choir or (as seems to be indicated by signatures of the glaziers with dates 1775 and 1777, which Messrs. Powell discovered on fragments of the old glass) the great west window. Thus, in the northernmost of these two windows six apostles stood in the lower row, and in the southernmost one the order of the lights of the lower row had been confused. Messrs. Powell, following the general plan of re-arrangement proposed by Mr. Winston, have replaced the apostles in the upper tier of the more northerly window, but have somewhat varied his order below, restoring, however, the undoubtedly original arrangement of four Crucifixion groups. As, with the exception of some details in the tracery of the choir windows, no other specimen of the glass of William of Wykeham remains in either of his colleges, nor yet in Winchester Cathedral, the completion of this beautiful work is matter of great satisfaction. As the glass of the great west window was fast becoming fainter in colour, owing to chemical and mechanical waste, this relic of the eighteenth century taste has been framed between two layers of white glass, and will, it is hoped, be preserved for very many years.

The Pan-American Exposition. THE illustration on this page shows on the left the Machinery and Transportation building (Mr. Edward P. Green, architect), in the centre the Electric Tower (by Mr. John G. Howard, of New York), and on the right the Manufactures and Liberal Arts building (Mr. George F. Shepley, architect). An article on this exhibition was published in our issue for January 9th last.



GENERAL VIEW OF THE PAN-AMERICAN EXPOSITION AT BUFFALO, N.Y., FROM THE ESPLANADE.

Rag Fair. THE last remains of "Rag Fair" are situated in the thoroughfare known as Royal Mint Street. In the year 1756, or thereabouts, "Rag Fair" was in the zenith of its fame as a market for old and second-hand clothes, vieing in popularity with the later market of Petticoat Lane, and its western compeers in Holywell and Wych Streets Strand, W.C. They are now at last to come down, nearly all the property having been scheduled for the Tower Bridge improvement. The buildings in the street are ancient and date from the seventeenth century to about 100 years later. The interiors are exceedingly cramped. The rooms are reached by the narrowest of winding staircases, and their cubical dimensions would not receive the approval of present-day local authorities. When the Royal Mint was removed from the Tower early in the last century to the site immediately adjoining the back of these premises, a high brick wall was erected to separate them from the Mint grounds. There is evidence that a subterranean passage leading from these houses towards the river was at one time in existence. Royal Mint Street runs out of the Minories, a district which was at one time inhabited by gunsmiths and armourers. Like several other districts of the City, the Minories received its name from ecclesiastical associations. An abbey of nuns of the Order of St. Clare, called the Minories, was founded in 1293 by Edmond, Earl of Lancaster, Leicester, and Derby, a brother of Edward III. The abbey surrendered to Henry VIII. in 1539. The Minories was listed amongst the fashionable quarters of the City at one time, but not for long.

Portman Market. PORTMAN MARKET, which has been rebuilt upon the site of the old market in Church Street, Marylebone, is open for business purposes to-day. The market, which exists by virtue of two Acts of Parliament passed in 1830 and 1832, and is held by its present possessors under a lease from Lord Portman, stands in Church Street, Edgware Road, close to the goods depôt of the Great Central Railway, and the Great Western and other trunk lines. Those interested in the market point to the advantages of this situation for obtaining supplies of produce of all kinds, especially emphasising the facilities it affords for fish traffic from Great Grimsby and Hull by the Great Central line. It is claimed also that the market will be of great benefit to tradesmen in Paddington, Marylebone, Kilburn and other districts of north-west London, inasmuch as they will be saved the necessity of travelling four or five miles to the Borough markets. Billingsgate and Spitalfields, and three or four miles to Smithfield and Covent Garden, in order to purchase their supplies. The market, the site of which is rectangular in form, covers an area of 43,426 sq. ft., and new buildings of iron and steel have been erected at a cost of £40,000. These consist of eight avenues, radiating from a central point, where there is a lofty dome, together with a west, a north and an east avenue. The number of stalls is about 180, and in addition there are some shops on the street frontages. No tolls are to be levied on the goods that enter the market, the Portman Market Company relying for their profits on the rents paid by their tenants, who are supplied with electric light at the fixed charge of three-halfpence per lamp per day. Below the ground level of the market a large space has been excavated to provide cold storage for the convenience of those engaged in the frozen meat trade, which has developed enormously in London of recent years.

Excavations at Thermos, in the province of Ætolia, Greece, conducted by the Archæological Society under the direction of M. Sotirades, have resulted in the discovery of important inscriptions of the third century and portions of bronze statues. In the neighbouring valley some remarkable monuments have been disclosed, of solid construction and fine workmanship, together with a quantity of small figures in terra cotta, in a ditch which probably formed part of a temple. On the bank terra cotta inscriptions have been found in the characters used by the ancient Corinthians.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication

Work for Plasterers in Australia.

GREENOCK.—A. T. T. writes: "What city or town in Australia would be best for a plasterer to go to? What is its temperature? Kindly also give the name and address of the leading master-plasterer in the best district, the wages, what moderate living would cost, and any other advice."

Modesty does not characterise the above query. The best we can do is to refer "A. T. T." to the Emigrants' Information Office, Broadway, Westminster, S.W.

Builders' Book-keeping.

FROME.—H. C. writes: "There is, I believe, a book on book-keeping for builders, but I cannot ascertain the name of the publishers. Can you kindly supply the information?"

"Builders' Book-keeping: A Perfected System," by Mr. Sidney Saker, is published at 95–97, Finsbury Pavement, E.C. Its price is 3s.

"From Paddington to Penzance."

LONDON, N.—SHERBORNE writes: "Kindly give the title of Mr. C. G. Harper's book on places of interest in the West of England. I believe the journey was taken from London to Penzance, but I do not know the name of the publisher."

"From Paddington to Penzance," by Charles G. Harper, was published by Messrs. Chapman & Hall, Ltd.

Book on Incline Plane Machinery.

SPAIN.—G. A. B. writes: "Kindly mention the name and publisher of the latest treatise on the setting-out and construction of incline planes and incline plane machinery."

We have made enquiries, but cannot obtain particulars of any such work. Our contemporary "The Quarry" (49, Essex Street, Strand, W.C.) might be able to give some information on the subject.

Sketching at Wells, Somerset.

BIRMINGHAM.—SKETCH-BOOK writes: "I propose going for a fortnight's sketching and measuring tour to Wells, Somerset, and I should be glad if you could supply me with a few particulars of the district and special architectural places besides the Cathedral."

An illustration and some particulars of Wells Cathedral were published in our issue for August 23rd, 1899; but plenty of information about Wells will be found in the numerous architectural text-books. Besides the Cathedral, there is the Bishop's Palace, originally built in the form of a quadrangle by Bishop Joceline (1205–1244), and surrounded by a lofty circuit wall, and there are the cloisters. St. Cuthbert's Church is one of the finest of the many fine parochial churches in Somersetshire. Anyone visiting Wells would, of course, visit Glastonbury. In their "Cathedral Series" Messrs. George Bell & Sons, of York Street, Covent Garden, have published a book on Wells (price 1s. 6d.).

Slope of Roofs and Strength of Iron.

PENARTH.—H. writes: "Kindly answer the following questions, which were asked in the Intermediate R.I.B.A. examination: (1) The minimum slope for tiles and slates. (2) What is the difference in strength between wrought iron and cast iron? (3) Why are water pipes made stouter than waste pipes? (4) What is the proper slope for lead roofs?"

(1) Pan tiles are best laid to a slope of 24 deg.: plain tiles can be laid to any slope from 25 deg. to 60 deg. Slate roofs are often seen laid to a slope of 15 deg., but 30 deg. should be the least, and we would advise 45 deg. If the hips are to be mitred the angle should not be less than 45 deg., or very large slates must be used at the hip, and these look unsightly; on no account should small pieces be allowed. (2) The safe loads per sq. in. usually adopted are: for cast iron, tension $1\frac{1}{2}$ tons, compression 8 tons; for wrought iron, tension 5 tons, compression 4 tons; for steel, tension 6 tons to 8 tons, compression, 6 tons to 8 tons. (3) Because water pipes have to resist considerable pressure, due to head of water, whereas waste pipes have to resist practically none. (4) Gutters and flats should be laid to a fall of at least one inch in 10ft.

Standard Size for Eye-Bar.

CROYDON.—ROOFS writes: "Is there any *standard* table for the dimensions between arrows in the accompanying sketch of eye-bar heads. Carnegie gives a table of dimensions from 3in. diameter and upwards, but we require $\frac{1}{2}$in., $\frac{3}{4}$in., and so on up to 2in."

This question has been frequently discussed, and the standard shape varies according to the purpose for which it is required. For crane stays the rule is to make the eye round, the pin equal to the diameter of the rod, and the combined sectional area through the sides of the eye from $1\frac{1}{4}$ to $1\frac{1}{2}$ times the sectional area of rod, a stress of 3 tons per sq. in. under full load being allowed, giving the proportion shown in Fig. 1. When broad thin bars have to be connected by pins it is necessary to weld bosses on the sides, as in Fig. 2, in order to obtain sufficient bearing area on the pin and tensile strength in the sides of the eye. For the chains of suspension bridges, where the eye is formed by making a hole in a bar, the form shown in Fig. 3 is preferred, as it gives more resistance to bursting by the pin splitting through the grain of the material. For steel tie-bars in roofs, the Shaler-Smith type is considered best, as shown in Fig. 4. Figs. 2, 3 and 4 are for flat bars For round bars in roofs the proportions may be as in Fig. 5, the common octagonal portion being omitted as useless. HENRY ADAMS.

Books on Timber.

LITTLEHAMPTON.—RENUAD D'EST writes: "What books are there dealing with the formation and growth of all the different woods, their peculiarities when worked, their specific gravity and density, and the method of cutting out baulk timber to advantage, &c.? Please also name a good book on elementary building construction."

"Timber and Timber Trees: Native and Foreign," by Thomas Laslett (price 7s.), will furnish the desired information. "Tredgold's Carpentry," revised by Hurst (price 10s.), also deals considerably with timber. Rivington's "Notes on Building Construction" are the best books: Vols. I. and II. cost 16s.; Vol. III. 16s.; and Vol. IV. 11s. 6d. Cheaper, but useful, works are Mitchell's "Building Construction"—elementary stage, 2s. 6d.; advanced, 4s. 6d. They can all be obtained from Mr. B. T. Batsford, of 94, High Holborn. W. E. C.

Cost of Building.

LONDON, N.W.—QUESTION writes: "What would be the approximate price per ft. cube of a workman's cottage (detached) containing four rooms and a small scullery, of half-timber construction, the cells, posts and heads being of pitch-pine, left rough from the saw and oiled, built on a dwarf brick wall (1ft. 6in. showing above ground) and the roof tiled? It is genuine half-timber construction, not filled in with bricks. Also, the price per ft. cube of a stone clock tower, perfectly plain, on a small platform with a few steps up. Also the price of a clock for a tower, having three dials 6ft. in diameter, striking hours only."

The cost of such a workman's cottage would depend largely upon the cost of labour in the neighbourhood, and whether built under a competitive contract or simply to order. If all on one floor the roof will be costly in proportion to the cubic contents covered. Probably the cost would be about 8d. or 9d. per ft. cube, taking the greatest horizontal height multiplied by the height from top of footings to half-way up slope of roof. A plain clock tower as described might, perhaps, be put up for 5s. per ft. cube. A good 3ft. turret clock single face might be fixed for £25. A clock with three dials of 6ft. diameter, striking hours, would be about double the cost, or say £50. HENRY ADAMS.

Improving Damp Gardens.

NEWCASTLE-ON-TYNE.—B. P. writes: "Kindly recommend some treatment in cement, &c., for a small garden which is very damp and will not grow grass. Could Yorkshire stone slabs be used cheaply with success?"

First lay 2in. pipes not less than 15in. below the surface, about 20ft. apart, to an outfall,

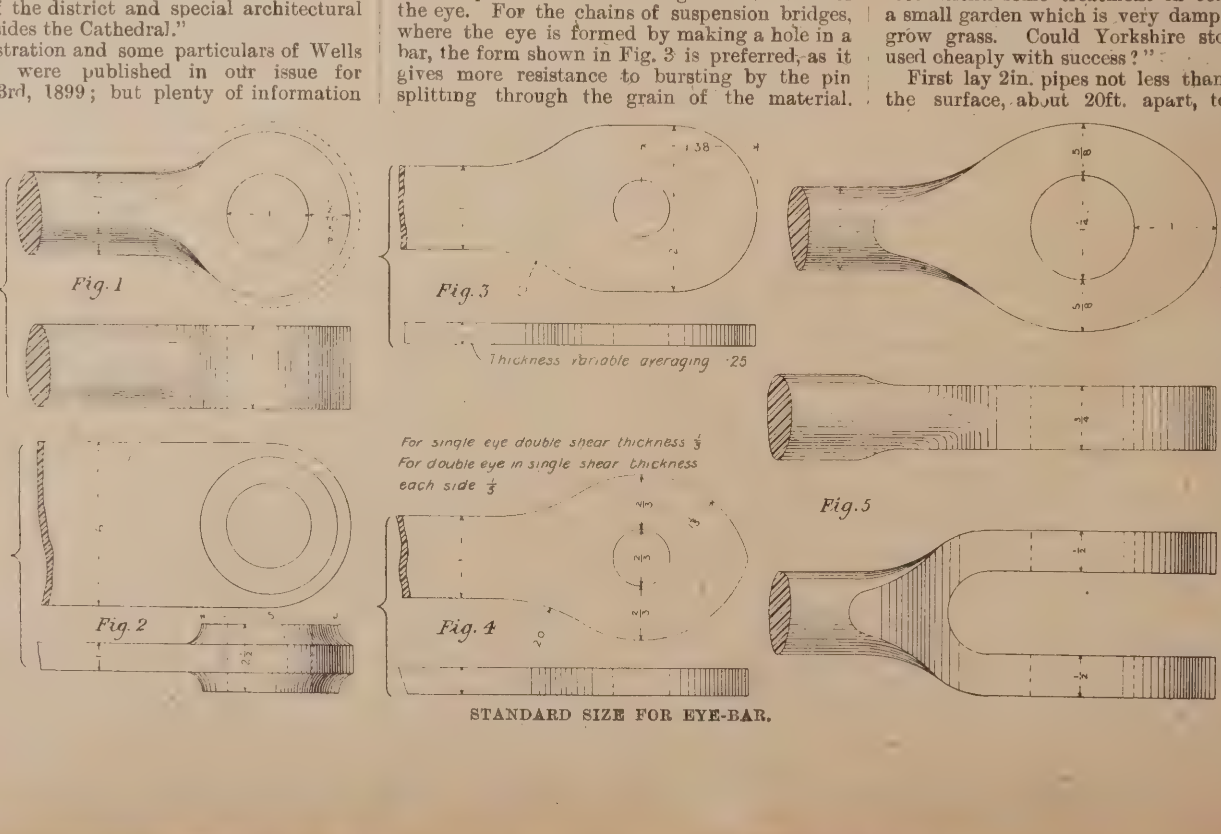


Fig. 1
Fig. 3
·138
Thickness variable averaging ·25
Fig. 2
For single eye double shear thickness ⅜
For double eye in single shear thickness each side ⅓
Fig. 4
Fig. 5

STANDARD SIZE FOR EYE-BAR.

Spread on these cinders or ballast. Lay a coating of cinders or burnt ballast 4½in. deep, and on this put either a layer of tar pavement (costing about 2s. 3d. per sq. yd.) or Yorkshire slabs or cement, each 2in. thick. If the site can be drained, a design for beds could be left in one or two places for plants. No size is given. A. E. M.

Charges in Respect of Deceased Architect's Practice.

YORK.—ANXIOUS writes: "Some time ago I succeeded to the practice of a deceased architect. Several works were uncompleted. I have an agreement with his executors by which they agree to pay me the usual professional charges for any work I may do for them. In one case the bills of quantities, specification, and other memoranda connected with a contract amounting to £4,000 had in ignorance been destroyed before I took over the practice. The deviation and alterations from the original intention were so great that I found it necessary to measure up the whole of the contract work as well as extra works amounting to nearly £2,000. The various accounts have been paid by the proprietors and everything settled up. What would be a fair charge for me to make on the executors for doing this work, which took nearly five months to complete?"

If, as querist states, "the work took nearly five months to complete," we are afraid there is no "usual professional charge" that would make the work remunerative. It is clear that "Anxious" is entitled to charge upon the basis of the charge for the original quantities, as he has done the work over again. A maximum charge in that case would be 2½ per cent., but should be subject to a deduction if less than this was agreed to be charged originally, *e.g.*, presuming the deceased partner charged 2 per cent., then 2 per cent. would be a proper charge for the re-measurement and adjustment of the final account. W. E. D.

Oak.

ST. PETER'S, THANET.—J. N. writes: "What is a good sort of oak to specify for joinery—doors, panelling, mantelpieces, &c.? What of Dantzig or Riga? Is there any difference between them in cost, appearance, &c.? Are they less expensive than 'wainscot'? Do they stand well? If one specifies 'wainscot,' should he get English oak or merely foreign oak selected for figure?"

Dantzig or Riga oaks are not good, nor are they suitable for joinery as compared with American wainscot or Austrian oak. They do not stand well. These woods are less expensive than "wainscot," which if so specified is usually considered to be American. English oak is not suitable for wainscot; although it is of excellent figure it is not kind to work, and not only does it invariably warp, but splits and cracks.

Elementary Questions in Building Construction.

HASLINGDEN.—BUILDER writes asking us to answer an elementary question set in the Advanced Building Examination of 1899.

These columns are not intended for answering such questions. If "Builder" will refer to "Rivington's Notes on Building Construction," or Mitchell's "Building Construction," he will find all the information he needs.

Copper Nails for Tiling.

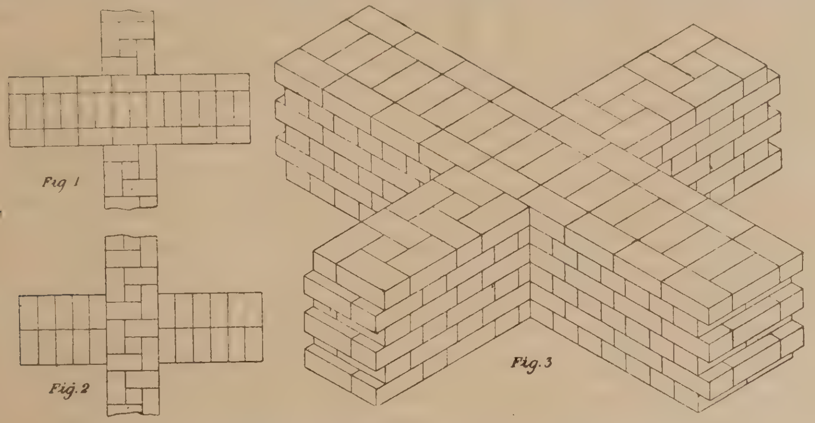
WOKINGHAM.—J. H. writes: "How many lbs. of 2in. copper nails are there to a square of tiling, laid to a 4in. gauge, and also to a 3in.? Do cast-iron pins rust and split the corners of the tiles?"

About 1¼lb. of copper nails are required for one square of ordinary tiling to a 4in. gauge, and about 1½lb. to a 3in. gauge; but, as the size so much affects the weight, we would advise "J. H." to count the number of nails in a square, and weigh an equal quantity himself; a square to a 4in. gauge generally requires 1½ hundred nails. Cast-iron pins rust, and are therefore not used; copper nails are expensive, and afford no advantage over composition, which we should advise to be used.

Bonding Junction of Cross Walls.

CLAPTON.—R. N. E. writes: "I should be glad if you would kindly answer this question: Based upon the accompanying plan draw to a scale of one-tenth full size an isometric projection, showing the plan of one course, elevations A B C D, and finished toothings at E and F."

Figs. 1 and 2 show small scale plans of the bonding in alternate courses, and Fig. 3 shows the isometric projection in the desired position.



BONDING JUNCTION OF CROSS WALLS.

It should be noted that since the advent of "polytechnics" and technical or trade classes the standard of accuracy has received a new interpretation in many subjects, and common angular projection such as this is known as isometric, while it is merely an imitation. It is a convenient substitute, and that is all. To use this method of projection, horizontal lines are measured along an angle of 30 degs. on either side, and vertical lines remain vertical, any scale being used as in an ordinary drawing. In true isometrical drawing the lines are foreshortened and reduced in the proportion of 1 to $\frac{2}{\sqrt{6}}$, or about 11 to 9. A cube would be so placed that the edges meeting at the nearest solid angle would be 120 degs. apart, something like a capital Y. HENRY ADAMS.

Openings for Architects in Egypt and the Colonies.

BRADFORD.—J. S. C. writes: "Is there any opening in the Government service for young architects and surveyors in Egypt or the Colonies? What are the qualifications necessary, terms of service, rates of pay, and status of such positions?"

Apply to the Agents-General for Canada, Victoria, New South Wales, Queensland, and Western Australia, all of whom have their offices in Victoria Street, Westminster, S.W., and to the Secretary of State for India, Whitehall, S.W., and the Secretary to Agent and Consul General for Egypt, Viscount Cromer, Cairo.

Formations inside Stones.

SHEFFIELD—J. J. writes: "A foreman of a stone-yard recently gave me a piece of stone (similar to sandstone and one of three) measuring 3in. by 2¾in., and almost spherical, which came out of a block of blue-stone. How did the stones get there?"

Our correspondent should have stated the kind of blue-stone. The spherical bodies referred to are generally deposited in the formation of a sedimentary rock, and assuming that the "blue-stone" referred to was of the usual kind the bodies were probably of concretionary formation. The concretionary structure is particularly observable in clays, limestones and ironstones. A concretion was formed by aggregating round some centre, such as a fragment of a plant or an animal. Clay-iron stone and impure limestone aggregated into spherical or elliptical forms (septaria) are of frequent occurrence in clay or shale. But many concretions may be found where no organic starting point can be detected, and are due to the irregular concreting of clay, sandstone, or limestone, owing to the spread of carbonate of lime through it, carried down by permeating water.

Books to Study for Civil Service Surveyorship.

FARNBOROUGH.—B. J. W. writes: "I have just entered a surveyor's office, and wish ultimately to enter the Civil Service as an assistant. What would be the best text-books to use for a course of reading in the following subjects: Drawing and theory of construction in architectural and engineering works, surveying, quantities, prices and estimates, use and properties of materials, plane trigonometry?"

E. W. Fritchley's "Art of Tracing" (published by the Education Society, Bombay); G. W. Tuxford Hallatt's "Hints on Architectural Draughtsmanship" (price 1s. 6d.); Rivington's "Notes on Building Construction" (Vols. I. and II., price 8s. each, Vol. III., 16s., and Vol. IV. 11s. 6d.); Mitchell's "Building Construction" (Elementary Stage, 2s. 6d., Advanced Stage, 4s. 6d.); Leaning's "Quantity Surveying" (price 12s.); Stephenson's "Estimating" (price 5s. 6d.); Snowball's "Plane and Spherical Trigonometry" (7s. 6d.); Angel's "Geometry" (Elementary, 1s. 6d., and Advanced, 8s.). These can be obtained from Mr. B. T. Batsford, of 94, High Holborn, W.C.

Drawing Perspective.

SOUTHPORT.—ACORN writes: "I wish to draw a perspective block of buildings on the enclosed plan (not reproduced). Where do the vanishing points come, and from where do I take my heights?"

Consult Mr. G. A. T. Middleton's book on "Linear Perspective" (price 1s.), published by Mr. B. T. Batsford, of 94, High Holborn, W.C.

Books on Granites.

LONDON, E.C.—W. J. T. writes: "What is the best and latest book dealing with granites."

We know of no book on granites alone, but you will probably find all you require in Geikie's "Text-book of Geology" (price 28s.), and Hull's "Treatise on Ornamental and Building Stones of Great Britain and Foreign Countries" (price 12s.). These books are published by Messrs. Macmillan & Co., Ltd.

Tests for Cement.

CROYDON.—R. E. L. writes: "Which of the following is correct: (1) 'Rivington's Notes on Building Construction,' Part iii., page 180 (3): 'A rough method of ascertaining whether the cement is cool enough for use, is by plunging the bare arm into the cement. If it feels hot the cement has not been sufficiently weathered, and requires further turning over.' (2) Mitchell's 'Building Construction,' advanced and honours courses, page 10, (f.) practical test: 'Bricklayers plunge their hands in the sacks of cement. If cold, it is dead and useless; if hot, it has not been sufficiently exposed to the air; if at blood heat, it is fit for use'."

Both paragraphs are correct as far as they go, but the test is a very rough one, as weather and the sensitiveness of the person will affect it, and again cements differ widely. The best rough test is to cast a small plate on a piece of glass and leave over night; if the cement is hot the surface will have cracked, and if perished will be very crumbly. As this test is easily made we see no advantage in the other, which is inconclusive.

SKETCH OF GABLE AT GHENT

BY E. STANLEY MITTOR.

TWO SKETCHES IN BELGIUM.

THE entrance to the Tribunal or Court of Justice at Malines, illustrated on the next page, is somewhat modern, being erected by Keldermans about 1617, along with the French artist Guyot de Beaugrant, and is the earliest example of the Renaissance in Belgium. The buildings have been skilfully restored by Blomme of Antwerp. The inside contains some fine chimney pieces and other interesting works of art. The old portions were erected by Rombaut Keldermans of Malines, in the late Gothic style; it consists of several picturesque buildings, enclosing several courts, and was formerly the palace of Margaret of Austria. The shop at Ghent or (Gand) illustrated on this page is a good example of the many fine buildings that Belgium can boast. It was erected in 1800. A special feature is the beautiful wrought-iron sign over the entrance, one of the best pieces of ironwork in Gand. The building is in stone, with iron casements and lead lights. The drawings are by Mr. E. Stanley Mitton.

Surveying and Sanitary Notes.

Portobello Promenade, Edinburgh, is to be extended westward at a probable cost of about £7,500.

A New Park at Ealing is to be opened to day. The Walpole Park, which is about 30 acres in extent, has been acquired by the Ealing District Council from Sir Spencer Walpole for the sum of £40,000. It was formerly for many years the residence of the late Right Hon. Sir S. H. Walpole, who died there in 1898. The park is well wooded, and it is intended as far as possible to retain it in its present form.

Masters and Men.

The Harrogate Plasterers, who went out on strike about a fortnight ago, have now resumed working on the masters' terms of $9\frac{1}{2}$d. an hour, and the arrangement will hold good for a couple of years. The men have also decided to work practically to the Leeds and Bradford rules.

Another Dispute at Leicester has occurred in the building trade; about sixty bricklayers and builders' labourers have ceased work at the new Wholesale Market in Halford Street, in consequence of a dispute as to the introduction of navvies to mix concrete. The builders' labourers, who receive $6\frac{1}{2}$d. per hour, claim that the work in question is work of a character which, under Sir William Markby's award, should be done by them and not by navvies, who are, it is alleged, paid at a less rate per hour. The Employers' Federation contend that things should be continued now as they were, pending arbitration, but the bricklayers' labourers demand that these navvies should be discharged before arbitration is entered upon.

The Amalgamated Society of Carpenters and Joiners, we learn from its forty-first annual report, has had an active year, and has expended in benefits to its members a larger sum than in previous years. The chief increase has been in dispute benefit, or, as such payments are termed, "trade privileges." Under this head the sum paid is £30,661, or £10,360 more than in any two previous years of the society's operations. This has been mainly caused by the prolonged strike on the part of the Belfast members for improved conditions. The matter seemed hopeless of settlement, as it had lasted nearly a year when it was recently referred to arbitration. Other considerable items of expenditure are unemployed benefit, £30,227; sick, £35,647; superannuation, £18,605. Despite this large expenditure the society has been able to pay its way without drawing upon its reserve fund of £204,089, and has, indeed, added to that fund a sum of £3,358. The total number of members at the close of the year was 65,012, an increase of 3,231 on the year. Of these 1,168 are in the United States.

The Chester Painters' Dispute.—At the end of last February some of the working painters of Chester came out on strike because their employers refused to sign a new code of rules. Fortunately both parties agreed to accept the friendly intervention of an arbitrator, the men returned to work immediately, and subsequently the mayor (Alderman H. T. Brown) at the request of both parties accepted the office of arbitrator. The points in dispute did not affect the rate of wages paid in the town, but chiefly the conditions of the men's employment in the country. Formerly the men were allowed 8d. a night lodging money up to four days, and the new rule they submitted asked for a shilling. On this point the arbitrator has given his decision in favour of the men, who will in future receive 1s. a night up to four nights. With regard to the distance which should entitle a man to return to town at the week end, the men's rule proposed that a workman employed on country jobs, over three miles and up to twenty miles, should be paid his third-class railway fare in and out every week, and over twenty miles up to thirty miles once a fortnight. In this instance the mayor made a slight alteration in the proposed rule bearing on the subject, its amended form being as follows: "Clause 2. All workmen employed on country jobs over three miles and up to fifteen miles to be paid third-class railway fare in and out every week; over fifteen miles and up to thirty miles distant, once a fortnight; over thirty miles and up to fifty miles, once a month; over fifty miles to remain on the job until completion."

New Wesleyan Church Buildings at Newland have been opened. These are to replace the old church at the end of Newland Avenue. The present buildings are only part of the whole scheme. The complete scheme provides for the erection of a new chapel, to be built on the site adjoining the present buildings, which are designed for Sunday-schools, with a large central hall. This large central hall provides accommodation for a congregation of 700, and the classrooms for 400 or 500 scholars. The total cost of the present buildings is about £7,000.

STANDARDIZATION OF BRICKS.

CONFERENCE AT THE ROYAL AGRICULTURAL HALL.

A conference between representatives of the Royal Institute of British Architects, the Institution of Civil Engineers, and brickmakers, was held at the Royal Agricultural Hall, Islington, on Friday afternoon last, to discuss the question of standardizing the size of bricks. Mr. Thomas Blashill (late superintending architect to the London County Council), who presided, remarked that a great difficulty arose by reason of the varying sizes of bricks needed to be used in the same wall, and it was very desirable that some standard should be determined.

Mr. Searles-Wood (the hon. secretary) read the resolutions drawn up by a joint committee of the two institutions named above. These were as follows:

The length of the brick to be double the width plus the thickness of one vertical joint.

Brickwork to measure four courses of bricks and four joints to a foot.

Joints to be $\frac{1}{4}$in. thick and an extra $\frac{1}{16}$in., making $\frac{5}{16}$in., for the bed joints, to cover irregularities in the bricks, thus giving a standard length of $9\frac{1}{4}$in. centre to centre of joints.

The bricks to be measured in the following manner:

Eight stretchers laid square end and splay end in contact in a straight line to measure 72in.

Eight headers laid side by side frog upwards in a straight line to measure 35in.

Eight bricks laid, the first brick frog downwards and then alternately frog to frog and back to back, to measure $21\frac{1}{2}$in.

The foregoing to apply to all classes of walling bricks, both machine and hand made, and facing bricks.

The Secretary then read three letters which had been received respecting the matter.

The first was from Messrs. Thomas Lawrence & Sons, of Bracknell, Berks, who wrote agreeing with the idea of standardizing bricks, but pointed out with regard to red bricks that there were bound to be some from the bottom part of the kiln which would be shorter than those from the upper part; in fact, to burn the darkest red colour it was necessary or usual to burn these bricks on end, with the result that the weight of the bricks above and the heat of the fire below often made them shrink nearly $\frac{1}{2}$in. in the length. As the dark red was the most difficult colour to obtain, Messrs. Lawrence saw very serious objection to it being specified in contracts that bricks should be of the standard size.

Mr. E. Holwill, of Temple Chambers, London, wrote saying that he considered the most simple rule to adopt would be that the size of bricks should be such that they should, in the work, run four to the yard and rise four to the foot (this enabling the quantity to be easily estimated at per ft. super. or per yd. super.). The foregoing included joints, and the width of a brick should be half the length less the thickness of the joint. The question then became one of thickness of joint; different classes of bricks necessarily requiring different thicknesses of joint. Glazed bricks and some kinds of facing bricks required $\frac{1}{8}$in. joint, and the sizes of these would then be $8\frac{7}{8}$in. by $4\frac{3}{8}$in. by $2\frac{7}{8}$in. For bricks requiring $\frac{1}{4}$in. joint the sizes would be less by $\frac{1}{8}$in., namely, $8\frac{3}{4}$in. by $4\frac{1}{4}$in. by $2\frac{3}{4}$in. Mr. Holwill said he had worked on the above rule and found it adjust itself to present requirements, giving less trouble than in cases where other sized bricks had been introduced. In his experience the question of the thickness of the joint had been the greater source of trouble.

Messrs. A. & C. Harston, architects, of Leadenhall Street, wrote expressing the opinion that, given true bricks and good mortar, with sharp and perfectly clean sand, a $\frac{5}{16}$in. joint for beds was an excellent thickness—better than $\frac{1}{4}$in., both in appearance and strength. The size of brick they endeavoured to promulgate was one $8\frac{7}{8}$in. long, $4\frac{1}{4}$in. wide, and $2\frac{5}{8}$in. thick. There was a difficulty in making London stocks and true-shaped facing bricks of exactly the same dimensions, and they thought there might be a rule that the latter should be thicker in each dimension by $\frac{1}{16}$in. or $\frac{1}{4}$in.

After these letters had been read the Chairman referred to the diversity of opinions expressed, and desired to know the views of the conference.

Mr. Joplin pointed out that the alteration of dies could be easily effected, but there was a great difficulty in the burning of the bricks, and he thought the variation arising from that cause would be in excess of what would be allowed from the standard. Another difficulty would be raised from the fact that some brickmakers would not care what the standard was so long as they could sell their bricks. As regards a standard brick, he considered one 8¾in. by 4¼in. to be satisfactory; the thickness was not so important as the width. He felt there should be a committee representing the brickmaking interests to decide what the standard should be. Then, if the specifying professions would observe that standard, the main difficulty would be over.

Asked by the Chairman what he thought was the variation in bricks required to be 9in. long, Mr. Joplin said that the minimum length might be as low as 8⅝in., but the maximum could be but little in excess of the 9in.

Mr. H. W. Richards (Northern Polytechnic) thought it mattered very little what the length was so long as there was a proper proportion between header and stretcher; and the great difficulty was in maintaining that proportion. He found that the bricks in the North of England were much thicker than those in the South. In his opinion it should be stipulated that bricks were not to be made of more than a certain thickness.

Mr. J. C. Hill, of Peterborough (chairman of the Clayworkers' Institute), said it was very difficult to determine what the shrinkage in a particular brick would be. There was also the difficulty arising from the wearing of boxes, the die becoming smaller and the boxes larger; and as repairs, say, to a row of machines could not be carried out all at one time there would be a slight variation in the size of the bricks produced. But still, this was very little as compared with wire-cut or slop-made bricks. They experienced continual difficulty in executing orders for bricks 3in. thick, as used in railway work. He thought it would be sufficient for the Committee to settle the standard and then leave the matter with the brickmakers, who, if they disregarded the standard, would soon suffer for their indifference, provided the architects and engineers thoroughly maintained their requirements.

Mr. George Wragge (chairman of the Kent and Essex Brickmakers' Association) said that as somewhat of a large stock-brick maker the term "slop-made" brick was painful to him. If they had not the advantages of Fletton they did endeavour to make and burn a brick which, he thought, was one of the best in this country, if not in the world. Brickmakers were quite capable of making any kind or size of brick required provided architects and engineers would pay the price; but these asked for the very best brick at the lowest price. The further South one went the smaller were the bricks. They were smallest in Italy, then in Holland they were 2in. thick, in London 2½in., while in Edinburgh the thickness increased to 3in. and 3½in. It would be an advantage if a standard size were determined. In 1898 his Association suggested that bricks 8⅞in. by $4\frac{3}{16}$in. by 2⅝in. would be the best so far as London was concerned. He referred to the case in which bricks of a "golden colour" were asked for, and wanted to know whether, with eight stretchers to measure 72in., this 72in. was to apply to such bricks *and* to best stocks.

Mr. Bernard Dicksee said the Committee, when considering this question, had to determine what size brick was most used in practice, and they selected as their standard one that was 9¼in. centre to centre of joints. He remarked with regard to stocks that many bricks were supplied as such which could not properly be so described.

Mr. S. E. Collier (Reading) thought a brick should be rather less in width than half the length. If it were possible to get the different brickmakers to agree to adopt a standard the object might be attained in course of time.

Mr. Goodenough (Sittingbourne) asked whether it was possible to stipulate that bricks from all parts of the country should be of a standard size. Till all earths and their manipulation were the same it was not possible. With clamp-burnt bricks the kind of earth used was specially important, for the shrinkage was determined by the proportion of water and whether the earth was "strong" or not. Then there was the drying and the variation of the heat during burning. The shrinkage between a well-burnt stock and a mild-burnt stock was not very great, but if a standard was to be determined it would be almost impossible for any maker to enter into a contract unless he had a price which would enable him to practically throw away all those bricks which did not exactly conform to requirements.

The Chairman suggested as a practical way of arriving at some decision that they might pass a resolution that it was desirable to get bricks as much alike as possible. This was seconded by Mr. Richards.

Mr. Bates (teacher of brickwork at the Northampton Institute and Chelsea Polytechnic) expressed the opinion that the great thing to have was proper proportion between length and breadth. Brickwork was executed cheaper in America, and he asked whether it was not a fact that bricks were smaller there. He strongly advised that, if the size were altered, bricks should not be made larger.

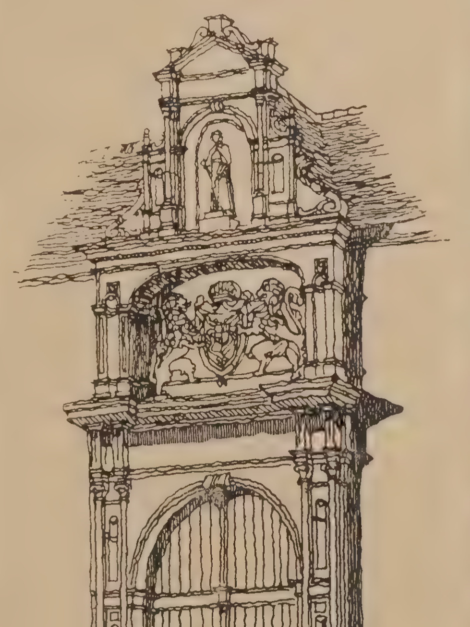
Mr. Hill thought some distinction should be made between a facing and an inside brick. There should be a standard size for facing bricks and one slightly smaller for inside bricks, as this best suited contractors' needs; they did not wish to "hammer down" the inside bricks.

Mr. A. Saxon Snell said what they wanted was a uniformity in the mortar joint; a thick joint meant settlement. Of course if cement were used it did not matter.

Mr. Radford remarked that not twenty-five per cent. of bricks were made to specifications. Builders bought just what they liked, and if architects specified a certain size those bricks which did not conform to it could easily be disposed of to the builders.

Mr. Blizard spoke, and Mr. Searles-Wood then put the following resolution to the meeting: "That it is desirable to form a committee to consider the propriety of standardizing the size of bricks." It was asked whether the North were to come down or the South to go up, but the resolution was carried. Steps will be taken to form as representative a committee as possible.

The R.I.B.A. June Examinations.—The June examinations of the Royal Institute will be held on the following dates: the Preliminary Examination on the 11th and 12th June, 1901. Applications must be sent in on or before the 4th May. The Intermediate Examination on the 11th, 12th, 13th, and 14th June, 1901. Applications must be sent in on or before the 4th May. The Final and Special Examinations from the 21st to the 28th June, 1901. Applications must be sent in on or before the 24th May, 1901. The testimonies of study, &c., with the necessary fees, must accompany the applications.



ENTRANCE TO THE TRIBUNAL, MALINES.
DRAWN BY E. STANLEY MITTON.

Law Cases.

Building without Depositing Plans: Another Case.—At Walsall recently Frank Pardoe, saddlery manufacturer, was summoned for erecting a building without the sanction of the Corporation, and without having deposited plans. The borough surveyor (Mr. R. H. Middleton) stated that the defendant had erected a workshop which was not in compliance with the Corporation by-laws, and which the Streets Committee would not allow to be occupied. There had been several similar prosecutions, but people continued to put up these buildings without depositing plans in the hope that they would not be found out. If undetected they escaped payment of rates. Defendant was fined 40s. and costs.

The Brompton Road Improvement.—The arbitration to assess the compensation to be paid to Messrs. Metcalf & Greig, architects and surveyors, for land in Brompton Road, between Brompton Square and Cheval Place, which has been acquired compulsorily by the Borough Council of Kensington for the purpose of widening the road, was concluded on April 20th at the Surveyors' Institution, Westminster. Mr. H. H. Collins put in the amended plans of the proposed block of residential flats. In these plans he had abandoned the seventh floor, which, according to the County Council regulations, could not be built without the provision of a fire escape, and has made the front of the building in Brompton Square. By this means he had been able to increase the size of the rooms. He estimated the rental of the eleven flats at £2,450 per annum, from which he deducted £800 for expenses, and £700 for ground-rent, leaving a nett profit of £950. He estimated the leasehold interest at sixteen and a half years' purchase, which, with the usual 10 per cent., amounted to £17,242. The ground-rent of £700 he estimated, at twenty-six years' purchase, at £20,000. From the total he deducted £8,000 for the cost of completing the building, which made his valuation £29,242. Mr. A. R. Stenning, surveyor, the first witness for the borough council, expressed the opinion that the claimants' original plans could not have been carried out, and that the amended plans of Mr. Collins were in many respects open to question. In his view the best plan for utilising the land would be to provide three shops in Brompton Road, with three floors of residential flats above. The ground-rent of £700 which had been created was an impossible rent, and could not be secured by any building which could be erected on the land. The umpire reserved his award.

Unfenced Planing Machines.—In the King's Bench Division of the High Court of Justice the case of *Cramp* v. *J. Garrett & Son* was recently heard. Plaintiff brought an action against the defendants (who are builders, of Balham Hill) for personal injuries alleged to have been sustained through a breach of the Factory Acts on the part of the defendants. Defendants denied liability. In the alternative they paid £150 into court as sufficient to satisfy the plaintiff's claim. In October last the plaintiff, who had been in the employ of the defendants for some time as a machinist, was working on an overhand planing machine when his foot slipped, and his left hand came into contact with the cutters, with the result that three fingers were cut off. The plaintiff alleged that his injuries were attributable to the neglect of the defendants in omitting to have the machine properly fenced or guarded in accordance with the Factory Acts. At the time of the accident plaintiff was in receipt of 32s. per week, and he now contended that he would not be able to follow his employment in the future. Defendants denied that they had been guilty of any negligence. They said that after the factory inspector had ordered a guard to be fitted to this particular machine they had one made, and instructed their foreman to put it on the machine. Unfortunately, the foreman did not put it on owing to the fact that the spring of the guard had been lost, and defendants said that if the plaintiff met his accident through negligence it was the negligence of their foreman in not carrying out their instructions. The jury found a verdict for the plaintiff, and assessed the damages at £300. Judgment accordingly with costs.

"Opalite": Infringement of Patent.—In the Chancery Division of the High Court of Justice last week Mr. Justice Cozens Hardy delivered judgment in the case of the *National Opalite Glazed Brick and Tile Syndicate* v. *The New Grand Hotel, Birmingham.* The action was one in which the plaintiffs, as assignees of Shelmerdine's patent of 1893 for affixing a glazed surface to walls, claimed relief in respect of an alleged infringement by the defendants.—His Lordship declared that the plaintiffs' patent was valid, that the defendants had infringed the patent, and he gave the plaintiffs the consequential relief. Defendants must pay the costs of the action. His Lordship also granted a certificate that the breaches had been proved, and awarded the plaintiffs damages, to be ascertained by enquiry.

The Employment of Girls in Brick Factories.—The case of *Squire* v. *Stanley Brothers, Ltd.*, was heard in the King's Bench Division of the High Court of Justice on Wednesday last. This was an appeal, by case stated, from the decision of justices of Warwickshire, sitting at Nuneaton, dismissing an information preferred by the appellant, an inspector of factories, against the respondents charging them with having unlawfully employed girls under sixteen years of age in their brick factory at Stockingford contrary to the Factory and Workshop Act, 1878. The schedule of this Act provides that "in a factory or workshop in which there is carried on (*a*) the making or finishing of bricks or tiles, not being ornamental tiles . . . a girl under the age of sixteen shall not be employed." Upon the hearing of the information the following facts were proved or admitted: The respondents made at the factory in question plain and glazed or enamelled bricks, both white and coloured, and also (*inter alia*) impressed glazed bricks. Two girls, Ellen Masser and Elizabeth Meacham, who were under the age of sixteen on July 16th, 1900, had for some time previous to that date been employed by the respondents in the factory. These girls were employed in carrying four or five (or a less number) of plain bricks from the dust kilns to the dipping sheds, where they were stacked and glazed by the dippers; also in carrying the bricks after they had been glazed from the dippers in the sheds to another place in the same sheds, where they were knifed or scraped; in carrying them from the sheds to the ovens, where the glazed bricks were baked and polished; and occasionally, but not often, in carrying the baked and polished bricks to the final stacking sheds. Eliza Meacham was, on the day in question and for a week at a time during the period of her employment, also employed in actually dipping the face of the bricks in the glaze. It was contended on behalf of the appellant that by the combined effect of section 38 of the Factory and Workshop Act, 1878, and the first schedule of it, there was an absolute prohibition against the employment, in any place within the close or curtilage of a factory where bricks were made or finished, of girls under the age of sixteen years, and further that the processes performed upon the rough bricks constituted a finishing of bricks within the meaning of the first schedule of the Act. On the part of the respondents it was contended that there was no absolute prohibition as alleged, but only a prohibition to employ girls under sixteen in the processes of making and finishing bricks and that the above processes did not constitute a finishing of bricks. The justices were of opinion that the contention of the respondents was correct. The Court allowed the appeal. The Lord Chief Justice said that he did not wish to express any opinion as to whether there was an absolute prohibition against employing girls under sixteen in factories for making bricks. He was clearly of opinion that what was done in the part of the factory where the girls were employed was finishing of bricks, within the meaning of the first schedule to the Act. The case must go back to the justices. Mr. Justice Lawrance concurred.

Fire-resisting Construction between Trade and Private Premises.—The case of *Dicksee* v. *Hoskins* was heard last week in the King's Bench Division of the High Court of Justice. This was an appeal from the decision of a metropolitan police magistrate allowing an appeal under the London Building Act, 1894, from a notice of objection to a proposed building served by the appellant, who is a district surveyor under the Act, upon the respondent, a builder. The proposed building was situated at No. 87, Old Kent Road, and was the re-erection of a licensed beerhouse on the site of an old beerhouse called the "Horse Shoe." The trade of the beerhouse was to be carried on in the basement and on the ground floor, and the licensee and his family were to reside in the upper floors of the building. The whole of the building was to be covered by the justices' certificate and Excise licence. The floors separating the ground floor from the first floor and the staircase leading to the first floor were not intended to be constructed of fire-resisting materials, and the learned magistrate found that, if sub-section 2 of section 74 of the London Building Act, 1894, applied to the building, the provisions of that section would be contravened. (Reports of the case when heard in the Southwark Police Court, were published in our issues for October 24th and 31st last). The learned magistrate also found as a fact that the basement and ground floor of the building were intended to be used for the purposes of the trade of a beerhouse, and that the part above the ground floor was intended to be used as a dwelling-house for the licensed occupier, but held that the case was governed by the decision in *Carritt* v. *Godson* (1899, 2 Q.B., 193), and allowed the appeal and overruled the objection of the district surveyor. The district surveyor appealed. The Court dismissed the appeal. The Lord Chief Justice said that he did not base his decision entirely on *Carritt* v. *Godson*, because in that case there was an additional ground for deciding that the house there in question was not within the London Building Act, 1894, section 74 (2)—namely, that the lobby which gave access to the staircase of the house opened into a back yard. In his opinion, the section was intended to apply to buildings part of which were used for trade and manufacture and the other part as a dwelling, and it was not intended to apply to a building certain rooms of which were used as a dwelling. The appeal would, therefore, be dismissed. Mr. Justice Lawrance concurred. He said that he agreed to the extension of the principle in *Carritt* v. *Godson* laid down by the Lord Chief Justice.

Builders' Notes.

In the Isle of Thanet Hospital the whole of the wood block floors are to be laid on the "Fawcett" system of Messrs. Mark, Fawcett & Co., of 50, Queen Anne's Gate, Westminster. There are about 2,500yd. Messrs. Langham & Osborne, of Ramsgate, are the architects.

Stephen Dustow, of Chobham Road, Stratford, died recently. In partnership with Mr. Thomas Knight—who survives him, at the great age of eighty-eight—he carried on active building operations for many years. It was in 1853 that the firm commenced this work.

An Exhibition of Carpentry and Joinery will be held in connection with the Carpenters and Joiners' Companies at Carpenters' Hall, London Wall, from Wednesday, June 5th, until Tuesday, June 18th. Exhibits of works in wood and wood carving must be delivered before Saturday, 11th inst.

An Exhibition of Inventions.—An addition of considerable technical and popular interest will be made to the many attractions announced for this month in connection with the Naval and Military Exhibition at the Crystal Palace. A section will be devoted to Inventions, Patents, and Designs connected more or less with naval and military matters, which will show the progress we have made since the days of the 1851 Exhibition. Inventors who wish to exhibit can get particulars of free spaces from the technical adviser and manager, Mr. Henry C. Braun, C.E., Inventors' Engineer and Specialist, 236 to 238, Pentonville Road, King's Cross, London.

Payment for Hoardings.—Recently Mr. Robert Allan, of Rankine Street, Dundee, wrote to the Works Committee of the Dundee Town Council drawing attention to the charge which is now being made by the Commissioners for portions of streets enclosed by hoardings during building operations. He agreed with the desire of the Commissioners that these hoardings should only be allowed to remain up during the minimum time required for the public safety and the due execution of the work to be done, but thought that the charges now being made were too heavy. These charges are 1s. 8d., and 4d. per sq. yd. per month, or equal to a rate of £18 3s., £12 2s., and £6 1s. per pole per annum. Dealing with this as it affected himself, it appears he was charged for ground enclosed by hoarding in one street, £12 2s. per pole; he was paying at the rate of 5s. per pole for this ground, so that the Commissioners were charging an extra rate for the temporary use of this ground nearly fifty times the amount of the feu. He suggested as a more effective way of securing the end in view that no charge—or only a small charge—should be made for the portion of street enclosed during a limited time fixed by the Commissioners or their engineer; and if the contractors exceeded this limited period, then the 1s. 8d. or 4d. rate should be put on for the remaining period. The burgh engineer has been asked to consider the matter.

A Fire Test with Two Iron Doors.—We have received No. 60 of the British Fire Prevention Committee's publications. It deals with a test made with an iron framed door with stiles and rails on both sides, and a similar door with stiles and rails on one side only, as frequently described in "Building Act" and "Insurance" specifications respectively. The object was to record the effect of a fierce fire lasting one hour, the temperature being gradually increased to 2,000 degs. Fahr., followed by the sudden application of water for five minutes. The door openings were 3ft. 3in. by 6ft. 9in. The fire was applied from one side, and the doors opened inwards on that side. The following is a summary of the effect: In five minutes the door with stiles and rails on one side only bulged inwards ¾in.; in eight minutes the other door bulged inwards ⅜in. above and below the centre fastenings; in eleven minutes the bulge on the door with stiles and rails on one side only increased to 2in., and in eighteen minutes to 2½in.; in fifty-nine minutes this door was red-hot almost all over, and one of the top corners was bent inwards ¾in., the bolt having dropped; in fifty-nine minutes also the other door was red-hot, and the bulging had increased to almost 1in.; but it will be seen that this door withstood the test much better than the door with stiles and rails on one side only. The panels in both doors were of ¼in. steel.

The Boom in the Building Trade of Inverurie consequent upon the decision of the Great North of Scotland Railway Company to remove their works from Aberdeen to that place still continues. The huge workshops are approaching completion. The main part of the new station has been almost finished, and operations have been commenced on the up platform and siding for the Oldmeldrum trains. The provision made by the railway company for the housing of their workmen is on an extensive scale, comprising, as it does, the erection of seven large blocks of buildings, providing accommodation for 112 families. Two of these blocks, containing sixteen four-roomed tenements each, face Harlaw Place, and the remaining five, so designed as to provide three rooms for each family living in them, form new streets, to be called King Street, Queen Street, and Princes Street. All the houses closely resemble each other in outward appearance, and they have been so arranged that only four tenants will use each of the entrance doors. Ample accommodation has been provided to the rear of the buildings, and no less than twenty-eight wash-houses have been erected. The sewerage system of the town is being extended along Harlaw Place so as to connect with the drains of the buildings. The contractors for the dwelling-houses are—Messrs. Ogg & Sons, Woodside, and Mr. John Smith, Kintore, masons; Mr. Hendry, Keith, carpenter; Messrs. James Laing & Son, plumbers; Messrs. J. & R. Seivwright, and Mr. R. Moir, Inverurie, plasterers; Mr. S. Christie, sen., Dyce, slater; and Mr. Wm. Duncan, Inverurie, contractor for the roads. Buildings other than those erected by the railway company have been rapidly springing up. In North Street the foundation of two new shops and a dwelling-house have been laid, and a commencement has been made with a new bakeshop at the end of Falconer Place—itself an entirely new street. Off Blackhall Road Messrs. Byre & Park, builders, Aberdeen, are erecting a large tenement house.

Keystones.

The New Public Baths and Wash-houses at Battersea, which have been erected by the Battersea Borough Council in the Nine Elms district at a cost of about £40,000, have been opened.

The Parish Church of Macclesfield, Cheshire, was opened last week after its restoration at a cost of £21,000. The original parish church of Macclesfield was founded by Queen Eleanor, wife of Edward I.

Skibo Castle has been undergoing considerable alterations for Mr. Andrew Carnegie. About £40,000 has been spent. The public apartments are all new, and special attention has been paid to the providing of a spacious library. Mr. Carnegie's favourite residence is five miles from Dornoch, Sutherlandshire, which is five miles from a railway station.

Profitable Artisans' Dwellings.—At last week's meeting of the Hornsey District Council, the Artisans' Dwellings Committee presented a report showing that the council's 108 dwellings at Hornsey had produced £1,073 during the last six months, and after paying off the half-yearly amount of principal and interest on £31,000 there remained a balance in hand of £483. The rents are 6s. 6d. and 9s. 6d. a week for a separate house and garden.

St. Ambrose School, Sandycroft, has been enlarged by the addition of a new building, which has been erected at the sole expense of the Sandycroft Foundry Company at a cost of £700. It has been designed by Mr. H. Swetenham, and is of red brick. Apportioned into two lofty rooms, which are wainscotted to harmonise with the old building and separated from the old room by means of a glass and wooden partition, it exactly doubles the accommodation of the school, bringing it to the number of 210. The dimensions of one room are 18ft. sq., and the other 32ft. by 18ft.

The Old Saxon Church at Overton, which is said to be the oldest ecclesiastical building in Lancashire, is unhappily proposed to be restored. It existed prior to the Norman conquest, and was restored about the twelfth century. The interior furnishings are of the quaintest description, and include an old three-decker pulpit with desks for preacher, reader and clerk, one of the very few yet existing in the country. The proposal is looked upon in antiquarian circles as little short of vandalism, and the resolution to apply for a faculty submitted to a meeting of parishioners was only carried by twenty four votes to twenty.

The New Rates Office at Bristol, in Broad Street, has been completed. The building is in continuation of the line of the Council House. A large public hall gives ample provision for the public on the outer side of a long counter, behind which full provision is made for the large staff of clerks. Behind this and underneath the new council room is a large apartment to be used by the collectors. Also on the ground floor is the office of the assistant overseer. On the first floor there are the offices of the city valuer and his staff, in the front portion of the building, while behind is a large room for the assistant overseer's staff. On the top floor is the room of the city valuer's draughtsmen, and behind this is the new office for the inspector under the Food and Drugs Act and the Shop Hours Act.

A New Wesleyan Church at Platt Bridge, Wigan, is being erected. The church is to be in the Gothic style, and will consist of a nave 68ft. long by 39ft. wide and transepts 48ft. 6in. wide inside measurements. There is an end gallery, and accommodation will be provided for a mixed congregation of 650 persons. The church is to have an octagonal apse for chancel and organ chamber alongside it. At the rear there will be two vestries, one for the choir, and one for the minister, each supplied with lavatory, &c. There is also a church parlour, each capable of seating 100 people. At the front end there are to be two cloak-rooms, to be used by the congregation. The walls are built of best pressed brick, with stone dressings, and the seats, pulpits, and other joinery of pitch-pine. The cost will be about £4,000. The architect is Mr. John Wills, F.S.Sc., of Derby and London, and the contractor is Mr. David A. Ablett, of Wigan.

A Lych Gate has been erected at the northern entrance of All Saints' Church, Hollingbourne, as a memorial of the late Mr. R. G. de V. Thomas. It was carried out by Messrs. Harry Hems & Sons, of Exeter, and is of English oak, in the Early English style.

New Public Swimming Baths at Beckenham have been erected by the District Council on the land on which the old Clock House stood. A technical institute is also being erected in connection with the baths. They have been designed by Mr. Angell, the Council's surveyor, and the total cost is estimated at about £26,000.

The New Church of St. Martin, Upper Knowle, has just been consecrated. The building is designed to eventually accommodate 700 persons; but the work completed is limited to the chancel, vestries, &c., and two bays of the nave. The style of architecture is Early English, and the building is of pennant stone with Bath stone dressings. The portion completed will cost about £3,000. Mr. W. V. Gough is the architect, and Mr. Maton Durnford the contractor.

Queen Street, Glasgow.—The National Bank buildings are about to give place to a large warehouse which is being erected for Messrs. Hunter, Burr & Co. warehousemen, of Jamaica Street. The style is Renaissance, and the architects are Messrs. H. & D. Barclay, Glasgow. It will consist of seven storeys, and the ground floor will be reserved for shops. A main doorway in the centre of the building will give access to the upper flats, which are to be occupied by the firm themselves.

What Bristol is Doing to House its Working Classes.—For years it has been the subject of complaint on the part of some of those specially interested in questions affecting the welfare of the working classes that the Bristol Corporation, while by street improvements destroying many of the old rookeries in which scores of familes lived, had done absolutely nothing to put in force the constructive provisions of Acts of Parliament passed with a view to facilitating the provision of dwellings for the labouring classes. The Corporation now has twenty new houses ready for occupation; sixteen dwellings upon which the contractors have almost but not quite finished their work; twenty-four in less advanced stages; and ten more, the erection of which has been sanctioned by the council, but which as yet exist only on the plans in the drawing office of the city engineer.

The New Union Church at Lynn has been opened in Wisbech Road. It is a cruciform building, with nave, aisles, transepts and square apse used for the organ and choir gallery. The general design is a modified form of the Early English style, with light arches and pillars dividing the aisles from the nave, double lancet windows in the aisles and quatrefoiled circular windows in the clearstory glazed with coloured glass. The rear wall is lighted with a group of five lancets, the transepts by three each; while over the organ is a circular window with two small lancets on either side. The roof is of open beam work in light, varnished wood. The organ, rostrum and general seating have been removed from the old church. The new church is 60ft. by 40ft., with seating for 320 persons, and has been built by Mr. W. F. Smith from designs by Mr. J. L. Carnell, Tuesday Market Place, Lynn.

Housing at Birmingham.—The Housing Committee of the City Council are considering certain schemes for the erection of an experimental block of tenements on the flat system in Potter Street. The plans of four schemes had been prepared, and these provide for the erection of four-storey blocks, each containing from sixty to seventy tenements, with frontages in Potter Street and Staniforth Street. The committee recently had an interview with Messrs. Newton, Crouch, McEwan, and Buckland, who attended as a deputation from the Birmingham Architectural Association for the purpose of asking that the plans for the erection of dwellings should be thrown open to competition. It was pointed out, however, that the plans for the proposed buildings in Potter Street and at Bordesley Green were too far advanced for the committee to comply with the request of the architects, but a hint was given them that in any future scheme their views will be favourably considered.

A Cottage Hospital at Sleaford is to be erected as a memorial to Queen Victoria.

New Board Schools at Cleethorpes are to be erected in Bursar Street, at a cost of £13,530, including £1,452 the price of the site. Accommodation will be provided for 360 boys, 360 girls, and 230 infants.

Mount Tabor Chapel, Stockport, has been reopened, after improvements in the interior at the total cost of £400. The electric light has been introduced, the place has been re-decorated and the ventilation improved.

Boothroyd Church is proposed to be renovated, and a faculty is to be applied for. The things to be taken in hand are the thorough overhauling of the organ, the cleaning of the walls, roof and general repairs, the extension of the chancel and the heating apparatus. The estimated cost is £2,500.

The Restorations in the Castle of St. Angelo, Rome, which are now being carried out, have resulted in the discovery of some curious frescoes of the fifteenth century. It is even hoped that possibly thick coatings of whitewash still cover the frescoes by Pinturrichio representing the whole of the Borgia family. It is known that such frescoes existed in the time of Julius II.

The Tom Hughes Memorial.—£6,000 has been subscribed towards the scheme for the erection of additional buildings at the Working Men's College in Great Ormond Street as a memorial of the late Tom Hughes, a former principal of the institution. In all a sum of not less than £15,000 will be required for the erection of lecture rooms, a laboratory, and for other purposes, but as soon as £8,000 has been subscribed it is proposed to begin building operations.

A Discovery has been made in the course of the excavations now in progress just outside St. Bride's Churchyard, Fleet Street, of a cast either of a sculptured bust or of a human face. Probability points to the former, as the features are of the purest Hellenic type, and one of the British Museum authorities is of opinion that it represents the head of Pallas Athenæ. The cast, which was discovered at a stratum in the foundations known to be 200 years old, reposes temporarily in the parish church of St. Bride.

"The New Century Hotel" is the name of a building situated in Holm Street, Glasgow, which is unique of its kind. It is a poor man's house, and is a kind of half-way house between the lodging-houses and the palatial West End palaces. Mr. Thomas Paxton, who has in the past achieved successes in the model lodging-houses under Glasgow Corporation, and more recently on his own behalf, is responsible for the inception and carrying out of the scheme. The hotel has seven flats and 400 single cubicle bedrooms. Messrs. Frank Burnett & Boston were the architects.

The New Swiss House of Assembly is expected to be opened at Berne this year or early next. The chief building is already nearly completed. The buildings are situated in Berne Place, and will be the future place of assembly of both Houses of the Swiss Parliament, the Council of State, and the Conseil Nationale, the representatives of the cantons and the representatives elected on the basis of one representative to each 20,000 of the population. The building faces north. Behind it are the Alps and the Bernese Oberland, and the buildings in front of it are to be cleared to make a great square. To east and west in the Berne Place are other Government buildings—the War Office, Home Office, and Treasury.

The Demolition of Seven Historic Houses at Windsor, which were good examples of the architecture of the reign of Charles I., has been begun by the Corporation. The houses adjoin the present vicarage of Windsor, which formerly was a residence attached to Windsor Castle. They also adjoin a large piece of waste Crown land which was offered to the Corporation some time ago. Upon this and the site rendered vacant by the demolition of the houses, it was proposed to erect a Volunteer drill hall, as a memorial to the late Prince Christian Victor, but the project fell through owing to lack of support. The Corporation have condemned the houses—their own property—as unfit for human habitation, and their destruction will remove one of the most interesting landmarks in Windsor.

Mr. W. J. Hale, of St. James Row, Sheffield, has been made a fellow of the Royal Institute of British Architects in accordance with the unanimous recommendation of the Council of the Sheffield Society of Architects.

Messrs. F. McNeill & Co.: a Correction.—We regret that in our notice of the exhibit of Messrs. F. McNeill & Co. at the Building Trades' Exhibition (see page i of the supplement to our last issue) the price of their fibrous asphalt was given as 7s. 6d. per yard super. instead of 1s. 6d.

A Wigan Competition.—Mr. John B. Thornley, architect, of Darwen and Blackpool, has been successful in a competition for a large block of buildings in Wigan, including arcade, shops, suites of offices and assembly-halls. The premises are estimated to cost about £35,000.

Engineering Notes.

Institution of Civil Engineers.—At the ordinary meeting on April 23rd, Mr. James Mansergh (president) in the chair, it was announced that three associate members had been transferred to the class of members: Messrs. R. A. Carr, G. W. Partridge and H. P. B. Rigby. The last ballot of the session resulted in the election of one honorary member, Mr. James Dewar, M.A., LL.D., F.R.S.; six members, Messrs. A. M. J. Alby (Paris), W. F. Brown (Cardiff), W. R. Herring (Edinburgh), M. R. Mellor (Coatzacoalcos, Mexico), F. Mills (Ebbw Vale, Mon.) and P. Watts (Newcastle-upon-Tyne); and fifteen associate members, Messrs. W. C. Carter (London), H. M. Clarke (Perth, West Australia), R. S. Cole, M.A. (Cantab.) (Edinburgh), A. M. Downie, B.Sc. (Glasgow), Stud. Inst. C.E. (Glasgow), F. A. Hurley, F.C.H. (Egypt), A. J. Irwin, B.A.I. (Dublin) (Bangkok, Siam), A. C. Kelley, Stud. Inst. C.E. (London), J. Kirkland, B.Sc. (Victoria) (London), J. Lord (Halifax). J. C. O'Connell, B.E. (Royal) (Athlone), G. H. Pearson, Stud. Inst. C.E. (New Swindon), D. W. Ross (London), W. H. B. Savile, Stud. Inst. C.E. (Hull), S. A. Smith (Manchester) and R. E. Wright (Cape Town).

Yarmouth Harbour is being considerably improved, and the first section has just been completed. This is the construction of a new quay heading upon the South Quay, and the provision of deep water berths that will enable the largest steamers using the port to come to this quay. The scheme provides for repiling the whole length of the South Quay from the Bridge to Friar's Lane. The portion now completed is from the Bridge almost to the crane, roughly, perhaps one-half of the total of the quayage to be reconstructed, which will cover a distance of 2,200ft. The expenditure involved will be not less than £20,000. The work is being done by the Port and Haven Commissioners' own staff, under the superintendence of their engineer, Mr. J. Green. Huge wooden piles, ranging up to 40ft. in length, iron shod, and 12in. square, of memel fir or pitch pine, creosoted at the Commissioners' works at Gorleston, have been driven in front of the old quay heading by a steam pile. At intervals all the main piles are secured to dwarf piles, driven below the surface of the roadway, by steel tie rods, some 20ft. in length. At the exposed ends of the pile a massive timber capping has been bolted to the logs. The raising of the quay left the quay tramway at too low a level, while earth filling at the back was also required. The metals have therefore been placed on a higher level, and the "four foot" paved with granite setts. The cost is estimated at £8 12s. per foot run.

The New Pavilions at the Fever Hospital, Blackburn, are being warmed and ventilated by means of Shorland's double-fronted patent Manchester stoves, with ornamental tiled sides and with descending smoke flues, supplied by Messrs. E. H. Shorland & Brother, of Manchester.

The First Metal Railway Bridge ever erected has just been removed from the position it has occupied for nearly eighty years, being erected in the year 1823 across the River Gauntless, at the western extremity of the original railway line at St. Helens. The framework was entirely composed of cast iron, resting upon ordinary stone foundations in the river. In consequence of the developments in the coal trade in the vicinity, the old bridge has been replaced by a more massive structure, to carry the heavy mineral engines and loads now in vogue upon the North Eastern Railway. Doubt exists as to the identity of the engineer of the old bridge. It is claimed that the plans and specifications were those of George Stephenson and John Dixon, while others suggest that a Mr. Storey—probably Mr. T. Storey, at one time engineer of the old Stockton and Darlington Railway—superintended its erection. At that period civil engineering was scarcely recognised as a distinct profession; the bridges erected previously to the year 1825 were constructed by either architects or millwrights. Bonomi, of Durham, was the architect employed to build the first bridge on the Stockton and Darlington Railway at Darlington. The first iron road bridge built in England is that at Ironbridge, Shropshire, which was erected in 1779.

Trade and Craft.

The following are some supplementary notices of the Building Trades' Exhibition:—

BRITISH LUXFER PRISM SYNDICATE.

The British Luxfer Prism Syndicate, Ltd., of 16, Hill Street, Finsbury, E.C., have executed a very effective piece of basement lighting in Old Jewry Chambers. The width of the roadway is 25ft., the height of the buildings on each side 60ft., and the aperture for light, so far as windows are concerned, only 10in.; but, despite these unfavourable circumstances, Luxfer prisms in combination with vertical prism plates (called "Lucidux frames") were put in with such success that the dark passages have been made bright, and dingy lumber rooms turned into well-lighted offices commanding a high rent. The multi-prism pavement lights are made of the best clear crystal glass, and the vertical prism plates are made with prisms at a variety of angles to suit different requirements; for by their use the light, instead of being thrown to the floor and there lost, is projected at a higher level, thus making the lighting very much more effective. Luxfer prisms have been tested by the British Fire Prevention Committee with marked success. Another speciality of the firm is the electro-copper glazing. Strips of copper are placed between the panes in "leaded-lights," and copper is deposited on them till the whole is firmly held—in fact, so firmly that no supporting bars are required.

THE AEROGRAPH CO., LTD.

Colours can be applied by the "Aerograph" very rapidly. The handpiece is like a stout pencil, and is used with the greatest freedom, while the range of work varies from a fine line to a solid band of colour almost an inch wide. The handpiece is connected to the air-pump by a length of rubber tubing. Besides this instrument, which is intended for artistic purposes, the firm also make the "Aerograph Spray-Painter." This is specially designed for decorators and painters, and the manner in which colours can be blended by its use needs to be seen to be fully appreciated. The sprayer is applicable to both oil and distemper colours, and it is possible to lay one tint over another without waiting for the first to thoroughly dry. The address of the firm is 30, Memorial Hall Buildings, Farringdon Street, E.C.

THE ARTISTIC TILE CO.

The Artistic Tile Co., of 35, Berners Street, W., make the Cloisonné hand-glazed tiles used largely for wall decoration, instead of the ordinary embossed tiles. This decorative tile is, however, sold at a price which is but slightly more than that of the ordinary tile, with which it is in fact being used to form many beautiful designs. Another speciality of this firm is white terra-cotta, and judging from the price of 15s. per foot. run quoted for 2ft. 6in. balustrade, including cap and base shown at the stand at the Exhibition, this material should prove most useful as a substitute for stone. At the same stand the Architectural Fitments Co. also showed a fine mantelpiece and a chimney-piece in carved walnut of Renaissance design, and some good examples in wrought-iron and wood as applied to door-furniture, balustrades, bridges, grates and fencing.

OATES & GREEN, LTD.

This firm, whose address is at Halifax, have just opened a London office and showrooms, at 27, Chancery Lane, W.C. Messrs. Oates & Green make excellent quality glazed bricks of all kinds. Their heavy fireclay lavatory basins with self-contained overflow are made, either on pedestals, with lugs to build into wall, in ranges or triangular for corners. These are largely used in schools, and admirably resist rough usage. The firm also supply the lavatory taps and waste plugs, and their automatic flushing tanks, trough closets and latrines are most useful. A large number of patterns of polished hard wood closet seats are made. The circular and patent taper urinals in glazed ware are now well known. Their new "Beresford Fire" is built of glazed firebricks, the back of the fire being so formed as to give one and three-quarter times the area of radiating surface; these fires burn soft coal, coke and anthracite. The thorough combustion of every kind of fuel occurs, only a small quantity of fine ash being left. A rub with a dry cloth is all that is necessary to clean them, and the ash can be readily removed, whether the fire is burning or not. These fires were "Highly Commended" by the Smoke Abatement Committee. Other specialities are heavy fireclay sinks and wash-tubs, gulleys, access pipes, interceptors, and channel siphons and bends and sanitary tubes with diameters from 18in. to 42in. in 3ft. and 3ft. 6in. in lengths.

YORKSHIRE PATENT GLAZING CO.

The chief features of the "Premier" system of glazing (the patent of the Yorkshire Patent Glazing Co., of Liversedge) are that it is perfectly dust-proof and water tight, does not need putty, allows for the full expansion and contraction of the glass, has no drip whatever from condensation, and absorbs any vibration from machinery and other causes. The glass is held tightly between asbestos cords, fitting, on the bottom side, into grooves in the steel supporting bar, and, on the other, in grooves in the zinc or copper capping-piece. The system is suitable for all kinds of roofing, and enables curved roofs to be glazed with straight glass.

STANLEY BROTHERS, LTD.

Messrs. Stanley Brothers, Ltd., of Nuneaton, make a special object to produce good work. Their chimney pots—to be obtained in a variety of patterns—ridges, finials, and tiles are all well made and of good quality, and they are also of a very deep red colour. Glazed bricks of every kind can be procured from them, and their stand at the Exhibition showed the large selection available, and the manner in which one colour blended with another. Of these bricks the salt-glazed possess a perfectly smooth surface, while the grey ones give the wall the appearance of its being built in granite. Architects needing goods of best quality should apply to this firm.

ADAMS' PATENT SEWAGE LIFT CO.

The Adams' Patent Sewage Lift Co., engineers, of York and Westminster, showed, in addition to penstocks, flap valves, &c., their "Automat" apparatus for operating various types of bacteria beds and sewage filters. The timed siphons and supply apparatus controlled by air transmission, Mr. Adams' latest inventions, fulfil—variously arranged—every requirement for handling sewage, whether upon "contact beds" (Mr. Dibden's system) or for the distribution of sewage in spray or in bulk upon "continuous" filters. The principle chiefly employed is the air lock. This is formed within the interior of a siphonic apparatus by means of air displaced by rising liquid and transmitted through suitable pipes to the interior of the apparatus. The air lock thus formed stops the passage of liquid; its release again brings on the supply. For supplying filters on the "continuous" system, either in spray or bulk, the alternating siphons are specially useful. Placed in one chamber these discharge its liquid contents alternately to one or other of two filters, thus securing very long periods of rest for recuperation, which enables the filters to deal with a volume which would be otherwise impossible. The firm manufacture automatic apparatus for every description of sewage filter and sewer flushing work.

MILLARS' KARRI & JARRAH FORESTS, LTD.

Millars' well-known "Swan" brand Karri and Jarrah timbers undoubtedly are among the finest woods for street-paving, as owing to their toughness and closeness of grain they are practically non-absorbent and most durable, and being members of the eucalyptus family are antiseptic. The woods are used in almost every town of any dimensions in the kingdom. The address of Millars' Karri and Jarrah Forests, Ltd., is 72, Bishopsgate Street Within, E.C. Their mills at Purfleet, on the Thames, are capable of turning out a million blocks per week, and for the year ended December 31st, 1900, the Company's mills turned out the record quantity of 90,862 loads, equal to 54,517,200 ft. sup. 1in. thick. The woods are also used largely for sleepers, crossing and bridge timbers, harbour and pier works, and carriage and waggon building. Their great density renders them practically impervious to moisture, and no creosoting is necessary.

A. W. GREEN & CO.

Green's improved patent fireproof, sound-proof and ventilated floors are formed with hollow lintels and flat tiles, made from a mild tempered clay capable of sustaining a high temperature. No centering is required; the hollow lintels and flat tiles themselves constitute this, and the ceilings can be plastered immediately after fixing. The floors will sustain a safe working or live load of from 1 cwt. to 5 cwt. per ft. sup. The soffits of the hollow lintels and flat tiles are grooved so as to form a dovetail key for the plaster, but they can be had plain for places where a finished ceiling is not required, or glazed. The hollow lintels are slotted through at each end so as to bear upon the bottom flanges of the rolled steel joists, and thus protect them from exposure to fire. The address of Messrs. Green & Co. is 35, Gorst Road, Wandsworth Common, S.W.

ARMOURED CONCRETE CONSTRUCTION CO., LTD.

This firm, whose address is 5, Westminster Palace Gardens, Artillery Row, Westminster, are introducing armoured concrete construction, largely used on the Continent, into this country. Armoured concrete is formed by using iron, generally in the form of rods, in combination with Portland-cement concrete, which render the concrete capable of resisting enormous tensile stress. It is claimed that armoured concrete is from 15 to 20 per cent. less costly than iron and steel construction, strength for strength. The great advantages claimed for this system of construction are: great strength and stability, elasticity and pliancy, economy in construction, indestructibility, non-corrosion, costly painting dispensed with, architectural effectiveness and beauty of design. Under the patents of Messrs. Wayss & Freytag, contractors of Neustadt, Germany, this company also carry out concrete conduits for electric cables; such conduits are now exclusively adopted by the Imperial German Postal Authorities.

COX & YEMAN.

Messrs. Cox & Yeman, of 184, Brompton Road, S.W., exhibited at the Building Trades' Exhibition a very fine piece of oak wall-panelling, with chimney-piece and billiard-table, adapted from the original in the Victoria and Albert Museum from Bromley House, dated 1606. This at once showed that the firm are capable of executing work of the highest character, both as regards design and workmanship.

DAVIS & BENNETT.

Messrs. Davis & Bennett, of the Westminster Sanitary Works, Princes Mews, Great George Street, S.W., have a number of interesting specialities. One of these is a porcelain bath fitted with a copper sparge pipe over the rim, and a specially-arranged outlet. The chief features of the former are that the water issues all round the bath and thus washes the sides, at the same time warming the porcelain and so rendering it more agreeable to the bather. This bath, though fitted with 2in. waste pipe only, empties away rapidly and quietly. As regards water-closets, the firm manufacture all varieties, including one with an automatic seat action which starts the flush when the pressure on the seat is removed. Messrs. Davis & Bennett have executed work in a great number of large town and country houses, at leading clubs, and at many well-known hotels, theatres, hospitals, and factories.

New Companies.

Liverpool Academy of Arts (founded 1810, incorporated 1901).

Registered April 11th with fifty members, each liable for £1 1s. in the event of winding up, to promote art by the holding of exhibitions and schools, or otherwise. The management is vested in a council.

Armoured Concrete Construction Co., Ltd.

Registered April 12th to carry on the business of cement manufacturers and merchants, manufacturers of armoured and ordinary concrete, contractors, engineers, builders, &c. Capital £5,000 in £1 shares. The first directors are A. Johnston, F. Candy and H. C. Werner (managing director and secretary).

Thurmaston Brick Co., Ltd.

Registered April 16th to acquire and carry on the business of brick manufacturers heretofore carried on by Birkinshaw & Co., at Thurmaston, as the Thurmaston Brick Company. Capital £15,000 in £1 shares. The first directors are T. H. Heward, A. Barron and J. T. Bambury. Registered office: 68A, Humberton Gate. Leicester.

Bell's Synthetic Building Materials Co., Ltd.

Registered April 16th to acquire from H. Bell English patents Nos. 22,302 and 22,303 of 1900, to acquire any other patents, inventions, and rights, and to carry on the business of builders, contractors, timber merchants, engineers, dealers in building materials, &c. Capital £12,000 in £1 shares. The first directors are E. H. Bell, T. Frost and J. T. Szek. Registered office: 195, Hammersmith Road, W.

Moreton Brick and Tile Co., Ltd.

Registered April 17th to acquire lands buildings and hereditaments at or near Moreton, in the parish of Bidstone, or elsewhere, in the county of Chester, and to carry on the business of brick, tile, pipe, tube, chimney pot, sink, gully, trough, and cement manufacturers, clayworkers, &c. Capital £10,000 in £1 shares.

COMPLETE LIST OF CONTRACTS OPEN.

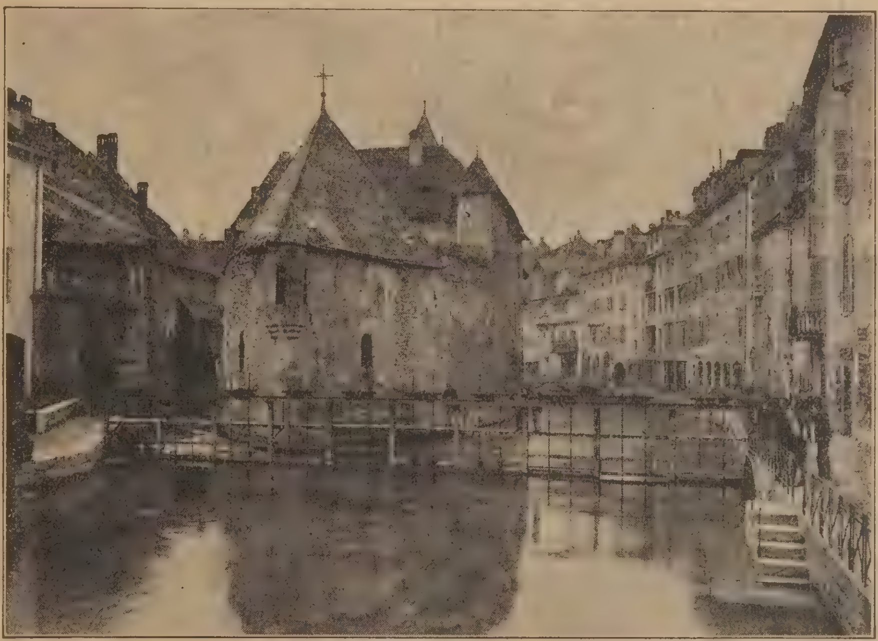
An Architectural Causerie.

Architecture at the Royal Academy. There is perhaps no other institution in this country which is so severely criticised as the Royal Academy. Those who are responsible for its management naturally attempt to vindicate its aims and methods, while those who have formed the conviction that the whole exhibition is a farce, groan out their pessimisms year after year, till we sicken to death of them. Some of these critics chiefly occupy themselves with comparisons between present and former exhibitions, always to the detriment of the present; others, imbued with the spirit of the Beaux-Arts and Montmatre, taunt us with generalities, and hold the gods of Paris before our eyes as *dii majorum gentium.* On the first Monday in May the public flocks in. The "superior" portion goes into raptures which are as artificial as the feverish exclamations of Mark Twain's pilgrims; the "ordinary people" are drawn by the pretty and the sentimental; but there is a residue of persons who can and do appreciate, who always find much to enjoy in every Academy, even though the "higher criticism" be hostile and very depressing. Whatever may be the opinion of the pictures at this year's Exhibition, we think all will agree that the Architectural Room is most disappointing; but we do not say this as the prelude to a dirge. There is a great deal that is mediocre, little, perhaps, that is really bad, but if this selection of 166 drawings—fewer than usual—is the best of the hundreds that were submitted, we are indeed sorry for the authors of the rejected drawings. Without a doubt the domestic work shown is by far the most pleasing, and some of the houses are delightfully conceived. One of the most interesting of these is the house at St. Albans, Hertfordshire, by Messrs. Cox & Silk (1642). The design savours of the old houses of the Cotswolds and is exceedingly neat in treatment; grey slates are used for the roof, with red chimneys, and though no plan is given, the main internal arrangements are, as they should be, manifest by the exterior. Two gabled wings jut out from the main building, in the centre of which is the entrance, while outbuildings are attached at each side, the whole effect being very quiet and restrained. "Glebelands," Wokingham, by Mr. Ernest Newton (1578), is another pleasing example of domestic architecture. The gables, slightly rounded at the top, are very characteristic. Mr. Newton's house at Chislehurst (1573) is not anything like so good. Mr. George H. Stevenson exhibits the "Cock" tavern at Kingsthorpe (1624). This tavern, with its steep roofs and quaint windows, has an old-world aspect, and, strange to say, does not need huge cut-glass lamps, decorated glass-panelled doors, and carved walnut fittings to make it beautiful. In the new house at Ascot Heath (1528) Mr. Leonard Stokes shows a clever arrangement of a verandah and conservatory, which are treated as integral portions of the design (the drawing, by the way, is in the style of Mr. Mallows, the method of putting in the close-cut hedges being especially familiar). Mr. Walter H. Brierley exhibits two drawings of Welburn Hall, Yorks. (1576 and 1613), which he has remodelled and added to, a loggia being very effectively treated. Some excellent etchings by Fred. Slocombe are shown of the house near Piccadilly by Mr. C. J. Harold Cooper (1591–1596 and 1597). Figures of children are introduced into the stair balustrade, but we would suggest that the two female figures at either side of the dining-room chimney-piece are altogether out of scale—being too large—the same remark applying to the figures in the frieze above. Oak panelling is used throughout this house, and the staircase leads down to the hall in the "grand" manner. Mr. James Strong's golf club-house at Forby (1645) and Mr. Arthur Stratton's "House on the Thames" (1598) are both above the average, a feature of the latter being a long verandah with gallery over. The absence of large sheets of plate glass is specially noticeable in all the houses mentioned, the windows being characterised by strong mullions and small panes, which are much more satisfactory in appearance. There are no private houses by Messrs. Brewill & Baily (who, however, show the Infants' School at Cresswell, Derbyshire, No. 1537, a clever piece of work), and Messrs. Bateman & Bateman have designed much better houses than that at Barnet Green, Worcestershire (1640). Mr. Arnold Mitchell also does not improve his reputation by the house at Bowden Green, Pangbourne (1631), and one was not particularly pleased with St. Aidan's Vicarage, Leeds, by Messrs. Bedford & Kitson (1636). We miss the work of Messrs. Niven & Wigglesworth. In concluding the notice of domestic work we may mention the view in the salon of the Château Mauricien, Wimereux, by Mr. Belcher (1599), a beautiful coloured drawing of work academic in character and very French in feeling; Mr. Bodley's "Hayes Lodge," Morley, Derbyshire (1647); "The Birchmoor Lodge," Woburn (1580), by Mr. H. Percy Adams; and a house at Matlock Bath, by Mr. T. Raffles Davison (1533). Mr. Basil Champneys' "House at Heathfield, Sussex" (1558), is not improved by the uneven treatment at the top of the bays, and "Huntercombe Manor," by Mr. Andrew J. Gordon (1678), looks as little like an Oxfordshire house as a French château would.



CHATEAU DE L'ILE, ANNECY. (See page 263.)

Coming now to municipal and business buildings, we find many competitive designs in the Architectural Room. Mr. Runtz exhibits a sketch design for the exterior of the new Gaiety Theatre and "Morning Post" offices (1560), and his Strand Improvement Scheme, as portrayed by Mr. Raffles Davison (1559); with regard to the latter, it is amusing to notice the ingenuity of the draughtsman, who, to show the buildings to best advantage, has conveniently omitted the church of St. Mary-le-Strand, allowing plenty of room for the royal carriage and troop of Lancers to pass by, and for the crowd on the pavement, which is, apparently, about 25ft. wide—very cunning this! Then there are the Swansea Dock Offices, Belfast Assembly Hall, the new Sessions House, Walsall Municipal Buildings, Blackburn Police Courts, the Cartwright Memorial Hall at Bradford and others—all more or less of interest, though generally less. Mr. Collcutt shows us again Lloyd's Register of Shipping (1563), and Mr. Aston Webb the sick-quarters for the Britannia Royal Naval College, Dartmouth (1620), and a detail of one bay of the Victoria and Albert Museum (1616), with Donatello and Qtn. Matsys under canopies. The new buildings for the University of Cambridge, by Mr. T. G. Jackson (1568), are very scholarly. They comprise the Sedgwick Memorial Museum of Geology, the "Squire" Law Library, Law School, and Archæological Museum. The Law Library occupies the centre, and is supported on three open arches, with five deep bay windows above: the whole is most effective. Mr. E. S. Prior's new medical laboratories at Netley (1542) are treated in red brick and stone, with a rusticated base pierced with small semi-circular barred windows, the effect being solid and compact. The same cannot be said of the design for Government offices at Zurich, by Mr. Alexander Koch (1536), which is of the "spiky" order, though it presents an effective sky-line. In "Hamilton House," on the Embankment (1582), Mr. William Emerson has the courage to use large expanses of plain wall surface, with good results, especially on the east and west facades; but the details of the windows—with curious mouldings, Indian in style—are not good. This building, however, is far better than his Royal Caledonian Orphan Asylum at Bushey (1584).

Several good churches are shown, particularly those of Mr. Bodley at Ecclestone and Chapel Allerton (1664 and 1654 respectively). Mr. E. B. Lamb is also very successful—his design for a national monument to British heroes (1664) shows a large central tower with spire, around which numerous turrets and buildings cluster, forming a pyramidical composition. Mr. Caröe is not seen to advantage—his Stoke Damerall Church, Devonport (1543), has a tower altogether restless and top-heavy. Of the remaining exhibits, the memorial bridge by Mr. Beresford Pite (1672) is very distinctive. This bridge has five arches, with a group of sculpture arranged across the bridge over three more arches, a colonnade extending at each side. Mr. Pite has made the drawing himself in his well-known manner. Mr. Hamo Thornycroft shows his design (1555) for a bronze canopy to form part of the Dean Colet Memorial to be erected at St. Paul's School, West Kensington. The canopy has slender floriated stems, with a corona filled with lettering, but the treatment is far from satisfactory. Mr. Halsey Ricardo exhibits the joint terminal station at Howrah, Calcutta (1588)—a clever design. This completes our notice. It will be seen that though there is much to interest, there is nothing of superlative merit, and many men of note—such as Mr. Norman Shaw, Mr. Wilson and Mr. Alfred Waterhouse—do not exhibit. Next week we shall deal with the sculpture.

SOME NORTH CORNWALL CHURCHES.—II.

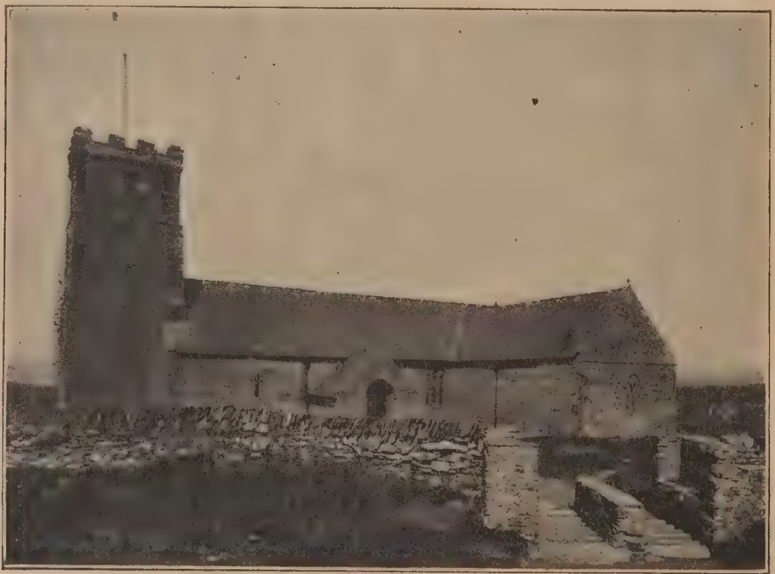
By FRANK BAINES.

(Concluded from p. 233 of No. CCCXXV.)

It is curious to find so many fragments of Norman work in and about the churches, and yet so rarely to meet a complete piece of Norman building. The arches on the north side of the nave of St. Minver are said to be Norman, but besides there being a very grave doubt as to the truth of this, there is little distinction about them. The most curious find I had in this way was coming across a vast Norman capital, set in one of the churches upright upon its necking, of undoubted Norman origin. The building, if any, to which it had belonged must have been six or eight times the size of the average Cornish church, but no further traces were to be found anywhere in the vicinity.

Mawgan will make its claim upon the admiration of the visitor in many ways. The church is literally embowered in lofty Cornish elms, that small-leafed variety which is met with so frequently about the hills and combes of this beautiful county.

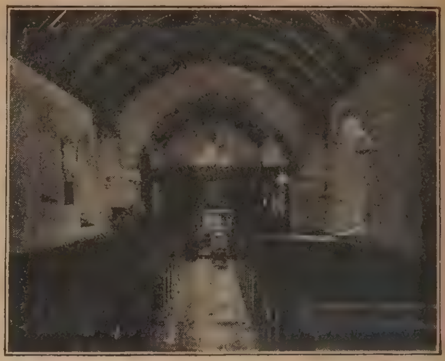
The church most unlike Mawgan in its sternness of situation, its cold aloofness from Nature in her softer aspects, is Tintagel. Standing upon an extreme headland, it overlooks all the coastline south to Pentire Point, and north past Bude and Bos to Hartland light, and far Lundy, set in the sea as a weather gauge. The church of St. Marcelliana, named from one of the nine saints who sailed miraculously from Ireland on a mill-stone, about the sixth century, stands upon the cliff west of the castle ruins. Although it was restored about 1870, two early Norman doorways remain almost untouched, one of which has a solid tympanum. It is built in the form of a cross without aisles, with Lady chapel and transepts considerably larger than is usual in Cornwall, and a solid circular Norman arch. The interior is very dark, and it seems as if the builders did not wish to give the uproarious elements one bit of advantage more than was essential. To be in this sombre building when a great west wind is beating in from the Atlantic, and the roar of the waters below comes up with the spray, is an experience to value. The church is full of interesting details, the Norman font on its four spreading legs being not the least among them. A curious recessed tomb is in the south wall, almost opposite the squint, the walls about which are much older than the main building and said to be Saxon. There are the remains of a carved screen, the tracery of which has been beaten out in places. It is fourteenth-century work, and almost black oak, very well preserved in the parts left. Within the vestry is an old stone altar, quaintly cut with five crosses, which is now evidently used as a robing table. The people at Tintagel appreciate the force of their storms, for even the tombstones are buttressed against them. Nothing grows here on the bare stone walls about the churchyard; only in between the leaning stones the long coarse trumpet grass flourishes with purple patches of the sea pink. There is no gate by which to enter the churchyard: a break in the wall merely serves its purpose, with bars of granite laid horizontally 6in. or 8in. apart with a cavity of 9in. or a foot deep in between. This is to prevent the sheep straying into the churchyard to graze, and acts as a real preventive. The church has one of the few good Cornish brasses of early fifteenth-century date, strongly lined, and in memory of one Johanna, whose lineaments it portrays. The church of Mawgan contains four or five very good brasses of fourteenth-, fifteenth- and sixteenth-century workmanship—one to the daughter of Sir John Arundel, whom, so runs the inscription, served five queens. In St. Columb Major are three more brasses, very well executed, and one that looks like foreign workmanship, laid to the memory of the same noble family.



TINTAGEL CHURCH.

A word must be said of Tintagel Castle, although its interest is mainly of the sentimental and picturesque. A weird wild look it has climbing up the steep hillside overlooking both bays and running right to the very verge of the sheer cliff edge. The towering pillar and crumbling column of King Arthur's seat is but the place of sea-birds now; no foot could reach its height since the seas have invaded it, as is shown by the landslip between it and the main cliff. The date can only be arrived at approximately, but it is put anterior to the Conquest; and in 1330 the castle was sufficiently of a ruin for its timbers to be taken down from the great hall.

About a mile and a half from Tintagel, driving inland, is a charming old house called Trethevy, near St. Knighton's Kieve and waterfall. Its window frames, door posts and lintels are of old carved oak taken from a stripped chapel near by. There were two benches built up of the same fragments, and Sir Henry Irving, visiting here prior to his production of King Arthur, bought one of them for the staging of that play. The chapel mentioned is now used as a cow-house; and if the visitor has enthusiasm enough to brave the terrors of accumulated droppings about the place, he will see a piscina above the troughs and quaint pointed windows without tracery, and a fourteenth-century arch circling above the backs of the cattle within. I should like to mention here the fine old farmhouse of Tresungas Barton as being the most interesting of all the countryside. It was built about 1250 and rebuilt in 1660. A square, low battlemented tower marks the entrance, with wings on either side. Unfortunately the left wing has had double-hung sashes put in place of the old windows, which were blocked up with stone to escape the window tax. The lights have not even yet been replaced in the top windows of the tower and some windows in the gable which juts out from the extreme end of the left wing. The building is much admired by its present holder, and great care has been taken to preserve it without effacement of any kind The rooms are large, with low wood ceilings, and all the windows, except the three double hung sashes, are twisted bulging leaded lights very heavily leaded, and quite weather-proof in spite of their age. There are signs to show that the building was originally much larger, the space now occupied by the rick and poultry yards and farm buildings being included within it. It was used by the smuggling community, earlier in its career, a boarded-up staircase leading to vaults which evidently served the purpose of secret storage. There are tales of an underground tunnel leading to the coast, but they are absolutely unauthenticated; yet there is little doubt that the original building saw stirring times. This farm is an excellent centre for the churches mentioned all round, many being within fair walking distance, and the remainder reached by drives through beautiful country by coast or inland roads.



TINTAGEL CHURCH.

The church of St. Minver is a landmark for miles, its tall well-proportioned spire rising into the view when all else of the church is hidden. This church is without a rival, for none other in North Cornwall has a spire to compete with it. The west tower is Early English, as is the main building, but the spire is of a much later date, having been blown down and rebuilt. There have been Perpendicular additions which have nothing striking about them. The points most in favour about the church are its cool ample proportion; its fresh sweet-coloured stone arches, which give a silver-gray tone to the whole of its interior; and its numerous bench ends. Many of these are remarkable for the strange working of ideas and quaint fantasy of design. The best of them are fronting one another in the nave. Here are to be seen weird beasts and birds, some of the wildest imagination, and most excellently preserved in the restoration of the building. The church was restored by Mr. Pier St. Aubyn, who has, indeed, restored many of the Cornish churches. It has been most thoughtfully carried out, with great care and taste, every effort being made to preserve intact the old work in its original position. This, Mr. St. Aubyn has not always been perfectly successful in, but the work at St. Minver and St. Columb Major is eminently so. Some of the bench ends have in time past been badly used; these are now made good by pieces fitted in where necessary, and both new and old left the natural colour of the wood, so it can be seen at a glance how far the old goes. Most of the roofs in Cornwall are of the cradle type, and St. Minver's is no exception; but very few of the old beams remain, and the original deeply-carved wall-plate has almost completely vanished. Behind the altar and beneath the tower are some deeply-incised slate slabs. This is common everywhere about the country, some reaching a great perfection in execution and design. Many are of late seventeenth-century style, and I was surprised to see set in the paving of St. George's Chapel, Windsor, a slate slab very similar to one seen in a Cornish church some years before. In the churchyards are to be seen slate slabs even undercut, and rather like high-relief wood carvings than cuttings in the slate; they are so finely carved as to be almost like a drawing upon the stone.

The church of St. Mabyn also calls attention to itself over miles of country—the tall tower appearing above the horizon from almost any point of view—the church itself standing upon high ground. The tower was badly damaged by lightning in 1865, and has consequently been restored, thus losing much of its attraction. Grotesque corbels terminate the angles of the tower, and four niches hold four quaint statues high up in it. The building is mostly Perpendicular, restored rather unsympathetically, yet there is some excellent detail to repay the visitor.

St. Columb Major is situated in the upper part of the lovely valley of Lanherne. The church, which was restored in 1867, is one of few examples of tall and graceful architecture in this part of Cornwall. It is of great size for the county, and even to the uninitiated is very beautiful. The piers and arches of nave, south-porch door, and window in south transept are all Early Decorated of a pure high character, as is also the font. The tower is the happiest expression of the Perpendicular to be seen in North Cornwall; the slight graceful buttresses rising tier by tier to the pinnacled corners of the battlements, and the admirable proportion, contrive to make it a perfect example in its way. It stands upon open arches on its north, south and west sides, the font almost beneath it having four strange grotesques cut on its sides with rolling protruding tongues. The beautiful window in the south transept has been barely touched in the restoration, and is a fine example of geometrical tracery. Many of the old roof-beams remain, and the moulded and carved wall-plate can be well seen from the floor of the nave. A very interesting stone altar was found prior to the restoration, under the floor, and has now been placed upon granite shafts within the chancel. This church contained an old pulpit, which, unfortunately falling into decay, has since been removed. It was much like one to be seen at St. Teath Church, richly carved and with rather a strange scheme of colour carried out upon it. By far the most interesting and striking pulpit of this part is to be seen in Mawgan church. An elaborately-carved cornice runs completely round its top, and a crowded carved moulding at the base. Between these are five panels, in which are carved the symbols of the Passion in high relief. They are very realistically rendered, and make an impression some distance off.

Many churches have been left without remark here—churches which would well repay an examination, yet an end must be made somewhere, and no more fittingly than at the charming church of St. Columb Major.

The striking interest of this North Cornwall architecture is its homeliness, its quiet partnership with the people, their life and the county It is really a part of Cornish history, which in itself is fascinating enough, but which in conjunction with the architecture is even more so. I should like to end with the words of the late Mr. J. D. Sedding. "The Cornish churches," he says, "are . . . to many full of a peculiar, inexpressible charm. These simple structures seem somehow to be part of the simple nature of the moor and down which surround them; they have what painters call quality or tone in them; they are essentially human, eloquent of the character of the men who reared them; and they are full of the silent poetry of an art that was religious while it was human, and that reflected far-reaching traditions while it was full of contemporary life and thought."

CHURCH OF ST. MINVER, NORTH CORNWALL,

TESTS WITH FIRE-RESISTING MATERIALS.*

A SUMMARY OF THE BRITISH FIRE PREVENTION COMMITTEE'S WORK.

By ELLIS MARSLAND.

BY the kind permission of the executive of the British Fire Prevention Committee, I am enabled to give you some account of the tests and experiments with fire-resisting materials conducted by them, in the hope that they may be of interest to those engaged in building operations and to those who take or have any interest in preventing the spread of fire.

The work of the Committee, so far as it has been undertaken, may be divided under four heads:—

(1) Experimental test with floors, commencing with simple forms of construction deemed to be fire-resisting only, and proceeding to more complex forms deemed to be fireproof.

(2) Experimental tests with fire-resisting partitions of various construction.

(3) Experimental tests with doors of various constructions, both of wood and iron, or a combination of both.

(4) Experimental tests with protective coverings to openings and methods of glazings which in themselves form a protection against fire. This last is a very important factor in dealing with fire-prevention, as, however fire-resisting a building may be in itself, unless it can resist fire from the outside it is as liable to destruction as the most inflammable building.

In commenting upon the different forms of construction and their behaviour under the fire tests to which they were submitted, I do not propose to mention any names, for reasons that may be sufficiently obvious, but shall merely differentiate between the test initiated by the Committee and those submitted for test by manufacturers; any further information is to be obtained in the official published reports.

For the information of those who are not familiar with the system and plant employed by the Committee, I may say that the tests are conducted in a block of brick huts about 10ft. square inside and others 10ft. by 22ft. 3in. The method of producing the heat is by a gas generator, and the gas is conducted to the several chambers by cast-iron pipes. The record of the temperatures attained in the chambers is taken by means of electrical pyrometers, similar to those used in the Royal Mint.

A Test with an Ordinary Floor.

Starting with experimental tests with floors, the first to which I shall direct your notice is an ordinary floor with deal joists, the soffit of which was protected by plaster, termed asbestic plaster. This was applied on ordinary wood lathing, and the thickness of the plaster after completion was about 1⅛in. On drying this reduced itself to about ⅞in., and during the process of drying cracks developed over the surface. Before the test these were stopped. The test lasted forty-five minutes, the temperature gradually rising from 500 degs. to 1,500 degs. Fahr. The summary of effect is as follows: No perceptible difference in the ceiling was observed during the progress of the test. The application of water caused no injury to the ceiling. No portion of the ceiling fell either during or after the test. When examined after the test cracks had developed over the surface, and some of the wood laths were charred, but none had ignited. This test may be considered satisfactory, as the object was attained, namely, to render the floor fire-resisting for forty-five minutes, which would under ordinary circumstances, have allowed th, occupants in the rooms over to have escaped.

A Similar Floor Protected with Slag Wool.

The next test is of a similar nature. The floor was of ordinary joists and boarding, but the protecting material to the soffit was slag wool 1¾in. thick. This was secured with screws to the soffit of the joists and a ⅜in. matchboarded ceiling was placed under the slag wool. The testee decided to have a test of an hour's duration, with a gradually increasing temperature to 1,800 degs. The summary of effect was as follows: At the conclusion of the test the flooring on top was, so far as could be seen, uninjured, and when the joists were examined they were sound. The boarded ceiling had, of course, disappeared, but the slag wool remained in position and had protected the floor. A good deal of heat was retained in the floor, and at one point, where water had not been applied, a small hole was burnt in the flooring about three hours after the test was concluded. This test may also be considered satisfactory, as it retarded the spread of the fire for at least an hour.

A Floor with Baulks of Timber Side by Side.

We now come to a test of an interesting nature as showing the fire-resisting qualities of simple baulks of timber laid side by side, any spaces between being filled with fireclay grout, the soffit not being protected in any way; the thickness of the baulks was 9in. This was the Committee's own test, and it was decided to have an eighty minutes' one, the temperature gradually rising to 2,000 degs. Fahr. The result was that the under-surface of the wood beams was charred to an average depth of about 2in., but beyond this no damage was done. The test clearly demonstrates what fire-resistance there is in such a floor, but it must be carefully borne in mind that no space must be left between the timbers that is unfilled by the grouting, otherwise the fire draws up through and spreads to the next floor.

Section 74 of the London Building Act provides that, in premises exceeding 1,000 sq. ft. in area and used partly for purposes of trade and partly as a dwelling-house, the part used for purposes of trade shall be separated from the part used as a dwelling-house by floors and walls of fire-resisting materials. This does not of course imply that the floor is to be fireproof, but the floor is to be sufficiently fire-resisting to prevent the spread of fire at least for a reasonable time, to give an opportunity for the inmates above to escape. And in the schedule of materials deemed to be fire-resisting concrete filled in between joists of floor is included.

Test with a Floor of Wood Joists and Concrete.

The Committee thought that a test in this direction would be of considerable interest, and yield some useful information. Accordingly they made preparations for the simplest interpretation of the section, and arranged a test. With 7in. by 2in. joists, ⅞in. flooring, coke-breeze and Portland-cement concrete, 5 to 1,

---

* A paper read before the Society of Architects on April 25th, 1901.

CHURCH OF ST. COLUMB MAJOR, NORTH CORNWALL.

filled in between the joists to a depth of 5in., and kept in position by 1in. by ¾in. fillets nailed to the sides of joists 2in. from the bottom, a ceiling was nailed on to the soffit formed of ⅝in. matchboarding. The time decided for the test was seventy-five minutes, commencing with a temperature of 500 degs. and increasing to not more than 2,300 degs. The floor also was to be loaded with 100lb. per sq. ft. distributed. The result of the test far exceeded the Committee's expectations; it was not till after eighty-two minutes that the floor collapsed. The summary of effect is as follows: In fifteen minutes all the boarding to the soffit was consumed; in fifty-four minutes flame came through the floor between the last joist and the wall.

I should like to point out here what an important part the 1in. by ¾in. fillets played in the construction of the floor in preventing the fire getting through, and it was in consequence of the fillets being omitted on the outer side of the two end joists that the flame came through there, and these joists were the most damaged.

The concrete between the two east joists fell out in seventy-four minutes; meanwhile the fire had been gradually eating its way up the other joists from 2in. to 2½in.; being thus reduced from 7in. to 5in., or 4½in., they could no longer sustain the weight of 100lb. per sq. ft., and the floor and load collapsed in eighty-two minutes. This was a very severe test for so light a floor, and I think you will admit that it stood it bravely. The floor boards were not burnt, but only blackened by the smoke.

Another Wood and Concrete Floor Test.

A test of a somewhat similar character to the one just mentioned was instituted to discover the fire-resisting qualities of different descriptions of concrete. This floor was constructed of 3in. by 9in. deal joists spaced 16½in. centre to centre, which gave seven bays. Two of these bays were filled in to the full depth of the joists with coke-breeze and cement-concrete, 6 to 1. The next two bays were filled in with pit ballast and cement-concrete, 6 to 1, and the remaining three bays were filled in with concrete composed of pit ballast 3 parts, coke-breeze 3 parts, and cement 1 part. The concrete was supported between the joists by 1½in. by ⅞in. fillets. The soffit of the ceiling was plastered render float and set, and ⅞in. flooring was nailed on top of the joists to complete the floor. It was decided to test this floor for one hour and a half to a gradually increased temperature up to 2,500 degs. Fahr., and then to apply a stream of water for four minutes. The summary of the test was that after a few minutes the plaster of the ceiling began to fall, whereupon the lower edges of the joists became ignited and gradually burned upwards. At the conclusion, the whole soffit of the floor was seen to be fully incandescent, particularly that in the coke-breeze and cement bays. On the application of water the soffit of the ballast and cement-concrete and the ballast-breeze and cement-concrete immediately disintegrated, and about 3in. in depth of it fell. The coke-breeze and cement alone was not affected. The floor remained in position at the conclusion of the test, but appeared seriously weakened and deflected.

It is to be regretted that it did not remain in position sufficiently long to be photographed, but after a test of this description a good deal of latent heat remains in the materials, and the joists being of combustible material continued to smoulder, the result was the collapse of the floor five hours after the test. On examining the remains the joists were found to be burnt through from 2in. to 6in. deep, and tapering to a further depth at the ends. The boarding was found to be slightly charred on the underside and at the joists, but otherwise was sound.

It could not be said the fire had passed through the floor, although smoke came through, and I think the floor may be considered a fire stop, although the weight of the concrete caused the collapse of the floor, and might constitute a source of danger on that account.

The behaviour of the ballast-concrete shows it an undesirable material for fire-resistance, while coke-breeze has many advantages. I might add here that, from my observation of the tests conducted by the Committee, it is the more porous and light of the incombustible materials that are the most fire-resisting.

Floor with Expanded Metal Ceiling.

The experience gained by the last two tests paved the way to the next; both the previous tests had shown that if the soffit of the joists had had further protection the fire-resistance of the floor would have been greater, consequently a test was arranged with an expanded metal ceiling suspended 2in. below the bottom of the 7in. by 2in. wooden joists, which formed a centering for the concrete as well as a key for the plaster. The concrete below the joists was of dry ashes and Portland cement, and that between the joists was composed of coke-breeze 3 parts, dry ashes 2 parts, and Portland cement 1 part. The test was arranged for two hours, which is the longest time yet given for a floor formed partly of combustible material. The temperature was not to exceed 2,300 degs. Fahr., and to be followed by a stream of water for two minutes. The floor also was to be loaded with 100lb. per ft. distributed.

The summary of effect is very short: In twenty-eight minutes plaster began to fall in patches from the ceiling, and continued to fall at intervals till the end of the test, when water was applied and further plaster was washed away. No other effect of the fire was noticeable, and at the conclusion of the test the floor was intact and carried its load. This floor did not subsequently collapse, although it smouldered all night. It was found that all the joists had been more or less damaged by the fire smouldering all night; portions of them were quite consumed, leaving the matrix only in the concrete. The least damaged of the nine joists forming the floor was the centre one, which was intact but for a piece about 12in. long and 5in. deep, which was consumed about 15in. distant from the south end.

This irregular consumption of the joists I am inclined to think was due to the difficulty of so filling in the concrete on the soffit of the joists as to form a complete protection; the vertical strips of expanded metal which carried the horizontal portion conducted the heat up the joists, and appeared a source of weakness so far as the fire-resistance was concerned.

Floor with Terra-Cotta Wired Lathing.

The next test, which was submitted by a manufacturer, deals with a floor supported by 9in. by 3in. wooden joists with a terra-cotta wired lath suspended ceiling, an air-space between the ceiling, and the concrete filling between the joists. The lathing was spread over the top of the joists, and depressed in the centre to the shape of an inverted arch; upon this the concrete was placed to a depth of 7in. in the centre, which when levelled brought it 2in. thick over the top of the joists. The concrete was of Portland cement and washed sand, in the proportion of 1 yd. of sand to two bags of cement. The suspended ceiling was formed of terra-cotta wired lathing secured to iron rods fixed to the soffit of joists with iron hooks. Ordinary three-coat work was applied to the lathing, but a proportion of plaster-of-Paris was incorporated with the material. The thickness of the plastering was 1⅛in. The test was arranged for one hour and a quarter, the temperature was not to exceed 2,000 degs. Fahr., and the floor was to be loaded with 56lb. per ft. distributed.

The summary of the effect was that a considerable portion of the plaster ceiling fell during the test, some of the lathing being bare before the test closed. The floor cracked at each side to the extent of ½in., and dropped ¼in. When water was applied, smoke, steam and sparks came through the cracks in the top of the floor. One of the joists carrying the ceiling was entirely destroyed, two partially so, and one though discoloured was practically sound. This floor did not collapse, but its supports were practically destroyed; it trusted for its fire-resistance to the suspended ceiling on the terra-cotta wired lathing and air-space, but after the ceiling was pierced, the heat had full play around three sides of the deal joists, and so brought about its ruin. A floor of similar construction, but with iron supports, will be mentioned later.

Fireproof Floor.

We now come to floors having pretentions to be fireproof, *i.e.*, the constructional parts of the floor are of non-combustible material. The Committee started with a simple iron and concrete floor, the soffits of the iron joists forming the floor being exposed. The Committee were somewhat criticised for instituting this test, as being a useless one, the result of which was already known. But I think the Committee were perfectly right in having it: firstly, because it is a very common form of fireproof floor, and, secondly, it gave the Committee data from which to start in showing by comparison the advantage to be derived in protecting or encasing the ironwork. The floor was constructed of 5in. by 4½in. steel joists placed 2ft. 6in. apart, and filled in with coke-breeze and Portland-cement concrete 5 to 1. It was loaded with 168lb. per ft. distributed. It was proposed to test this floor for two hours and a half up to a temperature of 2,300 degs. Fahr., but after one hour and twenty-five minutes, and at a temperature of 1,650 degs., the bulk of the concrete in the two outer bays collapsed owing to the deflection of the steel joists. The floor began to deflect after twenty minutes at a temperature of 1,200 degs., and a maximum deflection of 10½in. was recorded in one of the joists. The coke-breeze concrete was but little deteriorated. The disadvantage of filling in concrete between joists is in setting up and striking the centering and the attendant obstruction to the progress of the works by the supports.

Corrugated-Iron Centering.

The Committee instituted the following test in which corrugated iron filled in between the iron joists was the centering employed, the coke-breeze and cement concrete, 5 to 1. filled in on top. The soffit of the joists and corrugated-iron centering was protected by 2in. by 3in. deal ceiling joists suspended from the joists, and wire netting, ½in. mesh, was used as lathing and a plaster ceiling, three-coat work, applied; 1in. floor boards were nailed to the breeze-concrete on top, the floor and ceiling having a total thickness of about 12in. The floor was loaded with 158lb. per sq. ft. distributed. The test was to last one hour and a quarter and the temperature to be 2,000 degs. Fahr. In half an hour the ceiling began to fall, and in one hour the ceiling and ceiling joists had all fallen. At the conclusion of the test the soffit of the iron joists and corrugated-iron centering were observed to be red-hot, and the joists had deflected about 2¾in., but on cooling returned to within 1in. of level. The fire did not pass through the floor, but perhaps the test was hardly sufficiently long to enable a comparison with the former floor to be made, but certainly the deflection of the joists was not so great, and the floor would have been more serviceable without reconstruction, which the former floor would have not.

Floor with Expanded Metal as Centering.

The next floor is one in which expanded metal forms a centering as well as lathing. The construction of the floor was by iron joists 4ft. 9½in. apart, on the top of which the expanded metal is stretched and 3in. of furnace ash and Portland-cement concrete laid and finished on top with ½in. of cement and sand. The joists are protected with a suspended ceiling of expanded metal and ordinary plastering applied. The space between the floor and ceiling was ventilated by means of holes in the walls of the chamber. The floor was loaded 140lb. per ft. distributed. The test was to last one hour and fifteen minutes, and the maximum temperature was to be 2,000 degs. Fahr. The result was that during this time the fire did not pass through the floor. The plaster ceiling remained intact until the application of water, when some of it was washed away. There was a slight deflection of the floor and ceiling. It is to be observed that considerable advantage was gained by the space for ventilation, which in practice is not always obtainable.

Terra-cotta Wired Lathing for Centering and Ceiling.

We now come to the floor to which I before alluded, and it is on the same principle, but steel joists are substituted for the wooden ones. Terra-cotta wired lathing is used both for the centering and ceiling. The test was to be of 1¼ hours' duration and the temperature was not to exceed 2,000 degs., and the load 1½ cwt. per sq. ft. distributed. The result was the fire did not pass through the floor, but on water being applied some of the plastering was washed from the lathing. So little was the floor damaged that the testee decided to re-plaster the ceiling, and the test was renewed at a subsequent date, when practically the same results were observed.

The Last Floor Test.

The last floor test to which I invite your attention is one of 2½ hours. The floor was constructed of iron and concrete in which all the ironwork was embedded. The steel joists are spaced 6ft. apart, over which are placed stirrups to receive the bridging bars spaced 20in. apart. A slab of concrete is suspended to the soffit of girder, and a wood centering is necessary for filling in the concrete which is composed of clinkers broken small, sand and Portland cement, in the proportion of 4 parts clinkers, 2 parts sand and 1 part Portland cement. The concrete was 4in. thick, and a further depth of coke-breeze and Portland-cement concrete, 2in. thick, was filled in on top of this between the floor strips; the soffit of the floor and the sides and soffits of the steel joists were rendered in plaster three coats. The summary of this test is thus recorded: The plaster on the underside of the ceiling and around the beams cracked slightly before the application of water. On the application of water some of the plaster fell off the soffit of the ceiling and beams. The concrete forming the floor was not damaged. That enclosing the beams was slightly damaged and cracked. The fire did not pass through the floor. The wood strips bedded in upper surface of the concrete were uninjured. The test of this floor was a severe one, but not too severe for a fireproof floor, as any floor professing these qualifications should be at least able to stand a 2½ hours' test, otherwise it could only rank as fire-resisting. It should also be able, after serving as a fire stop, to be repaired and made good without reconstruction.

Tests with Partitions.

I will now pass to a short series of tests with partitions. It was necessary that the Committee should first obtain some data as to the fire-resisting qualities of the ordinary kind of partition used in buildings, namely, the lath and plaster partition with wood laths, the same with wire lathing, and the brick-nogged partition with bricks laid flat and also on edge.

This series was tested together, and the partitions were arranged with a passage 2ft. 4in. wide formed in the centre of a hut, and the partitions of the four different classes built on each side, the fire being arranged on one side of the partitions only.

CHURCH OF ST. COLUMB MAJOR, NORTH CORNWALL.

The summary of the test is thus recorded: The lath and plaster partition on the right was practically destroyed. Fire broke through the portion with the wood lathing in twenty-eight minutes at a temperature of about 1,600 degs. Fahr., and through that on the wire lath in forty minutes at about 1,750 degs. Fahr. The brick-nogged partition resisted the passage of the fire for the hour, although the plastering was disintegrated and studs charred at a temperature of 2,000 degs. Fahr.

A partition may be made fire-resisting in various ways. It may be constructed of combustible material and be packed with incombustible material like brick or slag wool. It may be constructed of combustible material, and such material may be made chemically fire-resisting. It may be constructed wholly of incombustible material. I am enabled to give you the result of tests with each of these forms of construction.

A Stud Partition protected with Slag Wool.

The first of these is with an ordinary stud partition, matchboarded on both sides and packed between the two thicknesses with slag wool. The testee desired a forty-five minutes' test and a maximum temperature of 1,800 degs. Fahr., followed by the application of water for one minute on the outside and two minutes on the inside. The summary of the test is thus recorded: The internal boarding was completely destroyed. The slag wool was fused and blackened on the inside face, and a narrow strip down the side of each stud was blackened. The studs were burned down ¾in. deep. The wire netting was sound. The studs were sound, white and clean for a distance of 2¾in. The outside boarding was sound, white and clean. both on the fire and passage, and the fire did not pass through the partition. Thus the partition formed an effective fire stop for a period at least of forty-five minutes.

Two Stud Partitions Tested Together.

The next is a comparative test between an ordinary stud partition, match-lined on both sides, painted with oil colour, and a similar partition with chemically-treated wood, and painted with a chemically-prepared paint to assist its fire-resistance. Fire was to be applied to one side of the partition and at one point for a period of forty-five minutes. On the other side of the partition some furniture and hangings were placed. The partitions and furniture were identical so far as construction was concerned, and the tests were started simultaneously in both huts.

Dealing with the non-treated wood first, the summary of the result is as follows: In three minutes smoke appeared in the interior of the chamber. In fifteen minutes sparks appeared in the chamber over top of door. In sixteen minutes flame over top of door caught muslin hangings. In thirty minutes fire all along top of partition. In thirty and half minutes the furniture began to burn; and in thirty-two minutes everything was blazing freely, and the whole chamber was full of flame. In forty-five minutes everything was consumed except the studs, which were blazing freely.

The result of the chemically-treated partition and furniture is as follows: In twenty minutes the chamber was full of smoke, with offensive smell. In twenty-nine minutes two lower boards of partition buckled near the gas flame. In forty minutes charred pieces falling from partition in passage. In forty-five minutes wood flaming in third board from bottom over third stud from east wall in passage. At the close of the test the chamber was entered and the furniture, curtains, &c., were found intact and unaffected except at the east end, where they were scorched by the burning timber roof of hut. At no time during the test did the temperature exceed 100 degs. Fahr. The result of the test is sufficiently obvious to need no further remark.

A Partition of Terra-Cotta Wired Lathing.

The next and following tests are all with partitions formed of incombustible materials. This partition was formed of terra-cotta wired lathing, fixed to the floor and ceiling, and covered with three coats of plastering on each side, in which plaster-of-Paris was incorporated. The partition when finished was 2½in. thick. The testee desired a test of one hour and fifteen minutes, and a maximum temperature of 2,000 degs. Fahr. The summary of the result is thus recorded: A portion of the setting coat on the fire side of the partition fell during the application of heat. Hair cracks, from which steam issued, appeared from time to time on the passage side of the partition. On the application of water on the fire side of the partition a considerable portion of the setting coat was washed off. The temperature of the outside face of the partition during the latter part of the test was too hot to bear the hand, although not sufficient to ignite a vesta by contact. The fire did not pass through the partition. It will thus be seen that, as a fire stop, for one hour and fifteen minutes the partition answered its purpose.

Steel Lathing.

A partition on similar lines, *i.e.*, plaster on both sides of a lathing medium, is the next which I wish to describe. The lathing medium was of steel sheeting, No. 28 gauge, and formed into dovetailed corrugations, fitted into **H**-section standards. The plaster was of ordinary material mixed with plaster-of-Paris, three coats on each side, the total thickness when finished being 2in. The testee desired a test of one hour and fifteen minutes with a maximum temperature of 2,000 degs. Fahr. The result of this test is thus recorded: Hair cracks, from which the steam escaped, appeared from time to time on the passage side of the partition. The temperature of the outside face of the partition during the latter part of the test was too hot to bear the hand, and paper held against it was scorched. The fire did not pass through the partition during the one hour and fourteen minutes it was applied.

Two Partitions Built up of Slabs.

The last two partitions to which I shall allude are built up in slabs. The first is in slabs about 1ft. 2in. by 8in. and 3¼in. Each slab has two circular holes 1⅝in. diameter running horizontally through it; the slabs were jointed in hydraulic lime and sand mortar, the joints of the slabs on the fire side were raked out and pointed in fireclay, and the whole surface was covered with a thin coating of the same material. The composition of the slabs is thus described: A mixture, by means of water, of plaster, hydraulic lime, some sort of neutral material, such as coke, sand, &c., and fireproof material such as asbestos with an addition of sulphuric acid. The result is thus recorded: A portion of the coating of fireclay on the fire side of the partition fell off on the application of water, as also most of the fireclay pointing to the joints. In no place had the fire passed through the partition. This partition for the sixty minutes of the test certainly acted as an effective fire stop.

The other partition was composed of slabs 4ft. 10½in. long, 10in. wide and 2¾in. thick; one face was fair and the other keyed for plaster. The slabs, according to the maker, were made of plaster with cocoanut fibre, cork dust and reeds embedded therein, and running horizontally along the whole length. There were from thirty to forty reeds in each slab. The slabs were set in mortar composed of two parts plaster-of-Paris, one part of lime and two parts of sand, and the vertical joints were grouted in with the same material. The inside of the partition was plastered in two coats, the ordinary materials being mixed with plaster-of-Paris, and the outside was skimmed over with one coat of lime, putty and plaster-of-Paris in equal proportions. The testee desired a test of one hour and a quarter with a maximum temperature of 2,000 degs. Fahr. The result of the test is thus recorded: The setting coat on the fire side of the partition fell during the application of heat. A portion of the rendering on the fire side fell on the application of water. The fire did not pass through the partition. No effects of the fire were apparent on the passage side of the partition, except two blisters and some hair cracks following the courses of the joints. The temperature on the outside face of the partition at no time exceeded 125 degs. Fahr. The plastering on the inner face of the partition was cracked and disintegrated. On examination after the test, the face of the slabs next the fire was found disintegrated to a depth of about ¾in., the remainder of the slabs being unaffected. This partition, then, may be classed as a fire-stop for at least seventy-five minutes.

Fire Tests with Doors.

I now come to a very interesting series of tests with doors of various constructions and various materials. The Committee were led to undertake this series with the view of ascertaining the length of time a door required under section 74 of the London Building Act would act as a fire stop. The section runs: "Provided that there may be constructed in the walls of such staircases and passages such doorways as are necessary for communication between the different parts of the building, and there may be formed in any walls of such building openings fitted with fire-resisting doors." On turning to the schedule of materials deemed to be fire-resisting, we find in the case of doors, oak or teak or other hard timber not less than 2in. thick.

For the purposes of comparison it became necessary to first of all ascertain the resistance of any ordinary deal door, and then of a solid 2in. door of the same material. These tests are made more interesting as the Committee were enabled to take photographic records of the outside of the several doors during the progress of the tests.

A Ledged Door and a Four-panel Door.

The first of the tests is that of an ordinary 1in. ledged door and a 2in. four-panel moulded both sides door, with panels ⅝in. thick; they were fitted into the recessed wall, built about 14in. back across the hut, one side of the door being in the chamber and the other side exposed to the external air. This arrangement was identical for all the tests, so that a separate description of the size and position of each door will be unnecessary. After twenty-five minutes the doors were practically destroyed.

Following upon this are two 2in. bead butt both sides doors, with 2in. solid panels. One was of deal and the other pitch-pine. In seventeen minutes flame appeared over the top of the deal door, and in twenty minutes over the top of the pitch-pine one. After fifty-five minutes, the doors were almost consumed.

Oak and Teak Doors.

We now come to the hardwood doors which are to be the fire stop. A test was made with a 2in. door as previously described of American oak, and one of Moulmein teak. After thirty minutes' test the condition on the outside was thus: The fire came over the top of the teak door in seven minutes, but it did not appear over the top of the oak one for thirty-five minutes; in fifty-five minutes the doors were practically destroyed. It should be pointed out that it is very desirable that the doors should fit as closely as practicable: the reason for the flame coming over the top of the teak door so soon was in consequence of it not fitting closely to the frame. Another teak door of similar construction, but somewhat thinner and with the panels in two thicknesses, will be dealt with later on, when the first appearance of flame was after eighteen minutes.

Doors of Austrian Oak and American Walnut.

The next two doors are of Austrian oak and American walnut; the flame did not come over the top of the oak door till thirty-three minutes after the fire was started, but in the walnut door flame appeared at intervals after fifteen minutes. After fifty minutes, the oak door had had the worst of it.

The last doors tested in this series were of Honduras mahogany and poplar. The fire came over the top of the poplar door in three minutes and over the top of the mahogany one in ten minutes. The condition of the doors after thirty minutes was thus: The poplar door had all the upper part consumed. It had all disappeared in forty minutes, and a temporary door had to be fixed in its place to continue the test of the mahogany door, which collapsed at fifty minutes.

These two doors did not stand so well as the deal and pitch-pine ones, although in justice to the poplar door it had somewhat warped away from the frame at the top and greatly facilitated the flame coming over and its consequent rapid consumption.

Doors of Three Thicknesses.

The Committee's experience with this series of doors led them to experiment with doors made of material in three thicknesses, and two doors were made, one of deal and the other of pine. The material was in three thicknesses, the two outer faces being vertical and the inner one horizontal. The boards were in about 6in. widths, and securely nailed together with 3in. clasp nails and clinched on the outside; the total thickness was 2⅝in. Each door was hung with one pair of strap hinges 2ft. 6in. long into brick rebates, and before the doors were put in position the rebates were screeded so that the doors should fit as close to the rebates as possible. These doors stood a longer test than the former series. Flame was not seen through the pine door till sixty minutes, although in the deal door flame came through in thirty-nine minutes. The destruction of the doors was very rapid after the fire came through, and at sixty-five minutes the test was concluded. The iron was the ruin of the doors, as when the nails and bolts became red hot they charred the timber around them and allowed the fire to come through.

Doors in Three Thicknesses Secured by Pins.

This led the Committee to test three doors of similar construction to the last, *i.e.*, in three thicknesses, but the thicknesses were secured together by ⅜in. double wedge-shaped pins, driven in from both sides, instead of clasp nails. These doors had frames, and the frames were splay rebated. The three doors were respectively of deal, teak and oak. The test with these doors gave the best results of any of the previously tested fire-resisting doors.

The deal door of this construction was tested against a four-panelled teak door, with the result that at the end of sixty minutes the teak door was almost consumed, but the deal door was practically intact as a fire stop, and at sixty-five minutes presented a good appearance while the teak door was all gone. The oak and teak door of the same construction as the deal door were still in position after seventy-five minutes, the teak one being the better of the two.

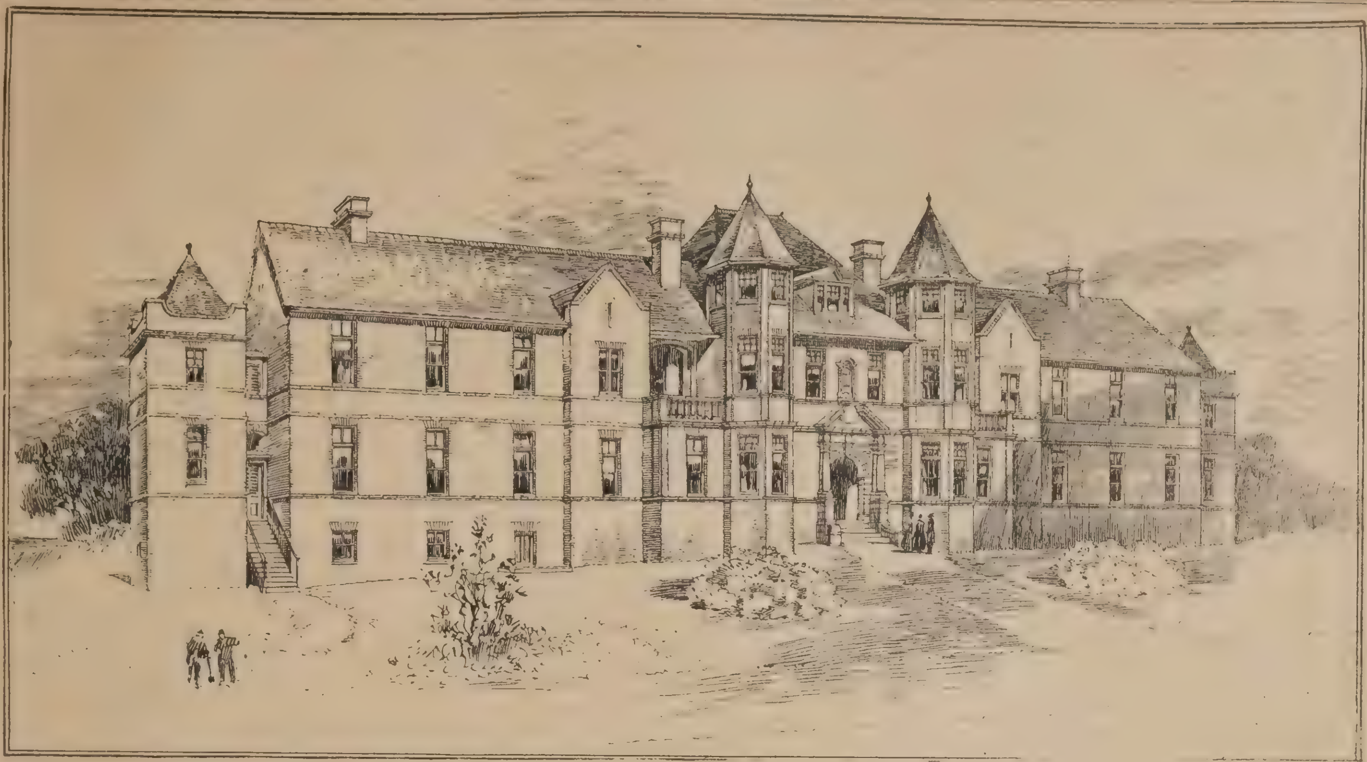
An Armoured Door.

This ends the series of tests with fire-resisting doors, and we come now to a comparative test with an iron door meeting the requirements of the Building Act under section 77, and a door constructed of wood and encased with tinned steel sheets, lock jointed and screw nailed. The test was to be one hour, and the summary is as follows: The wood door covered with tinned steel plates remained in position, but was much buckled and bulged, and the upper part gradually inclined inwards to a considerable extent, permitting the passage of flame. The first spurt of flame over the top of door was seen after five minutes. The iron-framed and panelled door remained in position, but became red hot, buckled and warped considerably, together with its rebated frame. The upper corner on the lock side gradually inclined inwards to a considerable extent, permitting the passage of flame. The first spurt of flame between door and frame was seen after twenty minutes. Notwithstanding that the iron door buckled, I am of opinion it is the best fireproof door at present in use, but to be effective it requires three hinges and three bolts, and the tendency to buckle is thus hindered. At a big fire recently I had the opportunity of observing the behaviour of a pair of doors fastened with three bolts, and the result was that while the building on the fire side was entirely destroyed, the iron doors prevented the flame spreading to the adjoining section.

Protective Coverings for Windows.

Under the fourth head of my subject I now come to protective coverings to windows or forms of glazing which in themselves resist at least for some time the action of fire.

For purposes of comparison the Committee instituted a test to arrive at the time the ordinary methods of glazing succumb to the action of fire. Three casements of teak were set up in a hut upon a dwarf wall; one casement was glazed with lead lights, one with ¼in. thick plate glass, and one with 32oz. sheet glass. Within six minutes flame burst through the 32oz. sheet-glass casement, and half the sheet had fallen. The other half fell within twelve and a half minutes. Within seven minutes the lead glazing had collapsed. Within twelve minutes flame burst through the ¼in. plate casement, and within fourteen minutes the whole sheet had



DORKING INFIRMARY. H. PERCY ADAMS, ARCHITECT. EXHIBITED AT THIS YEAR'S ROYAL ACADEMY.

fallen. The highest temperature was about 1,500 degs. Fahr.

A Test with Three Teak Casements.

The Committee had submitted for test three teak casements similar to the last, but glazed with copper electro-glazed sheets of prismatic glass in 4in. squares and $\frac{3}{16}$in. thick. The testee desired a thirty minutes' test with a temperature gradually rising to 1,000 degs. Fahr. Water was to be turned on to the outside of the glass for a period of two minutes at the expiration of fifteen minutes, and at the expiration of a further period of fifteen minutes water was to be applied on the inside for three minutes. The result of the test is thus recorded: After twelve minutes the whole of the glazing commenced to bulge inwards to the extent of 1in., 1½in. and 2½in. respectively. After twenty-one minutes the top portion of the centre casement sagged and left a space between the glazing and the teak frame; 317 squares out of a total of 324 withstood the action of the fire and water, and except for stars and cracks, the remaining seven squares were broken and had pieces out.

A further test on the same lines was undertaken, with the difference that the glazing was with small sheets of plate glass 4in. by 4in. by $\frac{3}{16}$in. thick, copper electro-glazed. The test was to be for forty-five minutes, with a temperature of 1,300 degs. Water was to be applied for two minutes on the outside at the expiration of twenty minutes, and for two minutes on the inside at the expiration of the following twenty-five minutes. The glass in the casements after the first application of water was not displaced. In thirty-five minutes the glass in the north casement fell inwards, and in thirty-six minutes the same happened to the centre one, but that in the south casement remained in position till the end of the test, although damaged at the top.

Another test on the same lines in which the casements were glazed with rolled wired plate glass ¼in. thick. The testee desired forty-five minutes' test; water was to be applied after thirty minutes for one minute on the outside, and again at the expiration of the test. The result was that in twenty-eight minutes the outside of the teak casements took fire. In thirty minutes the glass in the centre casement begun to buckle and let the flames through. In thirty-four, thirty-seven and forty-nine minutes respectively the glass in the three casements began to bend either outwards or inwards, and at the conclusion the glass in the three casements was unbroken, but fused and doubled up into various shapes. This series of tests shows that at least for a time glass may assist as a fire stop.

Skylights glazed with copper electro-glazed squares of prismatic glass, and also wired glass, were also tested, each for thirty minutes; the fire did not pass through the latter.

Fire-Resisting Blinds.

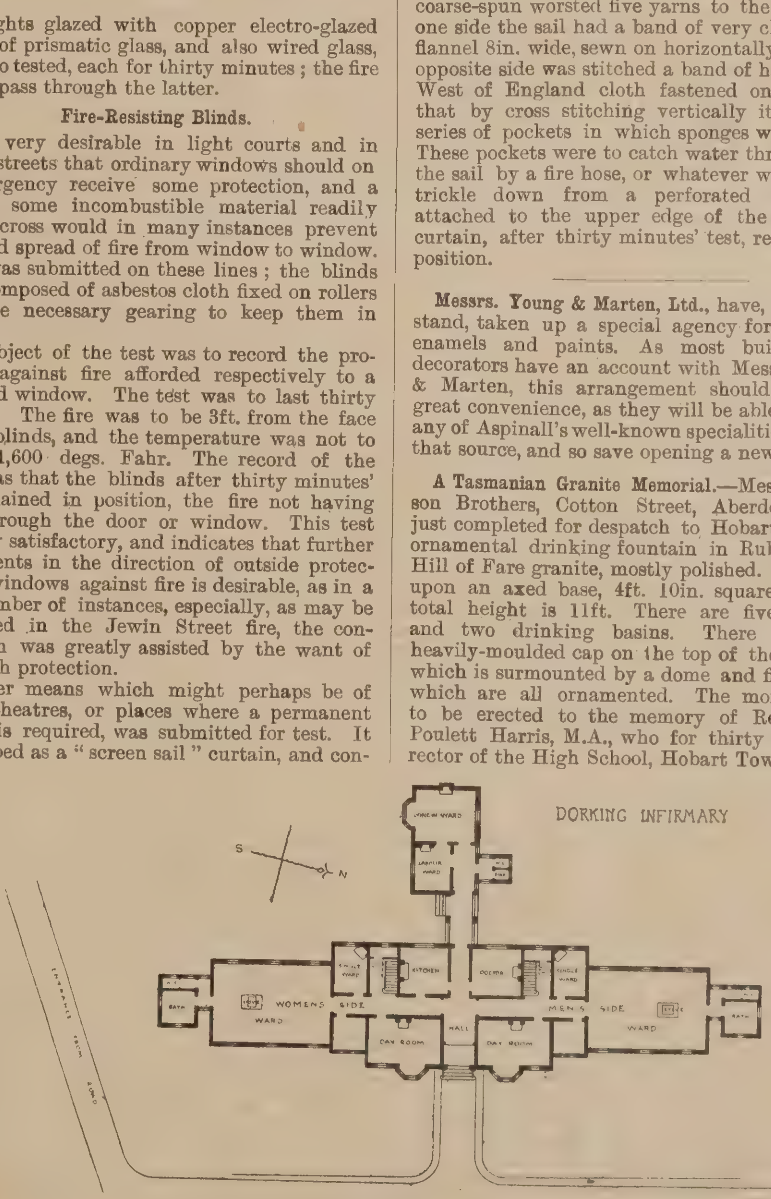
It is very desirable in light courts and in narrow streets that ordinary windows should on an emergency receive some protection, and a blind of some incombustible material readily drawn across would in many instances prevent the rapid spread of fire from window to window. A test was submitted on these lines; the blinds being composed of asbestos cloth fixed on rollers with the necessary gearing to keep them in position.

The object of the test was to record the protection against fire afforded respectively to a door and window. The test was to last thirty minutes. The fire was to be 3ft. from the face of the blinds, and the temperature was not to exceed 1,600 degs. Fahr. The record of the effect was that the blinds after thirty minutes' test remained in position, the fire not having come through the door or window. This test was very satisfactory, and indicates that further experiments in the direction of outside protection to windows against fire is desirable, as in a large number of instances, especially, as may be mentioned in the Jewin Street fire, the conflagration was greatly assisted by the want of some such protection.

Another means which might perhaps be of use in theatres, or places where a permanent curtain is required, was submitted for test. It is described as a "screen sail" curtain, and consisted of woollen material woven of treble-laid coarse-spun worsted five yarns to the inch. On one side the sail had a band of very close-woven flannel 8in. wide, sewn on horizontally. On the opposite side was stitched a band of hard woven West of England cloth fastened on slack, so that by cross stitching vertically it formed a series of pockets in which sponges were placed. These pockets were to catch water thrown on to the sail by a fire hose, or whatever water might trickle down from a perforated hose pipe attached to the upper edge of the sail. The curtain, after thirty minutes' test, remained in position.

Messrs. Young & Marten, Ltd., have, we understand, taken up a special agency for Aspinall's enamels and paints. As most builders and decorators have an account with Messrs. Young & Marten, this arrangement should prove of great convenience, as they will be able to obtain any of Aspinall's well-known specialities through that source, and so save opening a new account.

A Tasmanian Granite Memorial.—Messrs. Simpson Brothers, Cotton Street, Aberdeen, have just completed for despatch to Hobart Town an ornamental drinking fountain in Rubislaw and Hill of Fare granite, mostly polished. It stands upon an axed base, 4ft. 10in. square, and the total height is 11ft. There are five columns and two drinking basins. There is also a heavily-moulded cap on the top of the columns, which is surmounted by a dome and fine finials, which are all ornamented. The monument is to be erected to the memory of Rev. R. D. Poulett Harris, M.A., who for thirty years was rector of the High School, Hobart Town.



CHRIST'S HOSPITAL.

THE GOVERNORS' DEFENCE.

MR. W. VAUGHAN MORGAN, the treasurer of Christ's Hospital, which is threatened with destruction in order that certain funds may be raised, has set up the following defence for the Governors.

When, by a scheme of the Charity Commissioners sanctioned in 1890, the Governors found it imperative that a move should be made, they acquired a site at Horsham, in Sussex, and proceded to erect a new boarding school for boys. The cost involved in this operation, though cut down in every possible way, amounts to no less than £550,000. The building approaches completion, and will be ready to receive the boys in the spring of next year.

"The Governors were advised," says Mr. Vaughan Morgan, "and the Charity Commissioners concurred in the advice, that the realisation of the City site should be postponed as long as possibie, in the belief that a better sale would result. That this site has from the first been been regarded as a source from which the money was to be found to carry out the scheme is common knowledge. The valuable character of the site was, indeed, the main justification for the compulsory removal of the school from London.

"There was and is no alternative for the Governors, forced as they have been to establish new schools elsewhere, but to take the step of realising the site. The time for this has now come, and the answer to objectors who would hinder or stop the sale is that they should have joined with the old Governing Body in resisting the scheme when that scheme was before Parliament eleven years ago; and that it is too late now to talk of preserving the old school buildings unless someone—be it the London County Council or other public body—is prepared to find the money now called for. Of course, if the Governors should be relieved by Parliament from the obligation to provide these latter schools, then the financial requirements would be correspondingly abated; but the Governors being bound by Parliament to provide and maintain these schools, are equally bound to use their best endeavours to realise the site to the best possible advantage.

The Buildings Themselves.

"The Governors are the last persons to deny that historic interest attaches to the site of their institution, and heartily join in the common regret that the removal of the school should involve also the removal of the buildings hitherto used for school purposes. It is a mistake, however, to suppose that the buildings on this site, interesting as they may be, are historical in the ordinary acceptation of that term. The principal of them emanate from no earlier date than that of George IV. The Great Hall, so often confused with the earlier building which the present one displaced in 1825, was built from the plans of the Hospital's architect, the late Mr. John Shaw. And as to the court room, to which the Society for the Protection of Ancient Buildings refers, and which the Governors themselves would naturally much like to preserve if it were possible, it is the room itself which is attractive, as the exterior can hardly be described as beautiful. The building was erected in 1680, and enlarged in 1788.

"The only really ancient piece of building on the site consists of some thirteenth-century arches, rapidly crumbling to decay, which were retained in the reconstruction in 1682 of one of the dormitories over the south cloister. These arches probably formed part—and the only remaining part—of the Grey Friars' Monastery, and will be carefully taken care of with a view to removal to some suitable spot, as will also any other antiquarian and interesting objects which may come to light during the removal. As some of the opponents represent Open Spaces Associations, it may be well to state that the plans of a century ago show that nearly all the ground now used as playground was formerly covered with buildings, and the only portion which has not been built on is the quadrangle and a part of the treasurer's garden.

"The ratepayers, after all, are concerned in the matter; it is they who nowadays have to find the means for technical and secondary education, and the site of Christ's Hospital is an endowment applicable and now dedicated to this purpose. The general public have, therefore, a direct interest in the sale of the site of Christ's Hospital producing the largest sum possible."

THE SOCIETIES' REPLY.

Mr. Lawrence W. Chubb, the secretary to the conference of societies with regard to this matter, makes the following reply to the Governors:—

"The Governors assume it to be proved that it is impossible to carry on the schools of the Hospital in accordance with the scheme of 1890, without sacrificing the whole of the Newgate Street site, and throwing it into the building market without conditions of any kind—indeed, relieved of conditions which would otherwise prevent its being built over.

"This may or may not be true. It has not yet been shown to be so. The Governors are a distinguished and public-spirited body; but it is hardly fair that in a matter of so great importance to London they should be judges in their own cause. They come to Parliament for power to build over their own property. Parliament has before it no materials on which to judge of the necessity of such a step, no accounts, no information as to the expenses, past and future. of carrying on the school, no statement of the possessions and income of the Hospital. The income of the Governors in 1870 was £70,000; they must have a good deal left even after spending what they have at Horsham. Before the destruction of a feature of London of surpassing interest is sanctioned, it seems not unreasonable to ask that a full report from some responsible tribunal, made after a public enquiry, should be in the possession of the Legislature.

The Thirst to Sell.

"The Governors themselves lament the course to which they are impelled, and suggest that some public body should buy the site at its full value. But all the evidence points to a disinclination on their part to utilise the site for public purposes, and a positive thirst for the auction mart or the building syndicate. St. Bartholomew's Hospital is willing to pay more than full building value for the northern part of the site, for they have introduced a Bill for its compulsory purchase; yet the Governors of Christ's Hospital oppose the Bill. It is admitted that two day-schools should be established on the foundation of Christ's Hospital within three miles of the Royal Exchange. What more central site than Newgate Street could be suggested? Yet the Governors will not entertain the idea of adapting any of the existing buildings for such a purpose. Again, the Governors must have offices, a court-room for their weekly meetings, and possibly a hall for the entrance examinations of their boys and girls. But they do not seem to have thought of the possibility of retaining their present court-room, and would actually, it seems, hire or buy other premises for these necessary purposes. If time were allowed, other public uses might not improbably be found for the whole or portions of the site. But the Bill of the Governors alludes to actual negotiations, and there seems to be no question that, if passed in its present form, the property will be sold as an unoccupied site at a price per foot, and be devoted wholly to commercial purposes.

Apropos the Architecture.

"Although lamenting the destruction of their buildings, the Governors rather ungraciously attempt to belittle their interest. No one has suggested that the Great Hall is ancient; but it is a very fine hall nevertheless, as any one may judge who will obtain admission to the organ gallery and watch the boys at their midday meal. It may no doubt be true that little of the existing buildings has survived from pre-Reformation times; but the Governors themselves refer to the reconstruction of 1682, and tell us that their court-room was built two years earlier. Wren was then in his prime, and many persons will be of opinion that his buildings and those of his school can be as badly spared as the buildings of any earlier epoch. A few steps up Christ Church passage will disclose a beautiful facade of Wren's work, disfigured only by the vandalism of the Governors, who have recently torn away the end of the building and the effigy of King Edward.

"The Governors think it is an answer to the statement that a large area of open space will be lost to London to say that most of the playground was formerly covered with buildings. Whether this is so or not seems of very little importance. Long before London took its great growth—for it was a comparatively small place even fifty years ago—the present playground and garden existed. They have kept the heart of the City sweet, and if they cease to exist the whole of London will be the poorer. Moreover, it is admitted that the area known as the Ditch, the old 'Garden' of the Grey Friars, which has maintained its name to the present day, and the Treasurer's Garden are open spaces of immemorial age. The preservation of this area alone would be of inestimable value.

Governors cannot Blow Hot and Cold.

"Finally, it is sought to explain away the very fact which has necessitated the present application to Parliament. But the Governors cannot blow hot and cold. Their Bill seeks to give them authority to sell the site freed and discharged from any restrictions (statutory or otherwise) which may affect the same by reason of any part or parts thereof having been used or set apart for purposes of interment, or consecrated. If no part of the ground came within the Acts which forbid building on disused burial-grounds, the proposal of the Bill would have no meaning. The mere removal of human remains can be accomplished under the authority of the Home Secretary, and is no sufficient ground for the Bill.

"This is not a question which should be decided hastily and on *ex parte* statements. Great profits are a tempting bait, even for a charitable foundation. It should be ascertained beyond doubt that it is not the mere wish to handle large sums of money which impels the Governors to the course they now propose.

"London will lose irreparably if Christ's Hospital as it now exists is replaced by shops and warehouses. The foundation is a very wealthy one, and it should be called upon to show how it makes out the necessity for such a disaster."

At last week's meeting of the London County Council it was decided to oppose the Bill (see p. 269 of this issue).

ST. GEORGE'S CHURCH, LEEDS.

AFTER being closed for many months, during which period it has undergone extensive restoration, the church of St. George's, Leeds, has just been reopened. The whole of the old "box" pews on the ground floor have made way for seats of polished pitch-pine, while the electric light has been substituted for gas. The old flat plaster ceiling has been removed, and an open-timbered roof of stained pitch-pine substituted. Another important work has been the breaking through of the east wall, the insertion of a lofty chancel-arch of stone and the erection of an apse with wall arcading and five lofty traceried windows, a new clergy vestry being built on the south side of the apse. The entire area of the church has been covered with a layer of concrete 6in. thick, and a new wood-block flooring has been laid down. The chancel has been enriched by elaborate oak choir-stalls, oak clergy-stalls with carved and traceried canopies, and an octagonal pulpit of oak, with canopied niches containing figures of the Evangelists at the corners. A fine old painting by Cope occupies a position on the wall of the new apse. There is a new holy table of carved oak. The space under the tower now forms the baptistery. A new oak screen, forming a lobby, with traceried panels and folding doors, has been added. A new gallery front in open pitch-pine has been erected, and a new heating apparatus introduced. The organ, thoroughly overhauled and added to, has been refixed entirely on the gallery floor. The estimated cost of the restoration is £7,500. The structural alterations, including the apse and the roof, are from the designs of Mr. Henry Walker, architect, of Leeds; the interior screen work, stalls, pulpit, gallery front, &c., are from designs by Mr. G. H. Elliot, of Lightcliffe, under whose supervision the whole of the work has been carried out.

THE CASTELLO AT MILAN.

A WONDERFUL BUILDING.

MILAN is just now full of travellers passing to or from Rome and the Riviera, and a fair proportion of these are careful to see the leading sights of the city.

"But," says a correspondent of the "Times," "there is one sight which has not yet got into the guide-books, and which yet is so interesting that it ought not to be missed by anyone who cares for art and history, or by anyone who can take pleasure in one of the most ingenious and legitimate pieces of 'restoration' that the world can show.

"This is the famous Castello Sforzesco, the fortress-palace which the Sforzas built on the ruins of the older Visconti building, and which, after undergoing many sieges, many partial attempts at destruction, and the neglect of centuries, is now in a fair way to recover, almost completely, the form and outward beauty of its prime. One of the inner courts is finished, and here have been arranged all the treasures of the old Museo Civico and many others; the other court, the frowning Rocchetta, is rapidly nearing completion; and the more extensive rebuilding required by the forecourt is proceeding, and will probably be finished in three years.

"The whole may be said to be the work of one man, Signor Luca Beltrami, the architect, a man still young, but one who has already devoted fifteen years of his life, first to persuading the people and the Municipal Council of Milan that the restoration of the ruin was feasible, and then to carrying it out, with an ability and a success that are little short of marvellous.

"The largest, finest and historically most celebrated of the castles built by the despots of the Renaissance has been recovered, and a multitude of relics of the past of Milan and of Lombardy have been stored within it.

Signor Beltrami's Principle.

"The principle followed by Signor Beltrami, to whom the chief direction of the work was confided, appears to have been this: Where restoration was a matter of absolute certainty there should be restoration, but in all other cases things should be left as much as possible in the state in which they were found.

The Frescoes.

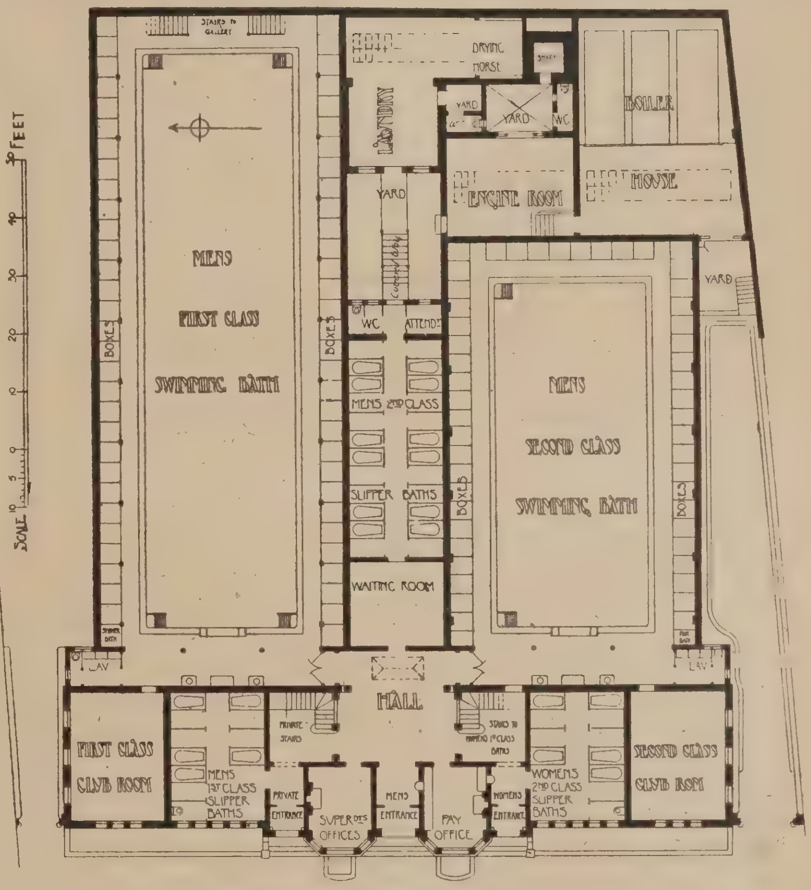
"It is scarcely necessary to say that of the fresco painting which was the glory of the Castello in the time of Ludovico il Moro very little remains, and that no attempt has been made to 'restore' here. The two most interesting frescoed chambers are the chapel and a little room which the enthusiastic *custode*, following a somewhat dithyrambic German writer who ought to have known better, calls the study of Lionardo da Vinci. . . . . The decorations of the chapel, though mere shadows and fragments of what they once were, are of extreme interest. A series of indications—little more—of single figures of Saints, a few feet apart, have been discovered all round the building—the work, as documents prove, of the painter Montorfano and other Lombard artists who worked before the advent of Lionardo. The originality of the decoration consists in the square tile-like pattern, worked in stucco in very low relief, which forms a background for the figures. It is the sort of work which would have delighted the soul of Burne-Jones, who would have realised the extraordinarily rich effect which might have been obtained from it.

Sculpture.

"The rooms that are already finished, in and about the Corte Ducale, already form a museum of no small importance. The first room contains a number of Roman and pre-Roman remains, not without importance to the archæologist; in the central loggia is the fine fourteenth-century monument of Barnabo Visconti (A.D. 1380); and fixed in a neighbouring wall is the magnificent doorway which was sculptured by Michelozzo for the Medici bank in Milan. This fine work dates from nearly a hundred years later, and is therefore an example of the best period of Renaissance design; it was acquired not long ago by public subscription, to save it from the danger of destruction. In the rooms to the right are a large number of examples, most of them mere fragments, but some comparatively complete, of sculpture from 1400 to 1550 . . . . The chief artists represented in these rooms are Amadeo, who did such splendid work at Certosa and at Bergamo, and the sculptor called Bambaja, the fragments of whose unfinished masterpiece, the tomb of Gaston de Foix, are now here, after undergoing many and deplorable vicissitudes . . . . An adjoining room contains a number of examples, fragmentary but still interesting and likely to be of practical use to the Lombard builders and architects of the future, of the beautiful terra-cotta ornaments which are such a characteristic feature of Lombard architecture."

PLAISTOW PUBLIC BATHS.

ON Thursday last the new public baths at Plaistow, E., erected from the designs of Mr. A. Saxon Snell, F.R.I.B.A., were opened by Councillor Abednego Bishop, J.P., Mayor of West Ham. We give on this page a plan of the baths, and, as centre plates, illustrations of the exterior and interior.



PLAN OF NEW PUBLIC BATHS AT PLAISTOW, LONDON, E.
A. SAXON SNELL, F.R.I.B.A., ARCHITECT.

In so extensive an area as that embraced by the Borough of West Ham, it was obviously impossible to provide one set of baths, however large, which could be conveniently placed for the needs of the whole borough. It was therefore thought desirable to build a separate set in each of the two great divisions of the borough—Plaistow and Stratford. The present buildings are therefore only part of the general scheme. They are built upon the site of the garden of No. 40, Balaam Street, one of the oldest houses in the district.

Before committing the borough to any scheme, a committee of the council visited and inspected a number of the latest and best types of public baths in the Metropolis, including the large baths and wash-houses at that time just completed for St. Marylebone Parish by Mr. A. Saxon Snell. A contract was entered into with Messrs. Spencer, Santo & Co., Ltd., of Westminster, for the erection of the building at a cost of £22,308, and in May, 1889, the foundation-stone was laid.

The establishment comprises first- and second-class swimming baths, twenty-seven warm baths, and the usual towel laundry and boiler-house, &c. The main entrance is in the centre of the Balaam Street frontage, and leads to a large waiting hall, itself giving access to the various departments. This entrance will be used by both first- and second-class male bathers, and, as well as the hall, is overlooked by the superintendent's office on one side and the pay-office on the other. On the south side of the pay-office is another separate entrance for women, from which access is obtained to the first- and second-class warm baths and to the second-class swimming bath, when it is desired to use it for women. On the north side of the superintendent's office is the private and committee-room entrance. On either side of the main hall are respectively the first- and second-class swimming baths, and between the two, and approached by a special waiting room, are twelve second-class warm baths for men. The first-class men's baths (five) are on the ground floor in front of the first-class swimming bath. The second-class women's baths (five) are in a similar position with respect to the second-class swimming bath, the first-class women's warm baths being immediately above and approached by a specia staircase. The staircase on the north side leads to the board-room and private apartments. The first-class swimming bath is 100ft. long by 27ft. wide, with a depth ranging from 3ft. 6in. to 6ft. 6in. On two sides are arranged sixty-one dressing boxes. Lavatory basins and a special shower bath are also provided. A wide gallery runs round all sides, and is approached from the staircases at the end of the bath hall as well as from the main staircase. A large club room is attached, fitted with lockers and other conveniences. The hall walls are lined up to the gallery level with white-glazed tiles, and above the gallery with white-glazed bricks, relieved with coloured bands. It is lighted by an extensive lantern and skylights. There are two diving-boards. The bath itself is lined throughout with white-glazed tiles and relieved with coloured bands and ornamental tiles. The footways are laid with vitreous mosaic, with a slate border all round. The second-class bath is 60ft. by 27ft., with a depth ranging from 6ft. to 3ft. Round three sides are ranged fifty-one dressing boxes, and a special foot bath, and lavatories are also provided. A short but wide gallery is placed at the west end only. The hall walls are faced with white-glazed bricks to the height of the dressing boxes. The bath sides are lined with white-glazed tiles, and the bottom with white- and blue-glazed bricks. The footways are paved as described for the first-class bath. The warm baths generally are placed in cubicles formed with enamelled slate divisions and doors, and fitted with porcelain enamelled baths, and special hot- and cold-water fittings, controllable only by the bath attendant. Hot and cold showers are also provided. In the first-class bath-room the floors are laid with vitreous mosaic, and the second-class with patent paving. In the rear of the second-class bath are the towel laundry (fitted with power-driven machinery and steam-heated drying horses), an engine-room in which is placed a small Tangyes' engine, and a boiler-house fitted with two Galloway double-flued boilers. A large coal store has been constructed under one of the footways of the second-class bath. The engineering works have been executed by Messrs. Rosser & Russell, of Charing Cross. The late Mr. James Brooks acted as Clerk of Works for the foundation, and Mr. W. C. Gardner for the superstructure.

R. I. B. A.

ANNUAL GENERAL MEETING.

THE annual general meeting of the Royal Institute of British Architects was held on Monday evening last.

The annual report referred to a number of matters which have already been reported in these columns, such as the King's continuance of the grant of an annual gold medal, the results of examinations, awards of prizes and studentships, the General Architectural Congress held last June, &c.; so that there is now no need for us to recapitulate.

The Institute at present has 1,696 members on its roll, an increase of eighteen over 1900.

During the past year twenty-nine Fellows have been elected, forty-six Associates, three Honorary Associates and one Honorary Fellow. Two Honorary Corresponding Members have been elected, J. Antoine Bouvard (Paris) and J. G. Pedro d'Avila (Lisbon).

The Council attribute the smallness of the increase in membership in the class of Fellows to the more than usually heavy losses by death, by resignation, by transference to the class of Retired Fellows, and by other removals from the list. There have been only three special elections to the Fellowship by the Council under the new proviso to by-law 9, as compared with eleven last year and twelve the year before. On the other hand, the ordinary elections to the Fellowships by the general body have been twenty-seven, as against twenty-one, fourteen, and eight respectively in the three preceding years.

The losses by death have been as follows: Fellows: Charles Barry, H. C. Boyes, J. Burnet, J. Butler, F. Chambers, Henry Currey, C. H. Driver, W. C. Evans-Vaughan, Joseph Goddard, Horace Gundry, E. J. Hansom, T. Harris, W. Hepper, N. E. Jennings, T. M. Lockwood, W. H. Powell, J. M. Robertson, Lloyd Taylor, J. Buckley Wilson, W. Young. Associates: J. W. Blakey, F. Borham, H. G. Wade. Retired Fellows: H. A. Darbishire, W. M. Teulon, J. J. Thompson. Honorary Corresponding Members: Giuseppe Poggi, Antoine Henri Revoil, Jules Jacques van Ysendyck.

The total number of candidates examined during the year was 600, as against 548 in 1900. The number of Probationers of the Institute now stands at 1,507, and Students at 368.

The "special" examination will be held this June in Sydney and Montreal.

The Fifth International Congress of Architects was held at Paris during the week commencing July 30th. The Institute was represented by Professor G. Baldwin Brown and the secretary. The Sixth Congress will be held in Madrid in the spring 1903.

The Council were invited by the Glasgow International Exhibition of 1901 to contribute to the Fine Art Section an exhibit from the collections of the Royal Institute, a bay in one of the galleries being placed at their disposal. The Council have complied with the request, and have sent the portraits of Professor Cockerell, Sir Gilbert Scott and Mr. F. C. Penrose; marble busts of Inigo Jones, Sir Christopher Wren, Sir Charles Barry and George Edmund Street; and a large number of drawings.

The Council have acceded to the request of the Glasgow Institute that the R.I.B.A. annual dinner shall be held this year in Glasgow. It will take place on Thursday, October 3rd. An interesting programme has been drawn up for the visit, and the Corporation of Glasgow have kindly arranged to entertain the Royal Institute at a reception on Friday evening, October 4th. The Council most earnestly hope that as many members as possible will attend, so as to ensure the success of the gathering.

The Holborn-to-Strand Scheme: What the Council Did.

The Council were asked by the London County Council to co-operate in the Holborn-to-Strand Improvement Scheme, and a deputation waited on the Improvement Committee to protest against the proposed conditions. They suggested that there should be a competition among the eight architects, and that three should be chosen to carry out specified blocks, working together, however, as a consultatory committee on the whole scheme. The interview resulted in a few modifications in the conditions as to the details of drawings required and an increase in the honorarium offered to £250. The Council were given to understand that there could be no guarantee that any of the eight architects should execute all or part of his design, and the invitation to co-operate was renewed on the slightly modified basis. Desirous of aiding the London County Council in their efforts to secure architectural treatment for the new street, the Council accepted the invitation under strong protest, and nominated four architects. Their names were Messrs. Reginald Blomfield, T. E. Collcutt, Ernest George and R. Norman Shaw. Two of them, Messrs. Collcutt and Shaw, declined the nomination. The Council were requested to nominate two others in their place. In view of the London County Council's disregard of their protest accompanying the original nomination, the Council considered that they had gone as far as was consonant with the dignity of the Institute, and the profession which it represents, to meet the wishes of the London County Council, and formally declined to make further nominations.

The London County Council also submitted for the opinion of the Council their draft by-laws under the Metropolitan Management Acts, as to the disposal of plans with reference to pipes, drains and other means of connecting with sewers. The main suggestion of the Council was that in lieu of elaborate duplicate plans and sections, which it was proposed that any one about to construct or reconstruct drains, &c., should deposit with the sanitary authority, it would be sufficient if one carefully-prepared block plan were sent.

The Council have also adopted the report of the Science Committee with regard to a scheme suggested by the Plumbers' Company for the hall-marking of plumbers' work, and they have arranged with the Plumbers' Company for a conference to be held between the company, the Royal Institute, and the Water authorities with a view to settle the best kinds of materials and forms of fittings used in plumbers' work, and to provide a basis for regulations on the subject.

The Council regret that their negotiations with the Institute of Builders, extending over a space of two years, have come to a fruitless conclusion.

The Joint Committee of the Institute and the Surveyors' Institution respecting ancient lights have been authorised to draft a public Bill on the lines of their report, and to submit it for consideration to the two Councils; the Bill is now in the hands of a Parliamentary draughtsman.

The Council have reappointed Mr. Thomas W. Cutler as the representative of the Institute on the Sanitary Inspectors' Examination Board. At the Congress of the Royal Institute of Public Health, to be held at Eastbourne in July, Mr. Herbert Spurrell has consented to represent the Institute. Messrs. Alexander Graham and Edwin T. Hall will represent the Institute at the British Congress on Tuberculosis to be held in London this year, also in July.

The Council recommend to the attention of members the Architectural Museum, Tufton Street, Westminster, which is somewhat in need of funds for purposes of repairs, maintenance of the 4,000 casts of examples of Gothic work, and the purchase, if possible, of casts of Classic and Renaissance examples. They feel that the support of the profession at large is deserved by a most valuable institution, whose foundation and maintenance have been the devoted work of a few men. The Council have decided to make the museum an annual grant of twenty guineas, provided they are adequately represented on the committee of the museum.

The question of architects' names appearing on advertisement boards has come before the Council, and they have issued a resolution to the effect that the signing of an architect's name on his building is not derogatory to the profession, but that "it is undesirable for architects to place their names on boards and hoardings in front of buildings during course of construction for purposes of self-advertisement." The Council earnestly hope that members will co-operate with them in making this resolution as effective as possible.

The Council take this opportunity of drawing attention to the needs of the Architects' Benevolent Society, and express the hope that the names of more members of the Institute will appear in the list of subscribers.

The balance-sheet of the Institute shows the sum of £843 19s. 3d. on the right side. The estimate for the year ending December 31st next shows a balance of income over expenditure of £1,100.

In their report the Literature Standing Committee announce that since the date of the last report eleven original drawings, attributed to Inigo Jones, have been discovered by the librarian in the collection of the late Anthony Salvin. These have been carefully mounted under the direction of Mr. R. Phené Spiers.

The Practice Standing Committee say in their report that, as anticipated, the revision of the Institute pamphlet on "Dilapidations" has been found to necessitate the creation of virtually a new book. This has been divided into chapters, each under a definite heading. Several of these chapters are completed, and the remainder are in hand. The Committee hope to send the new book in proof to the Council before the end of this session.

The Science Standing Committee report that the results of the experiments for the purpose of ascertaining the strength of different kinds of brickwork will, it is hoped, be issued shortly in pamphlet form. At the request of the University of California, Berkeley, U.S.A., whose College of Chemistry has arranged a special course on the chemistry of structural materials, specimens of stone, brick, and mortar of known age, ancient as well as modern, were collected and forwarded to the College, and the results of the analyses will be duly communicated to the Institute. The supporting power of rocks and soils is still under enquiry. The Committee are collecting particulars from various sources.

After the annual report had been adopted, Messrs. Hippolyte J. Blanc (Edinburgh), C. Fitzroy Doll (London), and E. H. Sedding (Plymouth) were elected Fellows, and Mr. R. Douglas Wells (London) was elected Associate.

A New French Bridge.—The French Minister of Public Works has approved the designs for a steel railway bridge, which will be the highest in the world. It will span the valley of Sioule, on the line in construction from Saint-Eloy to Pauniat, in the Allier, Central France. The trestle construction is adopted, the total length being a little over 400yd., divided into three spans by two piers of masonry 300ft. high. The height of the rails above the centre of the valley is 435ft. The bridge will cost £112,000.

Protection of the National Gallery against Fire.—Sir Edward J. Poynter, in his report, calls attention to the lessening of the danger to the National Gallery by fire. The water pressure on the roof has been increased. Steps have been taken for the purchase of contiguous business premises, and it is hoped that the isolation of the gallery may be effected in a reasonable time.

BRICKMAKING IN HUNGARY.

CONSIDERABLE attention has, during the past few years, been drawn to Hungary by the internal dissensions in the Austrian Parliament at Vienna and the constant differences arising between the two foremost provinces (Austria proper and the kingdom of Hungary) which combine to form the backbone of the monarchy. Thus, politically, Hungary has become exceptionally well known to the world in general. In an industrial sense, however, it may with assurance be claimed that the knowledge of the public concerning the affairs of this growing young country, lying on the boundaries of the outposts of Orientalism, is limited.

Vienna and Budapest.

Hungary's continuous opposition to the rule of Austria, as laid down by the Viennese Parliament, has to one possessing a knowledge of the nation's resources and strength, the semblance of a young giant's protest against the arbitrary sway of a weakling. For in strength and power Austria proper is rapidly growing to look puny in comparison with the budding forces of Hungary. While Vienna fails to advance either in the size of its population or in the importance of its industries, Budapest is springing ahead with leaps and bounds. The latter city is called the "Chicago of Europe," because it is said to have come up in a day. Vienna introduced a system of electric traction two years ago; Budapest did this six or eight years ago. The streets of Vienna are still poorly lighted by gas; Budapest is nightly illuminated by as fine a system of electric lighting as can be found anywhere in Europe.

To continue the comparison to another important feature, namely, building, Vienna builds slowly and laboriously, whereas in Budapest fine structures rise with the rapidity of skyscrapers in the United States. In Vienna, when a building projects so far into a street as to interfere with traffic or with street improvements, it is torn down and rebuilt. Budapest hires a building-mover from Chicago and moves palaces, stores, residences and anything else that may be required.

These are only a few instances of the push and energy evinced by the Hungarians in their municipal affairs. Similar conditions apply to all branches of their industries and commerce in general. Austria taxes her industries to the fullest extent possible, while Hungary stands ready and willing at all times to facilitate the establishment of manufactories by the granting of special inducements, such as exemption from taxation, low gas and water rates, and the score of other privileges which it is in the power of Governments to grant for special purposes.

This condition of progress renders the brick industry of Hungary of peculiar interest at present, especially as the various cities of the kingdom give evidence of a yearly increase in the demand for building materials reaching well into the millions.

The Main Centre

of the brick industry of Hungary is situated in the district immediately adjacent to Budapest. In this locality are the principal plants, amounting altogether to the considerable number of twenty-seven. As far back as 1897 the total annual production of these plants was 400,000,000 bricks, which amount increased in 1898 to 500,000,000. In 1899, however, a reaction set in, and, through the depression of prices following a slight over-production, the total output dropped to two-thirds of the figures representing 1898, or a little over 300,000,000. Accompanying this loss in output came a drop in the prices to 21s. 6d. per 1,000, at which price it was difficult for the makers to realise the cost of production, without thought of profit. As a result, outputs were on every hand reduced, working forces were cut down and those kept by the plants were paid 16s. 6d. to 30s. a week—wages considered high in Hungary, but necessitated by the strike of the previous year.

Outputs.

The effect of the depression is perhaps best llustrated by the following outputs of various irms in 1899 as compared with the preceding year. In 1899 the Draschesche Kohlen-Bergbau and Ziegelei-Actien-Gesellschaft, one of the largest companies in Hungary, which produced in 1898, 82,000,000 bricks, was able to turn out in 1899 only 54,000,000, while the output of the Kobanyaer Dampfziegelei-Gesellschaft dropped during the same period from 50 to 25 million bricks, and the Ujaker Ziegel und Kalkbrennerei Actien-Gesellschaft turned out only 27,000,000 bricks, as against 35,000,000 in the previous year.

The production of the Dampfziegel-, Cement- und Gypsfabriken-Actien-Gesellschaft is also interesting. This company manufactured in the year 1898 37½ million bricks and 1,750 carloads of cement, as compared with 37,000,000 bricks in 1897, 27,500,000 in 1896, and 20,000,000 bricks and 1,200 carloads of cement in 1899. The condition of the provincial industry was also unfavourable in 1899. Not only was the total output considerably reduced, but the low price of 21s. 6d. prevailing in Budapest effectually closed the capital city as an outlet for inland-made bricks, and thus added the proverbial last straw to the Hungarian brickmaker's back.

A Much-needed Tonic.

According to reports which have emanated from Hungary during the past year, however, the increased demand for bricks during the current year has proved a much-needed tonic to the industry. The plants have been able to employ more labourers, and a considerable improvement in the prices has taken place. One of the leading companies in the kingdom, which had erected a new plant in 1898, for operation in 1899, has been able to turn out a very fair quantity, much against the general expectation of the trade. Wages also have improved, day labourers earning from 1·20 to 1·50 florins (2s. to 2s. 6d.) per diem, and piece-work men getting from 25s. to 36s. per week. That such good results were attained is due almost entirely to the circumstance that the building activity in Budapest, instead of abating, has not only steadily progressed, but offers bright prospects for the future.

Leading Plants.

The leading plant in Hungary at present engaged in the manufacture of bricks is the Draschesche Steinkhlen-und Ziegelfabrik Gesellschaft, in Budapest, which is equipped with facilities capable of turning out from 91 to 100 million bricks. Next in importance to this are probably the Kobanyaer Dampfziegelei, a concern fitted for an output of 50,000 bricks; the Ungarische Dampfziegel-, Cement & Gypsfabrik Actien-Gesellschaft (equipped for producing, if necessary, 45 million), the Ujaker Ziekel- & Kalkbrennerei (40 million), the Vereinigten Zingel & Cement Fabrik-Act. Gesellschaft, all of Budapest; the Kalocsaer Dampfziegelei Actien-Gesellschaft, in Kalocsa; the Erste Exporte Dampfziegel Deckziegel- & Keramische Fabrik-Actiengesellschaft, in Kecskemet; the Budapest Tegla es Meszege-togyar, the Lechner Rakosi Teglagyar Reszvenytarsasag, the Victoria Teglagyar, the Apatini Teglagyarak and the "Itvan" Teglagyar Reszvenytarsasag, all in Budapest. Besides these there are, of course, a score of minor-class works, whose titles are so difficult to read or pronounce that it is inadvisable to embody them in this article.

German Machinery.

The bulk of the plants that boast up-to-date equipments are operated by German machinery. There are some ten or twelve German manufacturers of brick machinery in the Hungarian market, all of whom have reaped good profits from their Hungarian trade. An idea of the exact value of Austria-Hungary as a market for foreign brick machinery may be gathered from the following statistics for 1899, recently published at Vienna. According to these the imports of brick machinery, which in 1897 amounted to 483,750 guldens (£38,700), rose in value in 1898 to 560,340 guldens (£44,829), and in 1899 to 822,330 guldens (£65,788). In 1899 Germany's share of these imports amounted to 804,240 guldens (£64,339), that of Great Britain to 4,680 guldens (£454), of Italy 450 guldens (£36), while the United States supplied in all 9,180 guldens (£734).

Owing to the fact that the statistics of Austria and Hungary are classed together, it is impossible to distinguish between them, but that Hungary's share is large is evident from the enormous growth that has taken place in the industry in recent years.

During the year 1899 stone-working machinery was imported to the amount of 21,230 florins, of which 14,300 florins worth was of German origin, 5,940 florins worth of Belgian origin, while the rest came from Switzerland and Great Britain.—From the "Clayworker" (Indianapolis, U.S.A.).

EXCAVATIONS AT NIPPUR.

INTERESTING DISCOVERIES.

IN 1888 the University of Pennsylvania despatched an expedition to excavate Nippur, an ancient city of Babylonia, situated midway between the Tigris and Euphrates, about fifty miles to the south-east of Babylon. All that remains of the city is an extensive group of mounds, which rise on an average to about 60ft. above the plain.

For eleven years, including interruptions, the "death-like stillness" which brooded over this ancient city (the probable site of Calneh, Genesis x. 10), with its treasures of long-forgotten millenniums, has been dispelled, and the place has been the scene of much activity on the part of the American expedition. Though much has been accomplished in the laying bare of ancient buildings, yet at the present rate of operations, although on an average several hundred Arabs have been employed, it will require fully 100 years to excavate thoroughly this ancient city.

A Large Palace Discovered.

Concerning the results of the work Professor Hilprecht, the scientific director of the work, has been able to report that the most sanguine expectations have been realised. In tracing the southern limits of the city a large palace of the pre-Semitic period (before 4000 B.C.) was discovered. No mound marked its site. It was clearly below the present level of the plain. Only one facade of the building was cleared. It is nearly 600ft. long, built with two storeys, having small windows near the ceilings. A large open terra-cotta vase, several tablets of the earliest known period, a substantially-constructed well, and many other antiquities, were discovered. The fact revealed in connection with these and other investigations is that the city in the earliest known period had the same enormous extent as in the late Neo-Babylonian period, and the territory embraced within the walls was at that time more fully occupied.

The Temple of Bel.

One of the highest points of Nippur is the conical mound called Bint-el-Amir ("Daughter of the Prince") by the Arabs who live in the neighbourhood. It rises about 95ft. above the plain, and covers the ruins of the ziggurrat Imkharsag, the stage tower of the temple Ekur. About the tower on all sides are the buried rooms and collapsed walls of the temple proper. Considerable time in the past has been devoted to the excavation of this structure. The uppermost stratum of the mound, not unlike nearly all the others examined, was found to be a cemetery, where in the period from about 200 A.D. the residents of Nippur buried their dead over the place where their ancestors worshipped their gods. Beneath this stratum were found the operations of those who built during the Parthian period, when a complete change in the form and character of the structure was made. Beneath this structure was found the temple that had been built by Ashurbanapal (668-626 B.C.). This Assyrian monarch restored and greatly enlarged the temple which had existed previous to his time. The next great builder, going backwards in the order of time, was Kadashman Turgu (1250 B.C.). The work of Kurigalzu, Bur-Sin II., Ishme-Dagan, Bur-Sin I., Ur-Ninib, and Dungi, of the third pre-Christain millennium, was also cleared away after being examined in all details when the ziggurrat, as it was seen in the time of Ur-Gur (2800 B.C.), was laid bare. Professor Hilprecht does not hesitate to date the founding of the Temple of Bel and the first settlements in Nippur somewhere between 6000 and 7000 B.C., possibly even earlier. Belonging to the temple at different periods previously to Sargon's time were found in this early stratum an altar covered with ashes of animal sacrifice; several large sacrificial vases made of terra-cotta; a perfect keystone arch, hitherto considered Roman, and many other interesting works of antiquity in bronze, stone and clay.

A Library of Clay Tablets.

The temple library has been found, and altogether there have been taken thus far from its rooms about 25,000 tablets, mostly unbaked. As only about one-twentieth part of this extensive group of hills has been excavated, in view of the peculiar topographical indications and the history of the temple, Professor Hilprecht estimates the probable number of tablets yet buried in the library to be from one hundred to one hundred and fifty thousand. They are almost entirely of a didactic character, and belong to the third millennium before Christ. The Elamites threw the building into ruins the century prior to Abraham's birth.

Smaller Art Relics.

Important inscriptions on clay and stone belonging to all periods of Babylonian history were also found during the last campaign in great numbers. In removing the upper stratum of mounds over one thousand sarcophagi, mostly of the slipper-shaped pattern characteristic of the late period (300 B.C. to 700 A.D.) were opened. In these were found gold and silver jewellery in the shape of bracelets, finger rings, nose rings, brooches, clasps; also pottery and many other things. Seal and seal cylinders, such as the Babylonians used in their business transactions; several hundred inscribed Hebrew and Mandaic bowls, showing the influence of Babylonian wizardry upon the Jews who continued to live at Nippur as late as 700 A.D.; great numbers of vases in enamelled and plain pottery, images of gods, playthings in terra-cotta, bas-reliefs, weights, utensils and coins in bronze and iron, &c., were found. Another important feature was the studying of all types and forms of pottery with a view to determining the age of many specimens excavated in former years. As regards portable antiquities of every description having special archæological value for the restoration of Babylonian history, this expedition stands prominently in the lead of those at the present time engaged in Babylonia.

A NEW CHAPEL AT OSMASTON.

A NEW chapel is being erected for the Wesleyans at Osmaston-by-Derby. The new church will occupy a position on the east side of the main road. The site runs through to Taylor Street, having two frontages. The present iron building facing Taylor Street will remain, pending the erection in the near future of the school block. The present contract includes the church, two vestries, and cloak-rooms. The style of architecture is Gothic. The church will be 59ft. long and 37ft. 6in. wide inside and 46ft. 4in. across the transepts, with an orchestra 15ft. by 13ft. There will be a gallery at one end only. The seating capacity will be for 433 adults, or a mixed congregation of 560 persons. The walls will be of brick with Derbyshire stone dressings. The front will have a double doorway with richly moulded jambs, and shaft of polished granite, with foliated caps, and over these will be a four-light window. These will be flanked with buttresses, having pinnacles and foliated finials. The roof will be partially open, with pitch-pine ceiling, and the timbers visible with arches underneath, and moulded wood tie beam and king post. The outline of ceiling is one that the architect has adopted because of its acoustic results. The joinery throughout will be of pitch-pine. The seats have solid ends. The rostrum will be of pitch-pine with panelled front, and open ends with wrought-iron balusters. The contract is let to Mr. W. Edwards, of Derby. The outlay, including the cost of land and architects' fees, will be about £3,000. The architect is Mr. John Wills, F.S.Sc., of Derby and London.

A New Water Reservoir is being constructed on the Appscourt, or Abb's Court, estate at Walton, by the Southwark and Vauxhall Water Company, to hold no less than 1,076 million gallons of water.

Masters and Men.

The Stockton Painters' Dispute has been amicably settled, the men having accepted an advance of a ½d. per hour in place of the 1d. and no overtime they asked for.

The Darlington Bricklayers, who struck recently for 10d. per hour instead of 9d., have accepted the masters' proposition that if the men's demand were withdrawn they would guarantee that no reduction from 9d. should take place for two years. The men, however, added a proviso to their acceptance that all of them applying for work be again reinstated, and, further, that all those who had commenced work in their places be discharged.

The Leicester Bricklayers and Labourers employed on the new wholesale market, who struck recently, have resumed work on condition that their alleged grievance will be fully discussed and settled by a mutually representative committee. Particulars of their demand were given on p. 246 of our issue for last week.

A Strike in the Hartlepools has occurred of 110 bricklayers' and plasterers' labourers, who have met a proposal of the masters to reduce their wages by a penny an hour by a demand for a halfpenny an hour increase. These represent only about half of the labourers employed in the district, several of the employers. builders, contractors and sub-contractors having agreed that the present conditions of labour and rate of wages shall continue. The present wages of bricklayers' labourers in the Hartlepools are 7d. and of the plasterers' labourers 7½d. per hour. The bricklayers are also asking for an advance of a halfpenny an hour on their present wage of 9½d., and the joiners ask for a penny per hour advance.

Dispute in the Bradford Building Trade.—The Bradford Federation of Master Builders have locked out all the carpenters and joiners, masons and bricklayers, and bricklayers' labourers who are members of the Operatives' Societies. This step is due to the non-acceptance by the men of arbitrations upon the several points in dispute, which are as follows: the joiners ask for a penny an hour advance from 8d to 9d., and refuse the masters' offer of 8½d.; the masons object to a penny an hour reduction from 9d. to 8d.; the labourers ask for a ½d. an hour advance, previously having asked for a penny advance; and the bricklayers are thrown out in consequence. The masters also desire to submit to arbitration a suggested alteration of the rules so that unionists and non-unionists should be allowed to work together, and that notices for alterations in rules should come into force half-yearly, on the 1st of November and the 1st of May, and not on the later date only. The joiners appear to be confident of success, and point to the fact that they possess a local auxiliary fund of over £600, out of which, should the necessity arise, the grants from the general fund will be increased to £1 in each case. The general fund of the society is computed at £250,000. As a result of the deadlock all the public works of the city are at a standstill. These include the Cartwright Memorial Hall, the markets extension scheme, the Conditioning-houses, the Drummond Road Board Schools, and the new Central Fire Station. The masons in the Shipley district are out for an advance of ¼d. per hour—from 8¾d. to 9d. The operative joiners of Shipley, who are in the same society as the joiners in Bradford, are of course, also idle. Being a stone built town, there are, of course, very few operative bricklayers in Bradford. There are two societies, however, each claiming a small membership, and it is understood that these will hold by any action taken by the masons. The general opinion prevailing amongst the master builders is that, were it not for the clause in their notice which stipulates for the amicable working together of society and non-society men, there would be no question of a strike; and the feeling has been expressed by several of the masters that if it is the object of the operatives to have none but union men in the country, they are perfectly right in their contention. The estimated approximate number of men idle is 1,300—700 masons, 300 joiners, 150 labourers, 50 bricklayers and non-union men.

The Joiners of Northwich, Hartford and Mid Cheshire District have accepted the masters' offe of an increase of ½d. per hour on their wage c 8d. They demanded 9d. and a reduction of on hour per day in the time worked.

The Leicester Stonemasons have given notice t their employers to terminate existing contract with the view of obtaining an advance of fron 9d. to 10d. per hour, a reduction of half an hou a day and other concessions.

The Strike at Edmonton, which has been i progress for the last two or three months, in th brickmaking trade, has terminated, and the me have resumed work. The dispute occurred i consequence of the proposal of the masters t reduce the pay. Last year the remuneratio was 5s. 7d. per thousand for "stocks" and 6s. 8d per thousand for red bricks, and this season th masters offered 5s. 1d. and 6s. 5d. respectively These terms were refused by the men, wh we understand, recently threatened that unles matters were settled they would not go in at al this summer. The masters have now agreed t pay last year's rates.

New Patents.

These patents are open to opposition unti June 11th.

1900.—Drain Pipes.—7,824. R. Stanley Manor Court, and R. H. Smith, James Street both of Nuneaton. The object of this inventio is to make the socketted end of a drain pip denser and harder. The socket-die is divide into two halves (or into several segments which, by suitable means, can be withdraw outwardly or contracted for the purpose o compressing the clay.

1901.—Opal-glass Tiles.—458. A. J. Davis "The Firs," Amblecote, Stourbridge. The opal glass is coated on the back with a saturate solution of hyposulphite of soda, after which i is heated, rendering the soda a spongy roug mass capable of resisting acids. Grooves ar next cut into the backing to give a good "key" for the cement.

"Mack" Slabs.—3,853. A. Mack, Ludwig strasse, 6, Cannstatt, Wurtemberg, Germany This invention relates to slabs of gypsum, cement or other rapidly-binding material, in which woo strips are embedded in order to facilitate fixing The strips are directly visible on one side, an may be provided with nails or screws. They ar laid parallel to one another, and are dovetail i section.

The following specifications were published o Saturday last, and are open to opposition unti June 17th. A summary of the more importan of them will be given next week. The names i italics within parentheses are those of communi cators of inventions.

1900.—4,548, Mouchel, piles, columns, &c 9,664, Dollar, stable fittings. 9,808, Di Vallière, concrete buildings. 10,609, Hill door checks. 12,888, Chapman (*Berliner*), floo coverings. 15,547, Commoss, apparatus fo ornamenting surfaces. 15,830, Tuckwell manufacture of imitation marble. 19,901, Ratcliffe, treatment of wooden planks. 21,559 Picking, construction of fireproof brick or bloc for walls, partitions, &c. 21,950, Bosshard (*Soc. Anon. Parqueterie Franco-Hongroise*) parquet floors. 22,823, Vaughan & Paten Vulcanite Roofing & Asphalte Co., Ltd. construction of wood trellis girders for supporting large span flat roofs.

1901.—977, Matthews, non-conducting floors 2,944, Hendler & Reeves, apparatus for generating and burning acetylene and other gase 4,154, Allen, machines for cutting borders an trimming wallpaper. 4,788, Unterlechner device for fastening windows, doors, &c., in a open position. 4,851, Gremme, manufacture o coloured patterns or embossed or relief work.

Mr. William Lee, builder, of Bolton, died las week at the age of sixty-nine years. He wa president of the Master Builders' Association an Association of Plumbers, a Freemason and a Oddfellow.

Bricks and Mortar.

APHORISM FOR THE WEEK.

Art is consummate when it seems to be Nature.
—LONGINUS.

Our Plates. THE country cottage in the village of Barford, three miles south of Warwick, was erected last year. The site was an enclosed one, owing to the need of keeping the new house somewhat of the same height and the frontage line of the main village street, and in order not to encroach on the existing barn, intended for future stabling. An attempt was made to keep the building as simple and compact as possible. It is built of red brick, with natural fawn-coloured rough cast above the moulded brick-course at bedroom level, with battered rough cast buttresses at the four angles. The roof is covered with tiles, with half round ridge and hip tiles; the eaves have a plastered soffit of 14in. projection. The external window and door-frames are painted white with dark green doors and casements, the latter being filled with leaded lights. All internal woodwork is painted white. Wooden pilasters, with door-hood and wrought-iron stay-bar, form a feature of the front door on the street elevation. Internally the newel posts to the staircase are carried up to ceiling of bed room floor with moulded caps to support purlin in roof, a glimpse of the stairs being obtained from the little hall through the circular arch to passage. The small offices are shut off by double doors from the rest of the ground floor rooms. The best grates were supplied by the Carron Company. and were of the old-fashioned hob pattern with glazed bricks or tiles; the locks, door furniture and cast-iron bell-pull were supplied by Messrs. T. Elsley & Sons. The long and narrow garden at back is well supplied with shady trees, and is a mass of fruit blossom in the spring; in it are old brick walling for fruit trees, and enough lawn for a small croquet ground. The builder was Mr. Albert E. Sheasby, of Barford, and the building was completed last November from the plans, and under the supervision of the architect, Mr. Charles M. C. Armstrong, of 5, High Street, Warwick. The view shown from the garden side is from a pen and ink drawing by the architect.—Particulars of the baths at Plaistow will be found on page 259.

The Church of the Holy Innocents. THE Bishop of Kensington dedicated the second portion of the permanent church of the Holy Innocents at Hammersmith last Saturday week. The mission, which was originally started to ease the work in the adjoining parishes of St. John's and St. Peter's, was placed under the care of the present vicar, the Rev. H. C. Eden, in 1885, and when, in 1891, the first part of the new building was consecrated by Dr. Temple, a separate parish was assigned to Holy Innocents, with Mr. Eden as incumbent. The parish is thickly populated, most of its people being of the poorer classes, and to provide for the spiritual needs of the inhabitants the massive church shown in our illustration (see centre plates) has been provided. The building, which has been carried out from the designs of Mr. James Brooks, is now practically completed, and is capable of accommodating from 1,200 to 1,500 persons. The cost of the work already carried out has been £14,000, and of this sum £1,250 has yet to be collected. It is proposed, when funds will permit, to build a tower at the south-west angle of the church, standing apart from, but connected by, a small cloister with the main building. Within the church much of the decorative work yet remains unfinished, and the rood screen which the vicar and some of his old choir boys are carving from the design of the Rev. E. Geldart will add considerable to the appearance of the church when it is completed.

Annecy. The old-world town of Annecy lies on the borders of a sapphire lake. Though the sun may on hot afternoons rob the mountains of their colour, and clothe every blade of grass in glittering mail, it is powerless to rob the lake of its wondrous blue. Though the churches were ruined and the towns of the country round Annecy were destroyed during the great Revolution, much of the old character has been preserved, and one can still pass down streets that have been but little altered since St. Francis trod them. At Annecy canals run inland from the lake above referred to, the tongue of land forming a garden, so that from the town the blue of the lake is broken by trees. Facing what formerly was Le Pont de la Halle is the Palais de l'Ile (illustrated on p. 251), its prow-shaped chapel cutting the stream towards the lake. On a height above it is the castle, from which a street descends steeply to the town, its houses, originally of stone, have, in bygone times, shot forth wooden balconies and staircases so as to almost completely hide their original fronts. Below, most of the streets have stone colonnades. On market days the country followers arrange their wares under the arches. The town is bound in on three sides by the mountains which almost encircle the lake and form a shield against the north wind which here is said to never blow. Beyond the town, on the south side, flows the Fier, celebrated for its gorges.

Present-Day Design. At a meeting of the Edinburgh Architectural Society held on the 24th of April, Mr. A. F. Balfour Paul, president, in the chair, an address was given by the honorary president, Mr. Harold O. Tarbolton, at the commencement of which reference was made briefly to the art and work of the century just past. Mr. Tarbolton then mentioned that a predominant note of the present day was a restless striving after originality and quaintness, and this he was afraid would work no lasting good for art. Simplicity and restraint were much required. One of the great dangers of present times was the undue influence of pretty drawings. Examples of this were found in the system of competitions where specialists in the work were employed by the competing architects, and attractive drawings and perspectives were turned out which often conveyed false impressions to the minds of the judges. It was most desirable that academies should require the accompaniments of photographs of the actual buildings with the water colour drawings of the subject, the latter being no criterion whatever of the architectural value of the building. In students' training, sketching and measuring played an important part, and in this there was a danger of dwelling too much on "sketchy bits," and forgetting their position in the building and their proportion. In his busy life the architectural student often found little time for general reading, and was apt to become a one-sided man; if, however, he neglected his general education, in later years he would find himself quite out of touch with those with whom he would mix, and from whom he would obtain employment. Mr. Tarbolton then presented the prizes gained in the design competitions throughout the session as follows: Honorary President's prize of £10 for three designs, viz., "A Town House," "A Market Cross," and "A Reredos and Altar," Mr. George Willet; President's prize of £3 3s. for design for entrance gates to park, Mr. Wellesley Bailey; Vice-president's prize of £2 2s. for a design for a wood mantelpiece, Mr. F. C. Mears.

Marbles of the Parthenon. AT a meeting of the Hellenic Society held last week, Professor Ernest Gardner in the chair, Professor Charles Waldstein read a paper on "A Discovery of Marbles related to the Pediments of the Parthenon." The marbles in question were at Dresden, and were three statuettes, with two only, however, of which he proposed to deal, as the other was so imperfect. They were procured in 1892, and came either from Rome or through Rome. No special value was in the first instance attached to them. "Sie waren," it was observed to him, "in den Verkauf geworfen"—a sort of makeweight with other works of art. This apparent negligence should not be imputed as blame—the labour of cataloguing tended to blunt the keenest eye, and a man in inspecting such objects generally did so with some definite point of view, and this tended to make him lose sight of others. The statuettes, one of which was male, were considerably corroded, but there was no mistaking the splendour of outline. The female figure was even better than the male, which represented, he had little doubt, the Kephisos, the River God of the Parthenon. The lecturer illustrated his views by a succession of pictures on the screen, and showed the connection and resemblances between this statuette with the Illissus of the Parthenon. He traced also the conception of the River God and its successive developments from the days of Polygnotus to Roman times. He was fully aware of the extreme danger of over-confidence—the archæologist was not as the mathematician or votary of the exact sciences—and it behoved him carefully to discriminate between the certain and the probable, the barely probable and the possible. Exact agreement was not found either in the quality of work or in the materials of different parts of the Parthenon; nor was evidence of geologists and petrologists by any means conclusive, for he had known a petrologist to ascribe to different sources two specimens known to have come from the same place. Variations, therefore, of this character in these specimens from other work on the Parthenon were by no means conclusive against the opinion which he had formed, and the male figure seemed clearly borrowed from the Theseus of the Parthenon. The greatest dimensions of these statuettes were 35 centimèters and 20 centimètres.

Manchester Flats. SPEAKING recently at Birmingham, Councillor Parkins referred to the flat system, and said he had gone with a deputation to Manchester, and had come to the conclusion that the flat system there was by no means creditable to the Corporation. The places shown them by the officials were all right, but he made private inquiries, and found in the flats some of the worse cases of overcrowding he had seen. The rooms, too, were immensely dear, 3s. a week for one room 12ft. sq., and 5s. 6d. to 6s. for two rooms according to the storey. And yet these flats, although they were dear and inconvenient—especially those on the fourth and fifth floors—did not pay, and it was difficult to get to know what the actual loss to the ratepayers was. Moreover, the Manchester Corporation was not going to build any more of them because the people would not have them. The successful candidates in Manchester last November were those who placarded the walls with "No more barracks." Whatever was done in Birmingham the gentlemen who undertook it must have respect for the rights and the necessities of the classes they were providing for, and must take care that they were not erecting monuments of their own folly.

Galveston. THE last report of the British consul at Galveston describes the results to the trade and prosperity of the town of the storm and innundation of September last, and the efforts which have been made to repair the damage and restore the town to its original state. The estimated loss of property was nearly 3½ millions sterling, including the damage to Government property, such as the jetties, forts and stores. By the beginning of March last the port was almost completely restored, the wharves were repaired, and the grain elevators nearly so, but there was only one railway bridge in place of three; most of the damaged factories and commercial houses had resumed business, and enough had been done to the water, gas and electric lighting works to make them serviceable for the present. The damage to private houses had been largely repaired, and many new dwellings were erected to take the place of old ones destroyed by the storm. Curiously enough, in spite of the disasters to the town caused by the storm and flood, the trade last year was the largest ever done by Galveston, and amounted to over 18 millions sterling, against 15¼ millions the previous year, the exports of raw cotton forming almost the whole trade of the place. The increase last year was due to the high price of cotton; but even in regard to quantity, the exports last year were slightly beyond those of 1899. Imports decreased on account of the destruction for a time of the wharves and warehouses, but British trade increased all round, and was nearly 44 per cent. of the whole, Germany coming next with 26½ per cent.

THEODOLITE CONTOUR SURVEYING.

By G. A. T. MIDDLETON.

THE tracing of contour lines over hilly country is one of the most laborious operations which a surveyor is called upon to undertake; and if, as is usual, the levels be taken first, pegs being driven into the ground along the contour, and these pegs be afterwards surveyed, either with chain only or with theodolite, great errors may readily creep in and much trouble may be involved through the accidental removal of the pegs between the two operations. It is possible, however, to do the whole thing at one operation; and though apparently tedious, much time is saved in the end by adopting this course. It is difficult, and demands extreme care upon the part of the surveyor, who must be well acquainted with theodolite traversing with the assistance of the traverse tables, but on the other hand is capable of absolute proof of its exactitude.

Two field books must be used simultaneously. One is an ordinary theodolite traverse book, with columns for the line, its declination east of north and its length (these being entered in the field); for the latitude (N. or S.) and the departure (E. or W.), given in units of distance from each theodolite station in succession; and for the total latitude and total departure from the first theodolite station. These are calculated by the aid of the traverse tables, sometimes in the field, but more generally in the office.

The other book is an ordinary levelling book, with the two columns usually devoted to rise and fall replaced by a single column devoted to entries of the collimation plane level at each setting of the instrument.

A theodolite only is used, the vertical arc being clamped at zero and carefully levelled at each setting up, so that it becomes practically a level with which horizontal declinations from the meridian can be accurately read. If it be fitted with stadia points for tacheometric determination of distances, the work is greatly facilitated—so greatly, that they are almost essential.

The theodolite stations, not being necessarily on any one particular contour, can generally be selected in succession, so that the distances between them can be accurately measured along a straight line by means of the chain without encountering serious obstacles; but the contour line, in its windings, will frequently take the staff-holder into positions whose distance from the instrument can only be measured by means of the stadia points, without an infinity of unnecessary trouble.

In the example which has been taken for illustration, the first position of the instrument (Station 1) was selected within view of the bench mark, whose height (11·72ft.) above datum level was known. At that position, the vertical arc was clamped to zero, the instrument carefully levelled, the horizontal vernier clamped to zero, and the whole instrument revolved horizontally till the north point of the compass-needle also pointed to zero, and then clamped. The horizontal vernier was then released, and the telescope directed to a levelling staff held at the bench mark, when the vernier was adjusted by means of its tangent screw and clamped.

The staff reading was 4·45, and as the instrument had been properly levelled this was entered as the back sight in the level book, the height 11·72 being entered as "height above base," and the words "bench mark" being entered in the distance column. By adding the reading and the known height of the bench mark together, the total height of the collimation plane above base (or datum) is ascertained to be 16·17ft., and this is entered accordingly.

It being desired to trace a contour line at a height of 10ft. above datum, this height (10·00) is entered in the second line of the level book as "height above base" with the entry "points on 10ft. contour" in the "remarks" column. By deducting this 10·00 from the collimation level of 16·17 it is ascertained that so long as the instrument remains on Station 1 the staff reading at all points on the 10ft. contour must be 6·17, which is accordingly entered in the "intermediate" column.

TRAVERSE FOR CONTOUR SURVEY.

The staff-holder is now sent to some position which looks as if it would give this reading, the horizontal vernier is again released, and the staff is read. If the reading exceed 6·17 the holder is signalled to move up the hill; if the reading be less than this he is motioned to move downwards, and so on, until it is obtained; though for many purposes it is unnecessary to get a reading nearer than ·02 to that which is theoretically correct, so small an error being often due to the presence or absence of a tiny stone under the heel of the staff. The point so ascertained may be called A, and so entered in the "distance" column of the *level book*. At the same time its actual distance from the theodolite station can be ascertained by means of the stadia points, and so entered in the second line of the *traverse book*, as from 1 to A = 91 links; while consultation of the vernier will show the declination of this line from north to be 50deg. 29min. The latitudes and departures are then worked out in the usual way; but as these are calculated as from Station 1, no correction is necessary, by addition or subtraction, when making the final entries in the columns for totals. The traverse book is finally rendered perfectly clear by entering in the "remarks" column that A is a point on the 10ft. contour.

Plotting of Contour Survey.

It is well for the sake of clearness to use numerals to designate theodolite stations, and letters to denote points on the contour, or *vice-versâ*.

Examination of the two field books and of the plotted plan should be sufficient, with the above explanation, to show any careful student how the rest of the work is done. The only further difficulty occurs at the change of theodolite stations, when fore and back sight entries have to be made in the level book in the usual way; and when it must be borne in mind that the total traverse distances from Station 1 of, say, Point D, are found by comparing the distances of that point from the station (Station 2) from which it was observed with the totals of Station 2 from Station 1. Thus Station 2 is 70·00 south of Station 1, while Point D is 78·23 north of Station 2; so that, in the totals, Point D is 8·23 north of Station 1.

Law Cases.

Delay by Sub-Contractors: Important Appeal Case.—The case of *Leslie & Co., Ltd.* v. *The Managers of the Metropolitan Asylum District* was heard in the Court of Appeal on April 29th. The question arose upon a contract (dated July 23rd, 1895) entered into between the plaintiffs and the defendants for the erection of a hospital for infectious fevers at Hither Green, Lewisham. A great part of the work had been let out to sub-contractors and experts, including Messrs. Doulton, of Lambeth, and Messrs. Berry & Sons, of Westminster. The question was, Who was to be responsible for alleged delay on the part of these sub-contractors? The contract provided that the plaintiffs should, at their own cost, execute "the works" shown on the plans, including the chimney-stacks and heating apparatus. The time in which the work was to be completed was two years, and the price to be paid was £210,688. Mr. Hall was the architect. The contract contained the following clause relating particularly to the chimney-stacks: "The contractors shall provide the sum of £137 10s. prime cost for each central stack of flues in large wards above the level of the ground floor. These stacks will be of faience, fire-clay, terra-cotta and concrete, and, including hearths, grates, &c., will be supplied, fixed and finished complete by a specialist potter. The contractors are to supply all necessary scaffolding, plant, water and hoisting." The plaintiffs communicated with Messrs. Doulton, who undertook to do the necessary work. Part of the claim in the action arose from the alleged delay on the part of Messrs. Doulton in doing this work. A second head of claim arose from a sub-contract for the supply of the necessary steam and hot-water apparatus. The contract contained the following clauses relating particularly to this apparatus: "The hot-water supplies to baths, lavatories and sinks, except where otherwise specified, the hot water, heating, &c. . . . will be done by specialists, but the contractors are to attend on, cut away for and make good after them. The hot services will be brought by the specialist to the following points of outlet (specifying the same), but the valves thereon are to be supplied and fixed by the contractors. Note.—All hot-water services, as well as heating apparatus, . . . will be done by specialists." On February 2nd a sub-contract was made between the plaintiffs and Messrs. Berry & Sons by which the latter agreed to supply this apparatus for £11,900. It was alleged that Messrs. Berry had also been guilty of delay in executing this work. The delays of the sub-contractors were owing to the difficult and special character of the work. Owing to these alleged delays the plaintiffs could not complete their works and get the architect's final certificate and payment accordingly. They therefore claimed damages on the footing that there was an obligation upon the defendants to see that the work was done by the specialists and sub-contractors within a reasonable time. The claim was referred to Mr. Pollock, one of the Official Referees, who considered the contract and voluminous correspondence involved in the case. Counsel for the defendants contended that they were not liable on the ground that Messrs. Doulton and Berry & Sons were sub-contractors with the plaintiffs, and any claim for delay lay against them, and not against the defendants. The learned referee held that the defendants were liable to the plaintiffs, and the defendants appealed from that decision to the Divisional Court, which held that the plaintiffs could not impose upon the defendants the consequences of the delay of the sub-contractors. The plaintiffs appealed. —The Court dismissed the appeal.—The Master of the Rolls said that it appeared from the contract and the specifications that the plaintiffs were to provide everything to make the hospital complete, and that, although specialists were to execute some of the works so contracted to be executed and provided by the plaintiffs, these latter works formed part and parcel of the entire works, for which the defendants were to pay the plaintiffs the sum of £210,668, the plaintiffs out of this sum paying the specialists. He came to the conclusion that the defendants could not be liable to the plaintiffs for the delays of Doulton & Co. The defendants had never contracted with Doulton & Co. The persons who contracted with Doulton & Co. were the plaintiffs, and the plaintiffs alone. The defendants throughout studiously avoided contracting with Doulton & Co., who were sub-contractors of the plaintiffs or their agents. Doulton & Co.'s work was work which the plaintiffs had contracted with the defendants to provide for in the £210,688. The defendants never paid Doulton & Co. one penny for their work, and were never under any liability to do so. Doulton & Co. were paid by the plaintiffs, and by no one else. It seemed to him that the Divisional Court were quite correct in holding that the defendants were not liable to the plaintiffs for the delays of Doulton & Co. If anyone had a remedy against Doulton & Co. it was the plaintiffs and not the defendants. It was said that the plaintiffs only contracted with Doulton & Co. so as to get rid of the necessity of the defendants having to obtain the consent of the Local Government Board to a contract between themselves and Doulton & Co., which would have been required if the plaintiffs had not contracted with Doulton & Co. However that might be, there stood the plaintiffs' undoubted contract with Doulton & Co., upon which beyond doubt the plaintiffs could sue Doulton & Co. and the defendants could not. It was next argued that if this was so, and the plaintiffs sued Doulton & Co. for delays, they would do so as trustees for the defendants, and that if the plaintiffs recovered damages from Doulton & Co. they would have to hand over the damages recovered to the defendants. His Lordship did not agree. The truth was that there was no trust at all. How could the plaintiffs be trustees for the defendants for what they might recover from the specialists, their own sub-contractors, who were merely doing the work which the plaintiffs otherwise would have had themselves to carry out under their contract with the defendants. In his Lordship's opinion there was no substance in the contention. With regard to Messrs. Berry & Sons, the above remarks applied to their case, it being, if possible, a stronger case than Messrs. Doulton & Co.'s against the plaintiffs' contention. The appeal must, therefore, be dismissed with costs. The Lords Justices delivered judgments arriving at the same conclusion.

Huddersfield's New Theatre: The Architect's Successful Claim.—In the King's Bench Division of the High Court of Justice last week the case of *Matcham* v. *The Northern Theatres Co., Ltd.* was heard. This was an action brought by Mr. Frank Matcham, architect, against the defendants, who have theatres in several towns in the North, to recover £1,059, his fees for preparing plans, specifications, &c., for a new theatre at Huddersfield. Defendants denied liability. The plaintiff's case was that in May, 1899, he was instructed by the defendants to prepare plans, specifications, &c., for a new theatre which they proposed to erect at Huddersfield. He carried out the necessary work, and he submitted that he was entitled to recover £1,059, being 2½ per cent. on the estimated cost of the theatre (£22,183), £500 for getting out quantities, and £5 1s. 6d. for railway fares. The defendants contended that they were not liable, as the plaintiff did not carry out their instructions. They said that the plaintiff was requested to prepare plans, &c., for a theatre to cost £15,000, whereas the building which he designed would have cost £28,000 to erect. In those circumstances, defendants said, the plans were of no use to them, and they were not liable to pay for them. Plaintiff denied that the price of the building with an engine room and water tower was limited to £15,000, and said that with economies the work could have been carried out for £20,000. The jury found for plaintiff for £325. Judgment was entered accordingly, with costs.

Correspondence.

St. Sidwell's Church, Exeter.

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—Permit me to say that we do not accept Sativola as our dedication saint (see p. 223 of BUILDERS' JOURNAL for April 24th). It is Sidwell pure and simple, although no doubt the monks of the Middle Ages sometimes Latinised it into the form given by your correspondent. Still, I have it from my friend the Rev. Prebendary F. C. Hingeston-Randolph—certainly the most learned man on such matters in the county—that in Bishop Stafford's Register (A.D. 1395-1419) the apples in the garden of the dean and chapter at *St. Sidwell's* are referred to. The late Professor Freeman says in his "Exeter" (1887): "There is a local legend of St. Sativola. or Sidwell, whose name lives in the dedication of a suburban church. Her story seems to be placed late in the seventh century, and her worship is anyhow older than the time of Æthelstan."

The Rev. S. Baring-Gould in his recently-published "Devon" (1899) tells us that Athelstan came to Exeter in A.D. 926, and gave to the monastery of SS. Mary and Peter (afterwards the cathedral) the relics of St. Sidwell. "This, he adds, "was a local Saint, of whom very little is known save that she was the sister of Paul, who became abbot and bishop of Léon, in Brittany."

It is quite true, of course, that the original church (probably British) has long since disappeared, but the fine Beer stone arcades of the fifteenth-century edifice, and the western tower of Heavitree stone are still in existence. The tower, next to the old Roman towers now doing duty as transepts to Exeter's fourteenth-century cathedral, is by far the finest of any date in or about the city. In the belfry the father of Sir Walter Raleigh was confined a prisoner during the disturbances of his time, and the upper part of the tower itself was blown off by an accidental explosion of stored gunpowder. The damage was repaired with bricks. The main part of the church was rebuilt early in the last century by the late Mr. William Burgess, who also erected a wooden spire and put it upon the western tower, surmounting it with an ancient weather-cock that had formerly done 268 years' continuous service upon the low spire over the north transept tower of the cathedral. This fine specimen of ancient copper-work, upon an iron vane, was placed upon the cathedral spire in 1484, and continued there until 1752, when, with the spire, it was removed. When St. Sidwell's spire was built in 1812 the then Dean and Chapter presented the old relic to our parish, and it stood there upon its spire, doing honest work, day and night, until taken down on May 2nd, 1899. Although 417 years old, it is now just as good as new; and, when the present repairs to St. Sidwell's, under the able direction of Mr. E. H. Harbottle, F.R.I.B.A., the cathedral architect, are completed, it will again surmount the brave old tower. The repairs in hand practically mean a conservative renovation of the tower. All the brickwork has been removed, and new stonework will be substituted.

Thus, ere another year is passed, our tower will again be what it was full five hundred years ago, with the vane—of which every St. Sidwell's man is so vain!—once more perched securely and proudly upon the top thereof.—Yours truly,

HARRY HEMS.

A New Style.—A north country newspaper, in describing a church, recently stated that "the style is certainly unique, reminding one, if we are not mistaken, of the Besantine period" (!).

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

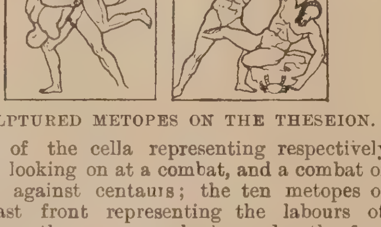
The Theseion at Athens.

GRAYS.—R. J. T. writes: "I am drawing from Phené Spiers' Orders the Theseion at Athens, in which only one carved metope is given. I should like to include the two next in order. Kindly name a book in which they may be found, and also give a description of the building."

The "Theseion" is one of the best preserved monuments of ancient Greece; yet its early history is unknown, and its dedication little more than a matter of conjecture. Archæologists are however agreed in rejecting its identification with the Theseion mentioned by Aristotle in the recently discovered "Constitution of Athens," by Pausanias in his "Description of Greece," and by Plutarch in his "Lives." On grounds both topographical and architectural the theory (first advanced by Pervanoglu, and supported by the veteran Dr. Dörpfeld) of its dedication to Hephœstus, is now generally accepted. From certain peculiarities in the details Dr. Dörpfeld concludes that the building is just a little later than the Parthenon. For instance, the continuous moulding, devoid of guttæ, under the frieze of the cella, and the base moulding around the walls, betray, in Dr. Dörpfeld's opinion, a disregard for the strictness of the Doric type, which would hardly, he thinks, be attempted before the erection of the Parthenon.

Notwithstanding the general acceptance of the "Hephœstus" theory, the fact remains that the sculptured metopes are entirely devoted to the exploits of Theseus and Hercules; yet, from the attachment marks on the back of the pediments, it is known that these spaces were not only filled with sculpture, but Dr. Sauer believes that from these marks he can make out the subjects! in one case, the birth of Erichthonius, son of Atthis and Hephœstus, and in the other the rising of Hephœstus from the sea after his fall.

The disposition of the sculptures remaining on the building is as follows: the east and west friezes of the cella representing respectively deities looking on at a combat, and a combat of Greeks against centaurs; the ten metopes of the east front representing the labours of Hercules—these are much decayed; the four metopes on the north and south sides respectively, at the ends nearest the east, devoted to the exploits of Theseus. The remaining metopes are quite plain, and have never been filled with sculpture. The whole of the sculptured metopes are engraved in the Italian *Monumenti dell' Instituto Archæologico;* also in "Stuart and Revett." We give rough notes of two from the north side: Theseus killing Cercyon, and Theseus killing Sciron. For further particulars of the temple, see Penrose's "Principles of Athenian Architecture," Harrison's "Mythology and Monuments of Ancient Athens," Stuart and Revett's "Antiquities of Athens," and the BUILDERS' JOURNAL for 1899. J. A. M.



SCULPTURED METOPES ON THE THESEION.

Taking off Brickwork Quantities.

CLAPTON. — R. N. E. writes: "Kindly answer the following question on brickwork: The general description of a house is as follows: 18in. work two lower floors, 14in. work two upper floors, in red facings, backed in with stocks in mortar, gauged segmental arches, with moulded labels, plain gauged pilasters 18in. face, $2\frac{1}{4}$in. projection, moulded string-course 3in. deep, moulded cornice five courses deep, 12in. projection; the two latter breaking round the pilasters, and scalloped aprons to windows. The red facings to be neatly pointed with a weather joint. State minutely how you would measure all the brickwork in connection with the front."

Excavation Concrete and Walling. Collect mean length of four walls "on waste" by length out to out, added to breadth in clear, and twicing the quantity. Transfer to dimension column for length of main items.

Footings. 18in. wall = 2-b. wall = four half bricks in thickness ∴ four courses of footings = 1·0 depth. This will be the second measurement of first item, the length being first. Average the footings on waste by adding width of top course to width of bottom and halving. This will be entered in description column as "$3\frac{1}{4}$-b. ftgs."

Lower Walls. The next item will be the same total length, unless the front wall only is to be dealt with. The mean length would then be the measurement from outside one end to inside the other end, but the actual length would be taken, in view of the remainder of the question, as the length out to out on face. The height from top of footings to top of wall plate on set-off would be the second measurement in the item, and the description would be reduced brickwork in mortar to 2-brick wall, generally entered simply as "2-b. wall."

Damp-proof Course. The length will be same as last item and breadth 1ft. 6in., the description being taken from specification, either Tylor's glazed perforated damp-proof course, a double course of slates in cement, $\frac{1}{2}$in. Seyssel asphalt, or whatever may be desired. The former alternatives to be described as "Measured nett, allowance to be made for cutting and waste."

Upper Walls. If the whole of the brickwork were being taken the length would now be increased by 18in. to allow for $4\frac{1}{2}$in. set-off on four walls, but if the front wall only is to be taken the length will remain the same as for the lower walls. The height will be from the termination of the previous measurement of height to the top of upper wall plate. The description will be "$1\frac{1}{2}$-b. wall."

Facings. For the length take the same length as before, and for height take from ground line to under side of cornice; describe as "Extra only on stock brickwork for best pressed red facing bricks (name)."

String-Course. Take same length as last item, and describe as "Extra labour and material on facings to 3-in. moulded string—course continued round pilasters."

Cornice. Take same length as last item, and describe as "All labour and material in forming moulded brick cornice five courses deep, 12in. projection as sketch." With "No. extra to bonding and forming internal and external mitres to ditto."

Pilasters. Take for width the actual width plus two returns = 1ft. $10\frac{1}{2}$in., and for height the distance from ground line to under side of cornice, and times it for the number of pilasters. Describe as "Extra labour and materials over facings for gauged work in bonding and forming plain pilasters 18in. by $2\frac{1}{4}$in."

Deductions. Begin at the top and work downwards For windows generally, take width in clear by height to springing-line, and describe as "Ddt. $\frac{1}{2}$-b. wind. op," timesing the item for the number of windows to which it applies. If the reveal should be more than $\frac{1}{2}$-b. wide the description must be amended accordingly. The next item will be the deduction for the remainder of the brickwork in the same openings. The width will be $4\frac{1}{2}$in. more on each side to allow for sash frame, and 3in. more in height to allow for head of sash frame. In the description the thickness will be whatever is required to make up the total after deducting the reveal. No further deduction is made for splayed jambs. Door openings will be dealt with in a similar manner, allowing 2in. at sides and head beyond the reveal. In deducting the facings the width will be lessened by the breadth of reveals.

Arches. Take the mean length by the width on face plus soffit, and describe as "Extra on facings for rubbed and gauged segmental arches."

Labels. For the labels over windows take length, and describe as "Extra labour and material for forming moulded labels over window arches as sketch."

Aprons. Give dimensioned sketch, and describe as "Extra on facings to labour and material forming scalloped aprons in gauged brickwork to windows, projecting $2\frac{1}{4}$in. as sketch."

Relieving Arches. These should be numbered, and described as "Extra labour only in rough relieving arches to ft. in. opening (average), and in. soffit including all cutting."

Rough Cutting to splayed window jambs. Measure whole surface cut per ft. super.

Fair Cutting. Per ft. run as "Fair-cut skewbacks," or circular as "Circular fair-cutting to brickwork over arches."

Pointing. Super the whole area of wall with reveals, soffits, returns and moulded work, and describe as "Rake out and point brickwork with weather joint." This is according to the question, but is unusual. The arches, pilasters and aprons should be tuck-pointed.

HENRY ADAMS.

Cost of Building.

ST. ALBANS.—ANXIOUS writes: "What price per cub. ft. should be allowed for (1) a brick mission church with stone dressings, in Late Decorated style, tiled roof, no tower, plastered inside, with wood-block flooring; (2) a three-storey Board school for 1,200 children, plain brick facings; (3) a one-storey school for 400 children, plain exterior?"

Schools, churches, chapels, lecture halls, town halls, technical institutes and public libraries cost from 6d. to 1s. per cub. ft., according to the solidity and amount of ornament. It is difficult to price without seeing the drawings or knowing the locality; but, approximately, say for the church described 9d. per ft. cube, for the three-storey Board school 8d., and for the one-storey school 7d. Possibly each might be 1d. less. HENRY ADAMS.

Weale's Architectural Books.

WONERSH.—H. S. G. writes: "I wish to obtain the following books of Weale's Scientific Series: (1) 'Modern Architecture,' by W. H. Leeds, Talbot Bury and E. L. Garbett; (2) 'The Art of Building,' by Edward Dobson; (3) 'Cottage Building,' by C. Bruce Allen; (4) 'Construction of Roofs of Wood and Iron,' by W. Tarn; (5) 'Hints to Young Architects,' by G. Wightwick; (6) 'Practical Bricklaying,' by A. Hammond. Where can I obtain these books?"

The above-named books can be obtained from Mr. B. T. Batsford, 94, High Holborn, W.C. Their prices are as follows: (1) 6s.; (2) 2s.; (3) 2s.; (4) 1s. 6d.; (5) 3s. 6d.; (6) 1s. 6d.

Weight of Iron Columns.

LANCASHIRE.—WEIGHTS writes: "What is the most expeditious way to calculate the weight of a tier of cast-iron columns as per sketch (not reproduced)?"

This query is not sufficiently explicit. It is not clear whether a dimensioned drawing is provided and the weight is required for the bill of quantities, or whether the dimensions themselves, thickness, &c., are required. The base plate shown is unusual and inconvenient in form, and there are other faults in the design. The weight may be estimated roughly by allowing 4 cubic inches to the pound. More exactly, a cubic inch weighs ·261b., or a square foot 1in. thick weighs $37\frac{1}{2}$lb. HENRY ADAMS.

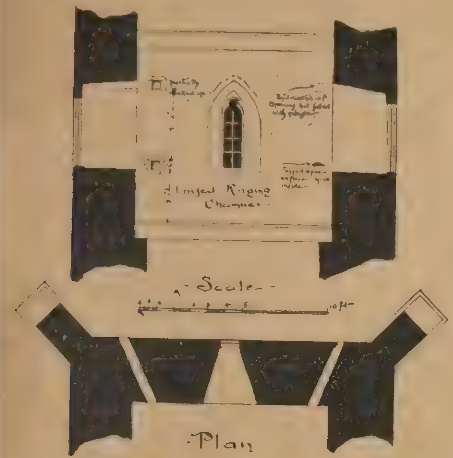
Surveying and Draining Land.

CHERBORNE.—E. J. C. writes: "What is a reliable and simple method of procedure in making a survey of a field whose capacity is approximately from 12 to 14 acres, the boundaries being somewhat irregular and in places undefined? The land in question is proposed to be laid out for building purposes with new roads constructed as shown on sketch (not reproduced), and then cut up into smaller lots and sold. What is a suitable scale for plotting this to? There is a fall of about 6ft. to existing road, the boundary of field at this point being 5ft. above it, and the field generally very wet. Do you think this should be drained before developing it. I contemplate putting a main drain of 6in. agricultural pipes down centre with 4in. branches into same, these latter spaced at a distance of 21yd. apart or thereabouts. Do you think this would have a beneficial result on the land?"

The articles on surveying on p. 264 of this issue, and on page 180 of our issue for April 10th last will provide you with some information, and you should consult Mr. Middleton's "Surveying and Surveying Instruments." (Price 3s. 9d. B. T. Batsford). The usual scale for plotting out estates is 44ft. to the inch. It is certainly an absolute necessity to drain the land before building on it, but as the draining is only temporary we would advise that channels be cut, which, with the fall there is, should give good results.

Use of Channels in Church Tower.

LONDON, E.C.—INQUISITOR writes: "Kindly give me an idea as to the use of 6in. by 6in. channels in the first floor of a church tower in Kent, as shown by the accompanying sketch. There are also indications of others on left side (not shown), but none on the right. The lowest channel is 25ft. from the ground. They are of the same size on the outer face, and have a slight rise from the inside."



This is a difficult question to answer satisfactorily, and the best that can be done is to surmise. That the holes were intended for the support of beams or putlogs may be dismissed on account of their diagonal arrangement on plan. They were, however, apparently left, when the tower was built, for some deliberate purpose; but they are not the right shape for arrow slits, and the fact that they rise towards the outside is against their use for the discharge of weapons of any sort, though church towers, especially near the coast, were frequently fortified and reserved as last places of defence for the village folk in the event of attack. Towers were also frequently used both as beacons and as look-outs; and small holes of this sort, if directed towards other beacon towers or eminences, might possibly have served for outlook, though they are low in the tower for such a purpose. Another suggestion is that they might have served for astrological or astronomical observations, but they are too nearly horizontal for this to be probable. Of all suppositions the most likely is that the chamber served as a large dovecote, these holes being the entries for the birds. If we read the plan correctly, they occur only on its southern and western faces, so that the birds could enter in safety, except during direct south-westerly gales, and even then some shelter would be afforded by the south-west buttress. The question arises as to whom the manorial rights belonged to, as a vicar would hardly be privileged to keep so large a number of pigeons as could be sheltered in a church tower unless he possessed rights over neighbouring corn lands. Thus, if the church has a large chancel, it was probably monastic, and the neighbouring lands belonged to the monastery, and they might have belonged to the ecclesiastical patron of the living; and in either of these cases the probability of the tower having served as a dovecote becomes almost a certainty. On the other hand, if the land around used to belong to antagonistic laymen, the probability is reversed. G. A. T. M.

Plastered Ceilings.

HASLAND, CHESTERFIELD.—BAFFLED writes: "I shall be glad to have your opinion on the following: My parents built a house which was finished fourteen months ago. The ceilings, which were set white, are now covered with cracks (not open ones), although under the first-floor tiled hearths, which are carried by brick arches, the cracks are open and plaster appears like falling. I also notice that the ceilings are marked with yellowish-brown spots, and that the course of the laths can be distinguished when standing in certain positions. The house is in other respects soundly built, and was carried out by an architect with a great deal of experience. The joists in each first-floor room have one row of solid bridging to 7in. by 2½in. joists, 12in. apart. Do you consider ceilings 'set white' to be satisfactory? What thickness should two-coat plaster work be? My opinion is that the small cracks are caused by the ceilings being 'set white,' which dried too quickly (joists unfirmly fixed would not cause cracks all over, and on the first-floor ceilings), the large open cracks under bedroom hearths through arches giving way, the yellowish-brown spots by the lath nails rusting and the course of laths showing through plaster, because the latter was not the proper thickness (it had two coats). I should be glad if you could give any other reason. The ceilings are also very black, as if they had not been cleaned for eight or nine years. We use gas with a ¾in. main and No. 4 burner. Other people using same gas are not so troubled. What do you suppose is the reason of this?"

The theories given to account for effects produced in the ceilings seem to us reasonable. Bad materials were doubtless used and the work scamped. The work being only of two coats. *i.e.*, the floating brought up from the laths in one coat and then set, would account for the lines of laths showing, both by the thinness of the plastering and also by the dust, laying on the plaster between the laths, forming a dirty background. This collecting of dust on thin plaster where it is open between the joists also accounts for joist lines being seen, and can be prevented by putting a backing of paper on. The two-coat work would also partly account for the cracks. Plasterwork should not be of two but of three coats, that is to say, as usually specified by "lath, render, float and set." Ceilings "set white" should be satisfactory if properly done. We should think that the blackness of the ceilings was caused by defective gas burners, bad materials being used in the plaster, the plaster not being set upon a proper floated surface, and the dirt and dust above, which we have just referred to.

Defect in Quantities.

REX writes: "A building contractor has signed drawings, specification and quantities, and also building agreements in which he undertakes to complete the building in accordance with specification, drawings, and quantities; the latter were prepared by the architect and paid for by the builder. On completion of the work, various omissions are discovered in the quantities, but the work has been executed in accordance with the specification and drawings. For the cost of this work, omitted from the quantities but included in the specification and drawings, has the builder any remedy against the building owner or against the architect?"

We think the builder cannot establish any claim against the building owner as the quantities were prepared by his servant, he having been paid by the builder. The question would not have arisen had the builder engaged an independent quantity surveyor; but as the architect to all intents and purposes acted in the same manner, the builder is bound by his action, and should only claim against him for negligence. It is usual when the preparation of the quantities is not paid for the builder to disclaim any responsibility for inaccuracy in the quantities; this safeguards both building owner and architect, but bears hardly upon the builder, who if he devotes labour to checking the quantities is unrewarded, or, if he assumes them to be accurate, loses if they are not so. There would appear no adequate remedy for this under the present system. D.

The Attention of Readers is directed to the particulars of our new schemes of insurance given on page 270 of this issue.

Engineering Notes.

Messrs. Keiller's New Works, Silvertown, Essex, are being ventilated by means of Shortland's patent exhaust ridge ventilators, supplied by Messrs. E. H. Shorland & Brother, of Manchester.

Ramsden Dock Improvement.—The work in connection with the lowering of the sill at Ramsden Dock lock has now been completed. The work of removing the dam is proceeding apace, and the third row of struts has been reached.

Durban Harbour.—The harbour engineers have prepared a scheme for the improvement of the port at a cost of nearly £3,000,000. The scheme includes four miles of quay works, and makes provision for a graving dock. The improvements will quadruple the present capacities of the port.

Middlesex Tramway Schemes.—The Middlesex County Council has notified the Light Railway Commissioners of an intention to apply for powers to construct electric tramways from Tottenham, through Woodgreen and Friern Barnet, to a point near Colney Hatch Asylum, and from Highgate Archway, the London boundary, along Archway Road and Great North Road, to the Hertfordshire boundary near Whetstone. The total cost will exceed half a million, and the council has entered into a contract with the North Metropolitan Tramways Company to work the whole system. An extension of an important nature will be made, a spur line being contemplated from Highgate railway station to the Muswell Hill entrance of the Alexandra Palace and Park. It will probably connect with the line at Colney Hatch. The Finchley District Council contemplate a tramway of their own to join the proposed Finchley and Hendon lines.

The Institution of Civil Engineers.—At the annual general meeting of this Institution last week, Mr. James Mansergh in the chair, the result of the ballot for the election of officers was declared as follows: President, Mr. Charles Hawksley; vice-presidents, Sir William H. White, Mr. J. Clarke Hawkshaw, Mr. F. W. Webb and Sir Guildford L. Molesworth; other members of council, Mr. James Barton, Mr. Horace Bell, Sir Alexander Binnie, Mr. B. Hall Blyth, Mr. C. A. Brereton, Mr. T. Forster Brown, Mr. R. Elliott Cooper, Mr. G. F. Deacon, Mr W. R. Galbraith, Mr. G. H. Hill, Mr. J. C. Inglis, Dr. Alexander B. W. Kennedy, Mr. A. G. Lyster, Mr. J. A. McDonald, Mr. E. P. Martin, Mr. William Matthews, Mr. Alexander Siemens, Mr. Thomas Stewart, Mr. J. I. Thornycroft, Professor W. C. Unwin, F.R.S., Sir E. Leader Williams, Mr. C. W. Darley, M. E. P. Hannaford, Mr. William Shelford, Mr. John Strain, Mr. F. R. Upcott. The council of the Institution of Civil Engineers have made the following awards for papers read and discussed before the institution during the past session: A George Stephenson medal and a Telford premium to Mr. Harry E. Jones; Telford medals and premiums to Mr. G. A. Hobson and Mr. E. Wragge; a Watt medal and a Telford premium to Mr. Joseph Husband; Telford premiums to Mr. J. T. Ford, Mr. L. L. Buck, Mr. W. H. Stanger. Mr. B. Blount and Mr. W. J. Doak; Crampton prize to Mr. E. Sandeman.

A New Gas.—A committee of the House of Commons have had under consideration the Mond Gas Bill, which authorises the formation of a company, with a capital of £1,000,000, to supply gas manufactured under patents taken out by Dr. Ludwig Mond for power and heating purposes in the large industrial district 100 square miles in extent to the north-west of Birmingham. The process of manufacture is as follows: A mixture of air and steam is forced through the burning slack used for the manufacture of the gas, with the result that the whole of the combustible matter in the slack, including the coke, is converted into gas. The ordinary cost of slack was 6s. a ton, and every ton used yields a quantity of sulphate of ammonia which can be sold as a fertiliser for 4s. 6d., so that the actual cost of fuel is 1s. 6d. a ton. The gas cannot be used as an illuminant. Five manufacturing stations are proposed to be erected in different parts of the Black Country, and a network of 2ft. 6in. mains laid down. The promoters hope that the demand for the gas will reach 84,000,000 cubic feet every twelve hours. At 2d. per 1,000ft.—the price at which they expect to be able to supply the gas—as against the average rate of 2s. now charged in the district, they will obtain an income of £210,000. The nett cost of production and distribution, after deducting the amount received for sulphate of ammonia, is estimated at £85,000, leaving a profit of £125,000. The Bill was opposed by the Corporation of Birmingham, about one-half of the other local authorities in the district, and several gas and electric lighting companies. A further objection urged was that the gas was of a highly poisonous character, and, as it must be distributed at a very high pressure, there must be considerable leakage. The promoters reply that the gas is not to be used for domestic purposes, and that therefore there will be no danger of leakage in private houses. Any leakage outside would soon be discovered on account of the distinctive odour of the gas, which is described as being "like that of ordinary coal gas which had been buried for some time and dug up again."

Mr. Ernest Kilburn Scott, M.I.E.E., A.M.I.C.E., has taken up the position of engineer and manager (United Kingdom, Colonies and Egypt) to the International Electric Co. of Leige, the London offices being at Clun House, Surrey Street, Strand, W.C. Besides the ordinary run of electric lighting work, Mr. Scott proposes to give special attention to the application of continuous and multiphase motors to machine driving in factories, iron and steel works, &c; also to mining work, electric traction for tramways and railways and to long-distance power transmission. The International Electric Company of Leige is the most important electrical concern in Belgium, and was founded in 1889 by Mr. Henry Pieper, general director. The manager and technical director, Mr. G. J. Melms, was with the General Electric Co. of America for many years, and as manager for Messrs. Brown, Boveri & Co., Frankfort, personally supervised the construction and operation of the Frankfort Municipal Electric Station—one of the largest central power stations in Europe—having a single-phase motor load of upwards of 6,000 h.p., including three motors of 750 h.p. for working the city tramways. Under Mr. Melms's management, the International Electric Co. of Leige have of late years taken a prominent position in the electrical world, having created many new and special forms and types of machines for the application of electricity, and also supplied machinery to numerous large and well-known firms in the United Kingdom.

The Production of High Temperatures.—By Dr. Hans Goldschmid's process very high temperatures are produced by the combustion of aluminium. This process depends on the intense heat developed by the chemical reaction when a mixture of finely powdered aluminium and oxide of iron is ignited. This reaction is very easily started, but it does not take place if the mixture, which has been named "thermite," is wet, nor does it occur spontaneously or by percussion. But when once begun it proceeds with extreme rapidity, and in the course of a few seconds a mass of molten iron and corundum is obtained, the temperature of which may be 3,000 degs. Centigrade. The application of thermite to welding steel tubes and rails was illustrated recently at a demonstration in Pimlico. The tubes—which may be of any size up to 6in. or 7in.—have their ends cut square and pressed together by clamps. The place to be welded is then enclosed in a small sheet iron box with a jacket of wet sand, and the thermite, ignited in a crucible, is poured into the box. The result is that the ends of the two pipes are quickly heated up to the welding temperature and thus united, the clamps being slightly tightened at this stage to force the ends more firmly together. The pipes are then removed from the clamps, and the ring of metal and slag that encircles the joint is knocked off, a perfectly clean joint being left. The whole operation takes only a minute or two. In a similar manner the welding of steel rails for railways or tramways can be effected. The demonstration was carried out under the direction of the Allgemeine-Thermit Gesellschaft, of Essen, the owners of the patents, and it is intended forthwith to form a company to work the patents in the United Kingdom.

Views & Reviews.

Theory of Engineering Construction.

This book, we learn from the preface, makes no claim to rank as a text-book, but is a selection of such examples of the questions set in the examinations of the Institution of Civil Engineers which involve a knowledge of useful rules and formulæ, with a short description of their practical application in certain cases; it is intended rather as a brief summary of the various engineering text-books. Blank pages are inserted after each example to enable the reader to add notes if he desires to do so. The book is divided into four sections dealing respectively with theoretical and elementary applied mechanics, theory of structures, strength and elasticity of materials, and geodesy. It will be seen that the book supposes the student preparing for the examinations to already have a knowledge of the ordinary text-books and doubtless of the requirements of the examinations, and yet the author devotes a section to the syllabus of them.

Altogether we see no adequate excuse for its publication: a text-book it is not; as a summary it is inadequate; and as a model of the answers to give in these examinations it is harmful. There are already enough brief summaries published in the pocket-books of formulæ, &c., but we have yet to see a summary that will be clearly intelligible and full, so that it will recall half forgotten things and explain the reasoning on which the rules are based clearly enough to be easily followed. There is considerable need for a new text-book that will be short, clear and yet full of information. This book affords another instance of the style usually adopted in engineering text-books and summaries, namely, in the use of numerous abbreviations, such as V = initial velocity in ft. per second, v = ultimate velocity in feet per second, A = the angular velocity, &c., and in leaving out numerous particles and connective words, and calling each part of the diagrams by letters and not by its name as well. Although this saves space it fails in its intention of clearness, and a little more explanation and the words spelt out would often make it read easily, whereas if the mind has to translate as it goes along and refer to the diagrams at every point, the attention is distracted. The methods, too, adopted of selecting actual examination questions and answering them is not systematic enough for a summary, as often several principles are involved in one answer and thus one has to turn to the index to find any particular item and then ferret it out from the midst of a dissertation on other matters.

"The Theory of Engineering Construction: A Reference Book for Civil Engineers and Students," by Ernest H. Essex, A.M.I.C.E. 5s. nett. London: The St. Bride's Press, Ltd., 24, Bride Lane, Fleet Street, E.C.

NEW BUILDINGS IN BRISTOL.

NEW buildings have just been erected in Wine Street and Union Street, Bristol, on the site of the premises which have been for many years in the possession of Mr. Chambers at the corner of these streets. The area of the ground floor of the new building is occupied by a spacious and well-lighted general drapery shop, on the Wine Street level, entered by two entrances, and also two entrances in Union Street; at the back are archways and a staircase leading to a commodious ladies' hosiery, corset and outfitting department. Beyond this, separated from it by a plate-glass partition, is the gentlemen's hosiery, gloves and general outfitting department, both being accessible from the Union Street entrances. The basement extends over the whole area of the building. The shop is lighted by a covered glass roof at a high level. A staircase extends from the back of the shop; the wall against which it is fixed is constructed with pillars and arches following the lines of the staircase. On the first floor are extensive showrooms. The second floor is occupied by stock rooms, offices and workrooms. On the third floor are dining-rooms, cloakrooms, store-rooms, kitchens, &c. The premises are heated throughout with hot-water pipes, the furnace of which is in the cellar underneath the basement. The artificial light throughout the building is electricity (installed by Messrs. Buchanan & Curwen, under the supervision of Mr. Herbert Thomas Sully, A.I.E.E., electrical engineer). A polished brass and plate-glass shop front, with four deeply recessed entrances, polished mahogany and teak doors and door frames with moulded and carved pediment heads, extends the entire length of the Wine Street and Union Street fronts. The building is designed in the Renaissance style, and the external walls are constructed of brick faced with freestone. The contractor for the building was Mr. R. F. Ridd, of Wilder Street. The carving was executed by Mr. W. Smith, of Montpelier. Messrs. Foster & Wood, of Park Street, Bristol, were the architects of the building.

MODEL DWELLINGS AT PORTSMOUTH.

NEW model dwellings have been erected near Fratton Station for thirty-two families. They are the first blocks of buildings designed on the "flat" system to be erected in Portsmouth for the housing of people who can only afford to pay a small house rent. The erection of the new dwellings has been made necessary through the proposed extension of the town station to include the area lying between it and Station Street, and they are designed to provide equivalent accommodation for the Station Street residents, who will thus be ejected from their present houses. The rent varies from 4s. 6d. to 6s. a week, according to the number of rooms required. The builders and owners are the Joint Railway Companies, and the work of erection has been executed by Mr. Henry Jones, of Southsea, the cost being between £9,000 and £10,000.

The buildings are comprised of two blocks, and each stands in its own tar-paved court, enclosed within a brick boundary wall entered through big iron gates, and a quarter of an acre in extent. One block is composed of two-room "flats," and the second—the one adjoining the station premises—of three-room "flats." Each block is built upon a rectangle, which is bisected into squares. The bisection is caused by stairs and landings that give access to the various domiciles, and the iron railings—about 6ft. high—terminate each landing. Each building is 50ft. high, and consists of four floors, including the ground floor, there being no basement. There are four "flats" on each floor. Access is given from the centre of the building. The stairs and landing are not enclosed, but open to the fresh air. Each floor is of concrete on iron girders, the concrete, for comfort, being covered with ordinary deal boards. Best red local kiln bricks have been used in its construction, and the exterior is faced with Portland stone dressing, with a 4ft. dado of glazed bricks around the base of the building. The "flats" are entered straight into the living room, which is 11ft. by 13½ft., and 8½ft. in height. Around are the usual domestic appurtenances, an iron sink and draining-board is in one corner, with the coal store hidden away beneath it, and on the other side of the room is a handy dresser and a kitchen range. The adjoining bedroom, which is lighted by two windows, is slightly smaller than the living room. In the case of the three-roomed "flat," a second bedroom is placed next to the living room, the two windowed bedroom at the corner of the block being reached by a short corridor. The w.c. is reached from the landing, and one is provided for every two families. The drainage of the blocks is on the best modern lines, and a water reserve is provided by two five hundred gallon tanks placed at the top of each building.

On each landing there is a small trap-door opening into a conduit that runs down the building from top to bottom. Down here will disappear all the dust, ashes, &c., which will be periodically collected from the dust-bin that stands like a water-butt at the outlet pipe below. The approaches and the stairways are lighted by gas provided by the owners, and to ensure cleanliness the walls are faced with "crystopal" glazing lining. With the same object in view, no wall paper will be used in the "flats" themselves, but in its stead the walls will be coated with a patent "water paint."

At the back of each block is a circular dome-shaped wash-house, backed against the boundary wall, fitted, in all, with eight copper "coppers." Around the periphery of the building are draining boards and iron sinks, and the floor, of Bradshaw's asphalt, is to be covered with beech gratings for the convenience of the laundresses,

Surveying and Sanitary Notes.

Mr. George Donaldson, who has been road surveyor to the Middle District Committee of Berwickshire County Council during the past eight years, has been appointed to a similar position under the Kirkcaldy District Committee of the Fifeshire County Council.

A City Improvement.—The London County Council has decided to contribute £16,800 towards the cost of widening Bloomfield Street, where opportunity had occurred owing to the rebuilding of premises. The street has of late years become a main route for the omnibus traffic to Liverpool Street.

A New Pavement is being tried by the Paris municipality. Its inventor is a M. Garcher, who manufactures his product from finely-crushed glass, which is subjected to great heat and heavy pressure, the result being a substance which is said to be less affected by wear than the best and hardest granite, and to support a pressure of over 10,000lb. to the sq. in. To break a slab of the material a weight of nearly five tons falling from a height of 3ft. was necessary. This glass pavement is being laid down at the expense of its inventor in several test places where the traffic is exceptionally heavy. If, at the end of five years, the pavement has worn well, the municipality has undertaken to adopt it on a large scale; if not, M. Garcher, who evidently has confidence in his material, is under contract to replace the old pavement at his own cost. Unfortunately, the new pavement is said to be noisy. It ought not to be dusty, however.

A CONVALESCENT HOME FOR SHEFFIELD.

An important addition has been made to the charitable institutions of Sheffield in the erection and completion of the George Woofindin Convalescent Home, at Whiteley Wood. The late Mr. George Woofindin bequeathed to Sheffield about £120,000, which sum was placed in the hands of trustees, who were empowered, after making certain legacies to existing institutions, to devote one-third of the estate to the erection of almshouses, and two-thirds to building a Convalescent Home. The testator's first wish was carried out in the block of almshouses at Hunter's Bar, opened about a year ago.

The Convalescent Home stands on the hillside at the end of the Whiteley Woods, with a southern aspect, and the whole place is designed so as to obtain the utmost air and light. The front windows command a very pleasant stretch of hill and valley. The hill rises abruptly behind the Home, and wards off the inclement north winds. The grounds are to be laid out with terraces. The building is in the Renaissance style of architecture. It is of red brick with stone dressings, and the woodwork is painted white. The rooms are distributed on a symmetrical plan. The principal apartment on the ground floor is the large dining hall, and here all the inmates will meet for meals. The hall is wainscotted with oak, and the furniture is also of oak. A screen divides the dining hall from the entrance hall. In common with all the rooms, the hall is flooded with light from many lofty windows.

The chief feature of the men's wing—which lies to the west of the central portion—is a large billiard and smoking room, fitted up completely with a full-sized table and inviting lounges. There is also in the wing a reading and writing room, and a parlour. The women's apartments are on the other side of the entrance, and here is a spacious parlour. A verandah runs in front of each wing, whereon the invalids may enjoy the summer air. The women's and the men's quarters have each separate entrances, and separate staircases leading to the sleeping rooms. The matron's sitting-room, the office, and store-room lie to the east of the central entrance, and the kitchen and servants' quarters are placed at the north of the main corridor. The bedrooms on the first floor are arranged on the most approved hygienic methods. The space is divided by slight wooden partitions into cubicles, each room containing two or three beds; the large French windows opening upon a broad balcony. The women's bedrooms are placed above their rooms on the ground floor, and similarly with the men's quarters. Over the central portion on the second floor are rooms which may be used either as men's or women's bedrooms, according as there is an overflow in the number of men or of women seeking admittance. There are also rooms for the isolation of more serious cases requiring individual treatment. The Home will accommodate seventy patients, and is so planned as to admit of extension in the future. The architects are Messrs. Hemsoll & Paterson, of Norfolk Row.

Builders' Notes.

Mr. John Stott, builder, of Marion Street, Bingley, died recently at the age of sixty-five years. Deceased had been largely identified with the extensive building operations of recent years in the Mornington Road district of Bingley.

London County Council.—At last week's meeting the Improvements Committee recommended that £16,800 should be contributed by the Council as one-half of the nett cost of widening Bloomfield Street, City, to 50ft, between East Street and Eldon Street, proposed to be undertaken by the City Corporation. The committee pointed out that the increasing importance of London Wall as a main thoroughfare for traffic had emphasised the necessity of widening portions of it. The recommendation was adopted. Among the Bills against which the Parliamentary Committee recommended the Council to present petitions was that relating to Christ's Hospital. Mr. Stuart Sankey asked what the object was in opposing the Bill. The chairman said that they desired to obtain a *locus standi* before the committee on account of the fact that it was proposed to obtain powers to build over a disused burial-ground. Mr. Stuart Sankey objected to the proposal of the committee as an utterly unworthy one. It was unreasonable to ask the authorities of Christ's Hospital to give up a piece of their land as an open space. To insist upon this would be to do a great harm to a charity which had done an immense amount of good for London. The Council should consider that if the site were not sold the Governors would not be able to proceed with the building of the new school at Horsham, or maintain the school at Hertford. He moved to refer the report back. The amendment was put and lost, and the report agreed to. On the reception of the Bridges Committee's report, Mr. Ward stated that Greenwich Tunnel was now completed two-thirds of the way across the river.

A New Test for Portland Cement.—Mr. J. Patchett, of 3, Lime Villas, Green Lane, Birmingham, forwards us the following particulars of his new test of the condition of Portland cement: Use 10 grains of the cement in question, and empty into 400c.c. of water in an ordinary 500c.c. tubular measure, with 100 markings and about 10 inches between zero and containing mark. Cork or place the palm of the hand over the mouth of the tube, and shake up for a couple of minutes so as to well mix. Twist in fingers to get equal settlement of the cement, and stand by for an hour so as to clarify. Then from a saturated solution of ammonium oxalate pour in up to the 500c.c. mark. At once a white cloud of lime oxalate will form, which allow to settle for a couple of hours and note height above the cement.

The space of	½	mark will equal	½	per cent.	free lime in the cement.
,,	1	,,	1	,,	,,
,,	2	,,	2	,,	,,
,,	3	,,	3	,,	,,
,,	4	,,	4	,,	,,

These percentages are approximate only, and purposely given slightly in favour of the contractor. To cleanse the tube after use, gently disturb the cement with a piece of twisted wire, shake up and throw away. Add in a little hydrochloric acid to free any adhering substance, after which on rinsing with water the tube is again ready for use. A saturated solution of barium chloride will reveal the presence of gypsum in the same way, but in this case half a mark will indicate 1 per cent., while 1 mark will indicate 2 per cent., &c.

Mr. Samuel Emony, of Cobden Street, Dresden, Stoke-on Trent, who until two years ago carried on the business of a builder at premises on Stone Road, Longton, succumbed to senile decay at the age of seventy-one years.

The Phrahzit Fireproof Material Co., Ltd.—An order having been made on March 20th last for the compulsory winding up of this company, the usual meetings of creditors and shareholders were held last week. The chairman reported that the company, which was promoted by the Guarantee and General Trading Corporation, Ltd., was registered on April 15th, 1898, with a nominal capital of £20,000 in shares of £1 each. It was formed to acquire a patent process for the manufacture of a substance known as "Phrahzit," a fireproof material, and with that object to enter into an agreement with Mr. J. T. Szek. Under an agreement of April 14th, 1898, Mr. Szek agreed to sell to a trustee for the company his rights relating to "Phrahzit" for the sum of £13,332, of which £500 was payable in cash and £12,832 in fully-paid shares. The agreement provided that Mr. Szek should be managing director of the company for five years, but, in consequence of his bankruptcy, which occurred in 1898, he was ineligible to act as director, and consequently was appointed manager of the company. The difference between the amount at which Mr. Szek had agreed to sell his patent to the corporation and the amount at which the company were to buy it was £6,665 in shares, and was apparently to be received by the corporation as promoters. Shares to the number of 7,168 were offered for subscription. The first allotment of shares took place on May 17th, 1898, when 420 shares were allotted for cash. The company never had any working capital to enable it to commence business. The company's patent was now held by the liquidator of the corporation, who claimed a lien upon it in respect of advances amounting to £213 made to the company. A statement of affairs had been filed, which showed a deficiency of £7,794 as regarded both creditors and shareholders, but no value had been placed on the patent rights. At both meetings it was resolved that the matter should remain in the hands of the Official Receiver as liquidator, and the shareholders also nominated a committee of inspection.

Keystones.

The New Buildings of the Carnarvon Cottage Hospital were opened recently at a cost of about £4,000.

A New Chapel at Derby.—The New Methodist New Connexion Chapel and Schools in Dairy House Road, Derby, were formally opened recently.

The William Black Lighthouse Memorial on the island of Mull is now completed. The tower is at Duart Point, near Duart Castle. The red and white group-flashing light will be seen for twelve miles out at sea. It is under the care of the Northern Lighthouses Commissioners.

The Bishop Creighton Memorial will take the form of a bronze statue by Mr. Thornycroft in the south choir aisle of St. Paul's Cathedral; a portrait by Mr. Herkomer for the collection at Fulham Palace, from a sketch made by him last year; and, it is to be hoped, a replica for the National Portrait Gallery.

A Memorial Window in the Parish Church of Malpas, near Newport, has been erected to the memory of Captain Freke Lewis Prothero, of the 1st Welsh Regiment, who was mortally wounded at Leeuw Kop on Sunday, April 22nd, 1900, and died at Bloemfontein two days' later. The window depicts St. George, the martyr saint.

A New Board School at Gateshead.—The Gateshead School Board are about to commence Kelvin Grove School, from the design of Mr. J. Landell Nicholson, architect, 55, Northumberland Street, Newcastle-on-Tyne, which was placed first in competition last year but delayed through the bricklayers' strike, which was settled recently. This is the first of two blocks, and gives accommodation for 400 infants on ground floor, and 360 junior boys and girls on first floor, at a cost of about £7,000.

£100,000 for a Church.—Under the will of Lady Charles Brudenell Bruce, a sum of nearly £100,000 is bequeathed to build a church in such part of the country as the trustees may think proper, as a memorial to the testatrix's husband.

A New School at St. Peter's, Rochester, is now being erected. It is situated in Holcombe Road (leading out of Cecil Road), Delce, and is to accommodate 160 infants. The total cost will be £1,850. Mr. G. E. Bond is the architect, and Mr. G. West the builder.

"**The Parish and its Bounds**" is the title of an interesting pamphlet by Messrs. Bernay & Son, architects and surveyors, of 104, George Street, Croydon, which they have just published dealing with the origin of parishes and the ancient custom of perambulating their boundaries, commonly known as "beating the bounds."

The New Chancel of St. Mark's Church, Newtown, was consecrated recently. It contains an organ-chamber and choir stalls, and is of the early geometrical type of architecture, the architects being Messrs. Heaton, Ralph & Heaton of Wigan. It has been built at a cost of £2,900.

Underground Electric Traction.—The joint committee now considering the question of electric traction on the two London underground railway companies are stated to be in favour of the adoption by the Metropolitan of the Gavry system, while the Metropolitan District will be recommended to adopt an American system in use on the elevated lines in New York and Chicago.

A New Jewish Synagogue.—The foundation stone of a new synagogue in Princess Road, Finsbury Park, was laid last week. The new building, which, when completed, will be the northernmost synagogue of the Metropolis, takes the place of temporary premises in Portland Road. When completed it will provide accommodation on the ground floor for 190 gentlemen, and in the galleries for 144 ladies. Mr. Delissa Joseph, F.R.I.B.A., is the architect, and the work of construction is being carried out by Messrs. L. Whitehead & Co. It will be built in red bricks, relieved with stone dressings.

Machen Church has been reopened after restoration. The work, which was carried out under the direction of Mr. C. B. Fowler, F.R.I.B.A., of Cardiff, included the provision of almost new roofs. The old ceiling has been removed, and a wooden ceiling substituted with moulded ribs. The old west gallery was removed, and new pews, pulpit, and desk fixed, whilst a portion of the walls were rebuilt. The plaster has been taken off the interior and exterior walls, and the masonry pointed. The square tower has also been restored, and a new ringing floor provided. During the progress of this work several finds of interest were made. Chief of these were rood-loft steps and entrances, three niches, an old piscina, a west window opening, the remains of a rood screen, and a priest's doorway in the chancel. New ventilating and heating apparatus has been installed.

The Baptist Church House—a project resulting from the Twentieth Century Fund—is now being erected in Furnival Street, Holborn. The Baptist Union finds the need of more room for administrative purposes. The premises will provide accommodation for the Baptist Missionary Society, the Baptist Union denominational meetings, and will serve as a Baptist centre for the entire country. It will occupy part of the site of Kingsgate Street Baptist Chapel, originally erected in 1736, and will have a frontage of 80ft. to Southampton Row when widened as part of the Holborn-to-Strand street improvement of the London County Council. The facade will be in stone, and a clock tower is to surmount its centre. There are to be two blocks, the front block comprising office accommodation, council chamber, committee-rooms, visitors' room, and publication department. At the rear a new Kingsgate Street Chapel will arise, with a Sunday-school beneath, and a large library, the latter also to serve as a meeting-place. The sum of £30,000 has been appropriated out of the Twentieth Century Fund towards the building.

Sunderland Borough Sanatorium.—A new pavilion has been erected at the Sunderland Borough Sanatorium for Infectious Diseases, consisting of two ten-bedded wards and two single-bedded wards. The cost, including furnishing, will be about £5,000. This pavilion will be the fourth, and there is now accommodation for 262 patients, at the rate of 2,000 cub. ft. per patient.

St. Paul's Church, Thornton Heath, is being enlarged by the addition of a new nave and aisles, designed by Mr. R. Philip Day, the diocesan architect, and being built by Messrs. D. Stewart & Sons, of Wallington. The addition will provide accommodation for 700 people, making the full accommodation 1,000. The building is in the Decorated style with open roof and ornamental columns dividing the aisles. It is faced with stone, has Bath stone dressings, and will be roofed with red tiles. The foundation stone, which has just been laid, is in the baptistery, a bay-shaped structure under the west window. The cost is estimated at £6,500.

A New Public Library and Museum at Kilmarnock, to be known as the Dick Institute, was formally opened recently. The building has been erected at Elmbank. The style of architecture adopted is Italian. The front portion is two storeys in height, and the return wings are one storey, the frontage being 138ft. in length, with a total depth of 114ft. The building has fourteen apartments, including a lecture-hall capable of accommodating 500 people. The museum contains the valuable geological collection given to the town by the late Mr. James Thomson, F.G.S., and also a considerable portion of the unique Braidwood collection, left by the late Dr. Hunter-Selkirk. Mr. R. S. Ingram is the architect.

The London and Middlesex Archæological Society paid a visit recently to the churches of Bow and Stepney with the object of studying their architectural and other remaining antiquities. The visitors were received at Bow Church by the rector, who had invited Mr. Hills, the architect from whose designs the restoration work of the church had been carried out, to conduct them over the building. Mr. Hills gave an account of the work, saying that it had been most difficult, in consequence of the soft nature of the stone, which in places had become decayed. Red tiles had been used to mark the division of the old stonework from the new, and the moulding of the latter had been accurately obtained from the mutilated remains of the old building. The old timber roof of the chancel was found to be in an advanced state of decay at the time of the restoration, and great care and expense were necessitated in saving this part of the sacred edifice. The chancel roof was of the same date as the church—the fifteenth century. At Stepney the restoration of the church was far more satisfactory than in the previous case, as the stone was of good quality.

A Sailor's Home at Chatham is now in course of construction on a spacious site near the Drawbridge Road, adjoining St. Mary's National Schools, and close to the Town Hall, Chatham. It is intended to construct a pile of buildings covering an area of 165ft. by 245ft., and including a central hall 100ft. by 48ft., billiard and retiring rooms, and some 600 cubicles. The building now in hand is only a sixth part of the whole scheme. It has a frontage of 88ft. to the Upper Drawbridge Road, and a depth of 50ft. It is set back 50ft from the road, and it will ultimately have a lawn in front and be approached by two carriage drives. The building will be constructed of stock bricks with stone and red brick dressings. It is to be four storeys high, and provision is made in the basement for a spacious kitchen, bath-rooms, pantries, scullery, beer cellar and various stores and offices. On the ground floor there are separate rooms for petty officers and men, with buffet and manager's offices. The first and second floors, overlooking the Drawbridge Road, will contain fifty-two cubicles, each 8ft. by 5ft. 6in. The building is to be heated by hot water. The architect is Mr. G. E. Bond, and the builder Mr. H. E. Phillips, of New Brompton, the contract price being £5,195.

To Subscribers.

Every Subscriber to the "Builders' Journal" is entitled to one of our **Insurance Tickets.** Those who have not yet applied for these should write at once to

The Manager,
"Builders' Journal,"
Effingham House,
Arundel Street.

There are **Three Schemes of Insurance** connected with our Papers, guaranteed by the Ocean Accident and Guarantee Corporation, Ltd. They are of the greatest importance to our Subscribers.

Scheme No. 1 is a free Accident Insurance of **£500.**

Scheme No. 2 is an Accident Insurance of **£500,** giving the following additional advantages:

£250 for Permanent Total Disablement.

£2 10s. 0d. per week for Temporary Total Disablement.

The premium for this Scheme is 1/-

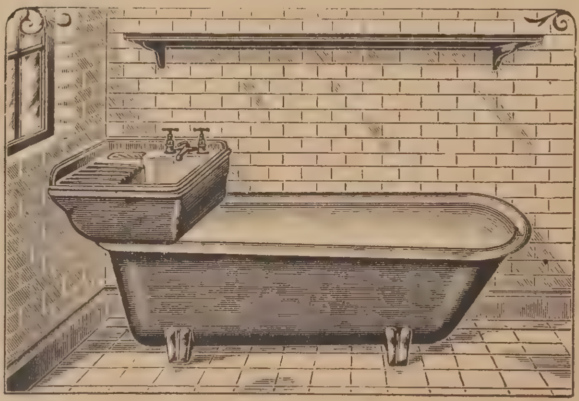
MORRISON & INGRAM'S
. . BATHS. . .



THE PATENT BRAMSTONE COMBINATION BATH & LAVATORY.

The success of the Bramstone combination justifies its introduction, and proves the need for the same.

It is now recognised that no house, however small, should be without bath and lavatory; and since an additional rental is needed of but 2d. per week to yield 5 per cent. on the outlay consequent upon the introduction of the cottage Bramstone Bath, this reform may now be deemed within the reach of all.

It affords economy of space, and a great saving of plumbing is effected.

Only one installation of hot and cold pipes required. It is also made for cold water only. Baths are made 5 ft., 5 ft. 6 in. and 6 ft. long. Prices from £3 11s. 8d. gross.

MAKERS OF ALL KINDS OF BATHS, LAVATORIES, WATER-CLOSETS, URINALS, SINKS, &c., &c.

Effingham House,
Arundel Street,
Strand, W.C.

An Architectural Causerie.

Sculpture at the Royal Academy. It has been stated that of every hundred persons who are "fond of pictures," probably less than twenty take interest in sculpture, and certainly not more than five care anything about architecture. So far as sculpture is concerned, this is perhaps less true now than it was; for with the revival of the sister art of architecture, both in this country and in France, has come a more extended and more intelligent appreciation by the general public, and a greater interest on the part of the entire body of artists Taking the specimens now exhibited at Burlington House as typical of the aims and methods of the bulk of our modern British sculptors, one feature is persistently perdominant, namely, the treatment of pieces of sculpture as isolated works—almost as *objets de vertu*—rather than as forming part of a definite architectural scheme. This view of the art is, of course, a debatable one; but the fact remains that the best sculpture produced in former ages has always been treated as an integral portion of architectural design. Donatello, Ghiberti, Michael Angelo or Luca della Robbia might be cited as examples. Nowadays, however, though the principle still holds good, our sculptors adopt another criterion. It is a common cry –one which we hear regularly at conferences—that the architect, the sculptor, and the painter should collaborate, but it is rarely that such a collaboration is seen in this country, the reason doubtless being attributable to our systems of training, by which each artist, from the very beginning, specialises, instead of first grounding himself in the principles of all the arts and then practising the one for which he feels himself most fitted. In this year's Academy the specimens of sculpture which profess any architectural or decorative treatment can be counted on the fingers of one hand. The most ostentatious is Mr. Onslow Ford's memorial of Queen Victoria, to be erected in Manchester. This shows the great Queen in her robes of state seated on a throne, with the orb in one hand and the sceptre in the other. The background is surmounted by a broken pediment, between the ends of which is a small group representing St. George killing the Dragon. At the reverse side of the memorial stands the figure of a woman holding two babes to her breast, a Corinthian column on either side, and the following words inscribed below: "Let me but bear your love, I'll bear your cares." The whole memorial is displeasing. The great dignity of her late revered Majesty was in voice and manner, not in person, because of her small stature; yet the sculptor, by extending the royal robes at each side, has managed to emphasise this smallness of stature, and the figure is therefore a failure. With regard to the architecture of the memorial, this is sadly lacking in force and skilful treatment; it is a cogent example of what may result from the divorce of the two great sister arts. As pleasing as Mr. Ford's memorial is disappointing is "The Fairy Fountain" (1773), the work of a lady—Miss Rosamond Praeger. This takes the form of a rectangular slab, and is delightfully conceived. In low relief is a little maid who has apparently gone to the well and, tired out, has there fallen asleep, with her head on a stone and a pitcher loosely held in one hand. To the left two joyous elves peer towards the little maid's ear, and typify the course of her dream, while below the stone the water will issue into a small projecting bowl. This fountain is a striking contrast to the somewhat florid effort of Mr. George Simonds entitled "Song and Dance" (1815). Mr. F. E. E. Schenck exhibits two corbels in spandrels (1712 and 1810), the one representing summer—the figure of a woman with corn—and the other representing autumn. Both are well executed. One of the most curious exhibits in the section devoted to sculpture is the portion of the frieze for the marble vestibule at Lloyd's Registry in Fenchurch Street (1791). It is by Mr. F. Lynn Jenkins, and shows ships sailing under a good breeze, with clouds against an iridescent sky, each of the divisions between the panels having the small figure of a woman surrounded by decorative devices. It is the materials used that make this frieze so noticeable. Metal, ivory and mother-of-pearl are combined—metal being used for the ships, the waves and the clouds; mother-of-pearl of different kinds for portions of the waves and for the sky which glimmers between the clouds; and the ivory in the female figures, and here and there throughout the design. It is difficult to form a just conception of the frieze in its present position, but it will doubtless look well when in its proper place. Close to it is a relief of "Dawn" (1787) by Mr. J. Crossland McClure, a most effective piece of work in the manner of that fine sculptor, the late Harry Bates. In the Architectural Room is the bronze canopy for the Dean Colet Memorial to be placed in front of St. Paul's Schools at West Kensington. Here, amid the sculpture, is the group itself (1708), in which Mr. Hamo Thornycroft has been much more happy than in the canopy. The Dean is shown seated on a chair with a book on his lap, while a chorister rests on one knee at each side reading—or about to read—from a book. The statue of Oliver Cromwell, by Mr. Pomeroy (1700), is in the same Central Hall. It is for St. Ives, Hunts., but is not quite so successful as the statue by Mr. Thornycroft which stands so sternly with its back to Westminster Hall (though it may be mentioned that the British Lion on the pedestal, and the pedestal itself, are deplorable). Saverio Sortini exhibits a good design in plaster for a decorated bell (1693), four angels holding up a crown of laurel at the top, and the figure of a praying angel occupying a position on each side of the bell, surmounted, on one side, by a cock crowing, and on the other by a royal eagle. Of the remaining exhibits the majority are busts and statues of eminent men, and emblematical figures, such as Mr. Fehr's "Hesitation" (1697); "The Victory of Peace" (1702), a beautiful female figure by Andrea C. Lucchesi holding a dove to her breast, with the point of the sword in her other hand resting on the ground; "Joyance" (1739), by Mr. Goscombe John; and "The Spirit of Contemplation" (1694), by Albert Toft.

VIEW IN THE ROTUNDA, CITY HALL, NEW YORK CITY. JOHN MCCOMB, ARCHITECT.

It is most difficult to treat the pedestal of a bust successfully. Of the various methods adopted, the most common, and usually the most displeasing, is to cut away the bust in the form of a semicircle and mount it on a small turned pedestal, generally of marble. Mr. Onslow Ford's bust of Sir Frederic Bramwell (1723) is an example of such a treatment. Again, the pedestal may be obscured as much as possible, as in the very fine head of a "Paysan" (1714) by M. Lantéri; or treated as part of the bust, and in the same material, as, for example, the bust of "Doris" (1719) by Miss Gwendolen Williams. Another method is to finish the bust flat and mount it on a pedestal—square or round—larger than the bust itself; Mr. Brock has done this with his bust of Queen Victoria (1820), a very skilful piece of work. Rodin cuts the head out of the top of a block, and leaves the latter in the rough, while still another method was practised in Roman and Renaissance days, that of carving the head at the top of a column or pedestal, and allowing the figure to merge into the latter. It is to be regretted that the least satisfactory treatment is the most common.

In concluding this notice of the sculpture in the Academy we may mention that numerous medallions are shown--though none approach the excellence of French work. A board of bell-pushes and figure-plates (1774) by Mr. Onslow Whiting deserves attention; and those who are advocates for design essentially modern in spirit and subject will doubtless find pleasure in the two figures—straining and struggling—representing "Rugby Football" (1771).

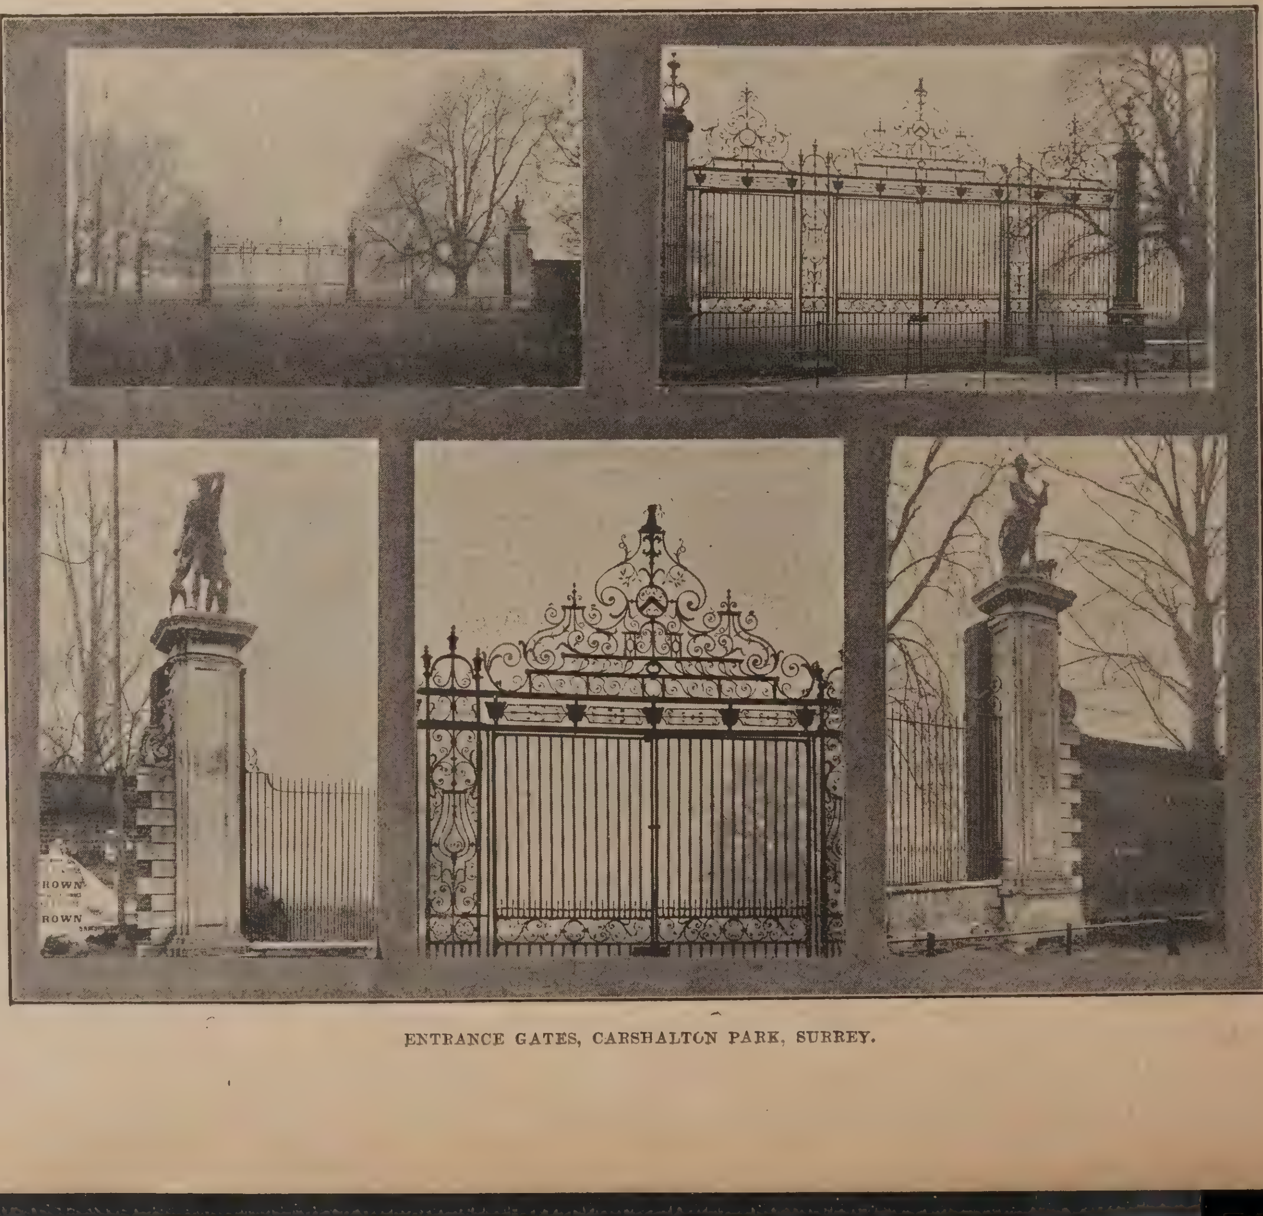
City Hall, New York City. THE view in the Rotunda oi City Hall, New York City, given on the previous page, is taken from "The Georgian Period," a work published by the "American Architect" Company. The City Hall, like the Independence Hall at Philadelphia, and Claymont Court, one of the Virginia houses of the Washington family, belongs to a type which, common enough at the same period in England, is comparatively rare in America. Great city halls presuppose great cities; and there were few towns in New England before Independence which we should reckon greater than an ordinary English village. The Philadelphian State House was among the first, both in time and in size, of a larger kind. New York City Hall was probably designed by John McComb, but a Frenchman in his employ claimed the credit, or some of it. McComb, who survived to the middle of the century just closed, was a warm admirer of Sir William Chambers, and was also influenced by the Brothers Adam. The Hall is of marble and is, "in execution, an advance over earlier buildings in mechanical perfection as well as in monumental design."

York Gate. AT the foot of Buckingham Street, a few paces only from the busy Strand, is a little building which recalls the London of the seventeenth century. Designed by Inigo Jones as a "water-gate" to York House, the residence of the favourite Buckingham, it stood by the water's edge and marked the old bank of the Thames, from which it is now separated by 100 yards, so wide is the strip of land reclaimed by the construction of the Victoria Embankment. Water-gates were numerous then, for the houses of great families lined the southern side of the Strand, and their gardens extended to the river; barges with canopied sterns, manned by rowers in picturesque livery, waited at the stairs, and the side stretch of water was enlivened with sailing craft and small boats. York Gate is one of the earlier works of Inigo Jones after his return from Italy, and a good example of the taste of the day; Italian influence is seen in it throughout. Actually it is a covering for some steps, nothing more; but though small the structure is sufficiently dignified. There is a central arch over a few stone steps, and two smaller ones beside it; all three have very deep keystones. The whole structure is "rusticated" with strong channelling, and "vermiculated," to use two absurd classicisms; the latter, which gives the surface in its present state an appearance of being pitted with holes, is objectionable and meaningless, one of the tricks of the Renaissance. A pediment rises above the centre with Buckingham's arms and coronet; the supporters are outside this, lions holding shields; at the back the Gate appears lower, because approached from higher ground; the keystones of the arches are here smaller and carved with arms and the anchor indicating the Duke of Buckingham's office as Lord High Admiral. Above runs the motto *Fidei coticula crux* (the Cross is the touchstone of faith); over it are four stone balls. Some remains of the second Duke's residence—in which Peter the Great lived for a time—may be seen in the house nearest the Gate, now occupied by the Charity Organisation Society, where there is a stately panelled room on the first floor; the ceiling is finely moulded with roses and apples.

In its present condition the Gate has a forlorn appearance, but it would have been worse but for the London County Council, who purchased it for the public. Not only has the river-bank been moved away, but the level of the ground has risen so that the structure stands ungracefully in a sort of "area." In the first place it should be raised. Then it would be advisable to re-erect it, over some landing place if possible, by the new bank of the Thames, thus restoring it to its original purpose. Even if this were not done, it is absurd to leave it in its present hiding-place. A certain amount of cleaning and repair moreover is absolutely necessary.

ENTRANCE GATES, CARSHALTON PARK.

THESE gates were designed about 1723 by Giacomo Leoni, a Venetian architect, for Thomas Scawen, who inherited the estate from his uncle, Sir William Scawen, a noted London merchant. Leoni also designed the house, but through lack of funds it was never built and only the gates remain to remind us of a man who started to build and did not count the cost. The gates, including the railings, have a frontage of about 100ft., terminating at each end with Portland stone piers 17ft. 6in. high, richly carved, and surmounted by fine lead figures of Actæon and Artemis 7ft. 6in. high. The stone is in a good state of preservation, the panels on the inside being remarkably sharp. These panels have been for some years encased with wood to prevent them being damaged by cattle, and by the vulgar crowd who delight to carve their insignificant names on anything that is old and beautiful. The wrought-iron scroll-work to pediments is very fine, and has been kept in a fair state of preservation. The central pediment is surmounted by the crest of the Scawen family—a hand bearing an uprooted tree. We understand that these gates have been sold for £6,500, and will shortly form the entrance to an American millionaire's park.



ENTRANCE GATES, CARSHALTON PARK, SURREY.

GENERAL VIEW OF ACKWORTH SCHOOL, NEAR PONTEFRACT.

ELECTRIC LIGHTING OF LARGE COUNTRY HOUSES.

PRACTICAL HINTS.

TO any who are thinking of installing electric light in large private houses the following practical hints, dealing with matters that are sometimes overlooked, will doubtless be of use:

(1) In the case of steam-driven plants, arrange for ample boiler capacity. Easy firing is a great factor in saving fuel and prolonging the life of the boiler.

(2) Let the steam engine be so proportioned and its valves so adjusted to the work that when the boiler is at its normal pressure (this is settled by adjusting the safety valve) the engine can only give such power as will drive the dynamo to its full capacity. Overloading the dynamo is then impossible. The same remark applies to both turbines, oil engines and gas engines. With oil and gas engines it must always be remembered that they are most economical when working at their full load.

(3) The battery must be so proportioned to the motive power and to the dynamo that it can be charged at its normal rate only when the generating plant is working at about its maximum power. Overcharging will then be impossible.

(4) In order to avoid unreasonable expense in cable, note that when the power is at a great distance from the house—say one mile or more—it is better to use a very high tension current and drive a motor which would in turn drive a dynamo at the house where the battery would be placed; or, if the power is more than 300yd. to 400yd. distant but less than 1,200yd. to 1,500yd., place the battery at the house and the dynamo where the power is obtained; and when the power is within 300yd. or 400yd. of the house, place the battery in the building where the power is generated.

(5) Do not over-light corridors. This is especially important because as a rule corridor lamps are in use during all the dark hours, and a few of these might easily burn a very large proportion of what was required for the whole house. Whenever possible place the lights where two passages meet so that they can give light to both.

(6) In lighting the living rooms do not group lights together in clusters or fix them close to the ceilings or walls, but place them singly, equi-distant from the walls and from each other, and at a height of from 8ft. to 10ft. from the floor; in halls the height might be up to 15ft. It may be assumed that an ordinary 16 c.p. electric lamp at a height of 10ft. will light 100 sq. ft. of floor surface sufficiently for all ordinary purposes. Where a concentrated light is required for reading or writing, provide a portable hand-lamp connected by means of flexible cord from a wall plug. Such a lamp should have adjustable shades so that the light may be thrown direct on the book whilst it is screened from the eyes.

(7) It may sometimes happen that where the gas fittings in a house have been designed to suit the style of the room in which they are placed, they may be employed as electroliers, but as a rule it is better not to make use of the gas fittings. There is no very great saving, and the effect of a room may easily be spoiled.

(8) In bedrooms much depends on their size, but it is well to remember that dressing-table lights should be directly over the looking glass, and that in almost all cases a second switch from the bed is a luxury that is much appreciated.

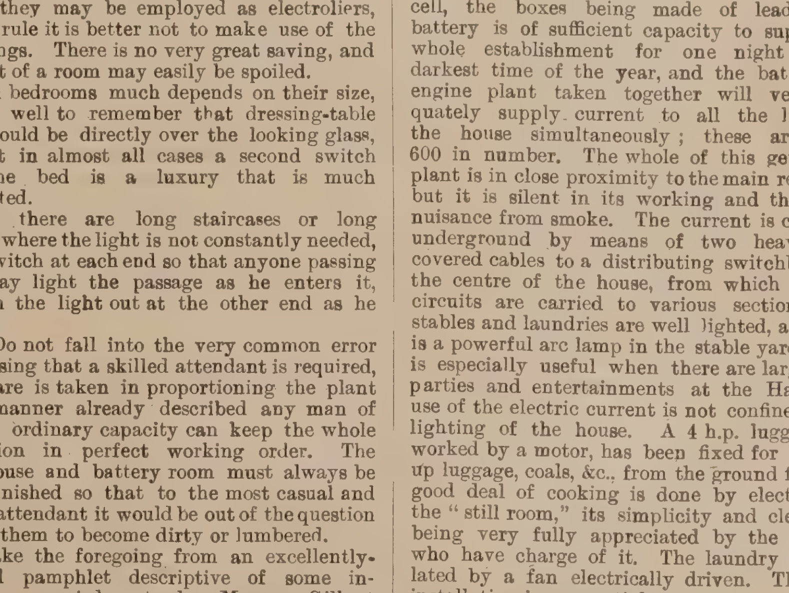
(9) If there are long staircases or long passages where the light is not constantly needed, have a switch at each end so that anyone passing along may light the passage as he enters it, and turn the light out at the other end as he leaves it.

(10) Do not fall into the very common error of supposing that a skilled attendant is required, for if care is taken in proportioning the plant in the manner already described any man of the most ordinary capacity can keep the whole installation in perfect working order. The power house and battery room must always be neatly finished so that to the most casual and careless attendant it would be out of the question to allow them to become dirty or lumbered.

We take the foregoing from an excellently-produced pamphlet descriptive of some installations carried out by Messrs. Gilbert Gilkes & Co., Ltd., Canal Iron Works, Kendal, to whom we are indebted for the accompanying illustrations.

Underley Hall, the residence of Lord and Lady Henry Cavendish Bentinck, is a large and beautifully-situated country house near Kirkby Lonsdale, in the county of Westmorland. It is near the River Lune; but although a good water-power might be obtained from this river during the greater part of the year, there are short periods of drought and flood which, it was deemed, made it unwise to make use of the water-power. The house had been lighted by gas, from its own gas plant, but this had become old-fashioned, and Messrs. Gilbert Gilkes & Co. considered it better to use steam rather than gas as a motive power for the electric light. Two engines, capable of developing 20 h.p. to 25 h.p. each, and suitable boilers, were installed, each engine driving a dynamo having a normal output of 100 ampères at 105 to 140 volts. The switchboard is so arranged that the engines with their dynamos may work together in parallel or separately as occasion requires. A large battery of accumulators, having a capacity of about 1,200 ampère-hours, is placed in a well-lighted and ventilated room on the first floor of the engine-house. There are fifty-four cells, forty-five plates in each cell, the boxes being made of lead. This battery is of sufficient capacity to supply the whole establishment for one night in the darkest time of the year, and the battery and engine plant taken together will very adequately supply current to all the lights in the house simultaneously; these are about 600 in number. The whole of this generating plant is in close proximity to the main residence, but it is silent in its working and there is no nuisance from smoke. The current is conveyed underground by means of two heavy lead-covered cables to a distributing switchboard in the centre of the house, from which separate circuits are carried to various sections. The stables and laundries are well lighted, and there is a powerful arc lamp in the stable yard, which is especially useful when there are large house parties and entertainments at the Hall. The use of the electric current is not confined to the lighting of the house. A 4 h.p. luggage lift, worked by a motor, has been fixed for bringing up luggage, coals, &c., from the ground floor. A good deal of cooking is done by electricity in the "still room," its simplicity and cleanliness being very fully appreciated by the servants who have charge of it. The laundry is ventilated by a fan electrically driven. The whole installation is very satisfactory.

Messrs. Gilbert Gilkes & Co. have also installed the electric light at Ackworth School, near Pontefract, belonging to the Society of Friends. About 300 boys and girls are boarded at this school, and there is a large staff of resident masters and mistresses. Such a community



THE BATTERY-ROOM UNDERLEY HALL, WESTMORLAND.

THE ENGINE-ROOM, UNDERLEY HALL, WESTMORLAND.

necessarily requires extensive premises, and of late years the governing body have been improving the property in many ways, adding a lecture hall, a large suite of masters' and mistresses' rooms and a swimming bath. Approximately, 700 lights are required for lighting, the whole system being worked at 100 volts. There are fifty-six accumulator cells, the battery having a capacity of 720 ampère-hours. The suite of teachers' rooms and the large lecture hall immediately above them are ventilated and warmed by means of air driven through a steam radiator by an electric fan.

Newbiggin Hall, where Messrs. Gilbert Gilkes & Co., also installed the electric light, is one of the oldest houses in Westmorland, and has for generations been the property of the Crackanthorpe family. Many years ago a small mill must have stood about half a mile from the house, where traces were found of the old head-race which brought the water from an adjoining stream to a point at which a fall of about 16ft. could be obtained; but, with the exception of the evidence of the earth-work in this head-race, all trace of the old mill had gone. A weir has been constructed, the head-race reinstated, and a little stone building has been built for a turbine and dynamo, from which the current is carried underground to a building close to the mansion where the energy is stored in a battery of accumulators. In such a house as this some might have hesitated to introduce modern innovations; but Mr. Crackanthorpe has taken so much pains to render the lighting unobtrusive that all the comfort of a good light is obtained without in any way taking from the mediæval effect of this fine old Hall.

NEW DRILL HALL AT HUDDERSFIELD.

GENERAL BULLER opened the new Drill Hall at Huddersfield last week. The building, which has been erected at a cost of about £8,000, has a frontage of about 80ft. to St. Paul's Street, and covers an area of 208ft. by 82ft. It is in three sections, divided by solid walls. In the centre is the main hall 108ft. by 75ft., with a height to the ceiling of 40ft. At each end are balconies stretched across the whole width of the hall. These are 7ft. wide, but as they project at first-floor level, and are not supported by pillars, they do not interfere with the ground floor space available for drilling purposes. The floor area is nearly three times that of the old armoury. On the first floor the principal room, which is 50ft. by 24ft., is utilised as a clothing store, while accommodation is also provided for meetings, examinations, &c., an ambulance store and a room for the use of the signallers. At the east end of the drill hall is a two-storey building, which will practically be devoted to the rank and file. There is a storage room and a well-arranged kitchen in the basement.

ARCHITECTURAL ASSOCIATION.

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

A SPECIAL GENERAL MEETING of the Architectural Association was held on Friday evening last (Mr. W. H. Seth-Smith, president, in the chair) to consider various alterations of the by-laws. A new by-law was approved for the appointment of four trustees in whose names the funds of the Association will be invested; the first are Messrs. G. H. Fellowes Prynne, Arnold Mitchell, G. B. Carvill, and W. H. Seth-Smith. By-law 26 was altered to read, after "treasurer," "*or secretary*"; and by-law 27, after the words "shall be paid by the treasurer," "*or secretary.*" The alteration of by-law 33 was also sanctioned, and now reads: "*The office of president, vice-president or librarian shall not be held by any member for more than two consecutive sessions. The offices of treasurer and hon. secretaries shall not be held by any member for more than five sessions and four sessions respectively.*"

The ordinary general meeting followed, and the following gentlemen were elected members: Messrs. Ernest George, J. M. Brydon, Ralph Berrill, A. E. Chasemore, A. D. Jenkins, J. H. Cooper and James H. Shearer. Mr. Alfred Hands then read his paper on "The Protection of Buildings from Lightning." The following is a summary of it:—

The popular idea of lightning comprises little more than that it is something stored up in a thundercloud which is apt to leave it and travel to the earth, doing damage to objects which obstruct its course; that it is attracted to and conducted by metals; and that when it reaches the earth it disperses or becomes lost, more especially if it gets to water. These ideas give a very incorrect view as to what the problem involved in protection from lightning really is. As a consequence, it is popularly supposed to be a very easy one. All that is thought to be necessary is to have a lightning-conductor raised sufficiently high to attract the lightning; it must be of large size to allow an easy path for the discharge, and its lower end must be taken into moist ground or into water, and there the matter ends. This view also contains an element of truth, but it is very far from being the solution of the problem. Instead of being a simple matter, protection from lightning is a most complex subject.

I cannot, within the narrow limits of a paper, place before you the whole subject, but I hope to be able to show something of the principles which are involved, and more especially as to the common-sense view; for, although it is very often ignored, there is such an aspect. I think that little could be said in favour of lightning conductors if they would not bear the searching light of common sense. It is not a subject which can be taken up lightly and disposed of in a few words, and a thorough knowledge can only be obtained by very close study, exhaustive experiments, a careful investigation of the phenomena exhibited by nature when objects are damaged by lightning, and a very extensive experience of the questions to be considered in the protection of buildings.

It is impossible to arrive at the amount of damage to property due to lightning, which occurs yearly in this country, but I believe I am below rather than above the actual figures in saying that it must be between £50,000 and £100,000. I have for many years been collecting particulars of damage of this nature, from which I am at present preparing a map of England showing the positions and nature of the objects struck. This work takes considerable time if one desires to be accurate, and I have at present only completed from the beginning of 1898 to the present time. Most of our large towns, and particularly the manufacturing ones, are indicated by the number of cases of damage; I think this ought to dispose of the mistaken idea sometimes expressed that the smoke in towns acts as a protection.

In order to understand the principles involved in the science of protection, it is necessary to clearly understand the electrical action in a storm of this kind. You are aware, of course, that lightning is merely electricity differing in no respect from that generated by a frictional or influence electrical machine, except that it is on a gigantic scale. You are also doubtless aware that this form of electricity called static is of a dual nature, generally called positive and negative; that it is impossible to produce one without the other, and that by a process called induction, where the one state is existent the other will be near it, being only prevented from joining by whatever insulating material is interposed. The existence of one electrical state is proof of the existence of the other, and that it is as near as the insulating material will allow it to get. This is precisely what occurs in a thunderstorm. The storm clouds provide the charge of one nature, and the earth with the buildings and other objects on it has by induction the other—the air between is the insulator which tends to prevent their joining. Of course, it frequently happens that different clouds in one storm are oppositely electrified, and hence we get flashes from one cloud to another, but as these discharges do not affect our safety, we may leave them out of account. Presuming that the cloud is positive, the earth and the objects on it are necessarily negative, and therefore there is a state of tension between the two which becomes more acute as the respective charges increase, until at last the tension becomes too great, the insulating material gives way, and momentarily the path of the strain becomes visible by a line of matter rendered incandescent, and this we call lightning. The strain has existed before the flash appears, and the path it follows is all prearranged. One cannot say that anything has left the cloud to come to earth, any more than that something has left the earth to travel skywards. It is merely the re-uniting of the two states, or rather the restoring of the equilibrium which had before been disturbed. Wherever a difference of potential exists there is a strain due to the necessity of restoring the equilibrium or level, and if the strain is great enough to break down the insulating material, a spark will pass. Therefore, if we could do away with the strain, or reduce it in time, we should prevent the breakdown, or in other words prevent the discharge taking place, and this is what we endeavour to do when we provide a lightning-conductor with points. They possess this power; they may almost be considered as safety-valves. While the potential in the clouds is being raised in the process of the formation of the storm, every point is reducing the strain by what is called brush or silent discharge. Theoretically, a lightning-conductor should never be struck by lightning; practically, it may be because the potential may be raised so rapidly that the points cannot reduce the strain quickly enough. Points, however, possess a very considerable protective effect and form a most important function of a lightning-conductor, although not absolute. The conductor might even be so far inefficient that it would not convey a lightning discharge harmlessly and yet the points would still exert their protective effect in this way. During a thunderstorm the points of a conductor may frequently be seen to glow with the light of the brush discharge, and this may even be concentrated into short sparks or a spitting effect, as Professor Lodge graphically put it. Then we hear people say they have seen the lightning playing about the lightning-conductors. When this occurs the tension must be enormous, and it is just a question whether the lightning flash will occur or not.

If the points are not able to prevent discharge, the second function of the lightning-conductor, its power of conduction, should prevent any harm occurring to the building on which it is fixed if it has been applied on scientific principles, but it is just in this that the complicated and difficult nature of the matter consists.

When, in 1752, Benjamin Franklin established the identity of electricity and lightning, he immediately suggested the possibility of preventing the damage which this force caused to buildings. Buildings in Franklin's day were easy to protect; those of to-day are very different. The next important epoch was when William Snow Harris became interested in the subject, more especially as regards the protection of ships from damage by lightning, the losses sustained from this cause both by the Royal Navy and the mercantile marine being at that time very considerable. Snow Harris succeeded in getting his system of protection adopted by the Admiralty, and became the premier authority of his day on this subject, ultimately receiving the honour of knighthood for the services he had rendered. Many of our important public buildings were protected in accordance with the plans and specifications of this distinguished scientist, and no case of failure occurred to show that he had blundered. I have had the opportunity of examining some of the buildings fitted in accordance with the plans of Sir William Snow Harris, and have been particularly struck with the thoroughness with which they had evidently been studied. Snow Harris advocated copper as being the best conducting and most durable metal, and therefore the most suitable for lightning conductors. His system, which generally comprised a number of conductors on one building, was to connect all the metals about the structure to one another and to the conductor system so as to bring the whole mass into a state of uninterrupted conduction. A most interesting controversy took place between Mr. C. V. Walker, F.R.S., who was at one time President of the Meteorological Society, and Sir William Snow Harris on the question of side-flash or lateral discharge. Walker contended that sparks might pass between a lightning conductor and other metals about the building adjacent to it. Snow Harris made a distinction between metals which were earth-connected, and would therefore form alternative paths for the discharge, and insulated metals which would not assist its passage to earth. He argued that while there would be a division of the discharge between the conductor and the alternative path, sparking to the insulated metals was impossible. One wonders, in reading his works, whether he really believed that sparks would only occur to metals leading to earth. The elaborate precautions that were taken to connect his conductors with all the metals about the building, whether going to earth or not, do not bear out this contention, or where would have been the necessity for such connections? The only construction I can put upon the matter is that he meant that with his system of protection side flash was impossible. I acknowledge that this argument savours of special pleading for Snow Harris, for his writing seem to indicate that his words are to be taken literally. He says, "Can the bodies *a*, *b*, *c* elicit from the conductor, at the instant of its transmitting a heavy discharge of lightning, a destructive lateral explosion upon the parts of the building on which they happen to be placed?" This is the legitimate and fair definition of lateral discharge as applicable to a lightning rod. I have no hesitation in saying that if that conductor was struck by a heavy discharge of lightning, as he calls it, sparks would pass, though they would be merely sparks between the conductor and those metals, not "explosions" in the bricks to which they are fixed, and there would probably be no traces afterwards of their passage; but if we altered the conditions slightly by placing the conductor about 3in. from the corner of a building, and the metals 3in. round the corner, the bricks between would be slightly damaged.

The next event to which I have to draw your attention is the formation of the Lightning Rod Conference. In 1878 the Royal Meteorological Society decided that it was expedient that a conference should be held to consider the best means of protection from lightning, and issued invitations to certain other learned societies to appoint delegates. Their labours extended to December, 1881, when their report was issued. During that time they had exhaustively examined all the evidence they could collect as regards damage by lightning, the methods adopted by manufacturers, and the writings of British and foreign authors. The report of the Lightning Rod Conference, as it is called, was published by Spons in 1882, and became the standard work of reference on the subject in the English language. Personally, I consider the rules they drew up, although not faultless, are admirable in the way in which I believe they were intended—that is, as a guide to architects and others interested in buildings, which should enable them to learn something of the methods employed in the protection of such structures, and give them some such knowledge as should enable them to see that the work was being carried out on scientific principles; to do away with prejudices often entertained against the use of conductors; but most of all to try and dispel the extraordinary ignorance displayed at that time by some of those engaged in the erection of conductors. I cannot believe that the report was ever intended to serve as a complete guide capable of rendering any one who read it an expert fully qualified to plan the lightning conductor system necessary for the protection of a building. If it was, it was a dismal failure, and I do not believe that it is within the power of any man, or of any body of men, no matter what their scientific attainments, to formulate a set of rules which shall serve such a purpose. Nothing is said in the report about sparking, or side flash, from the conductor in actual words, but they drew attention to the necessity of connecting all masses of metal about the building with the conductor. As in our criticism of Snow Harris, we can say, if sparking, or side flash, was not admitted, where would be the object of advising these connections? This rule commences: "As far as practical, it is desirable that the conductor be connected to extensive masses of metal, such as hot water pipes, &c., both internally and externally." I consider the wording of this rule most unfortunate, because practicability has nothing to do with the matter. The connections are either necessary or they are not. If they are necessary, practicability must not be taken into account; means must be taken to connect them even if it is inconvenient. This rule has led to the assumption that these connections are not of vital importance, and therefore they are not generally made. With internal metals, for instance, it is rarely considered practical to connect them, because people naturally object to have their walls cut about in order to have a connection carried through. The explanation of the anomaly is, to my mind, to be found in the words which follow: "But it should be kept away from all soft metal pipes, and from internal gas pipes of every kind." Obviously, if connecting to internal metals is not practical, the alternative is to keep the conductor sufficiently far away, but the point is generally missed. Probably the vagueness of the first part has led architects and others to think that the whole rule is unimportant, for in the course of a rather wide experience I have never yet met an architect who took into consideration the positions of inside gas or water pipes or other metals when deciding where he would have his conductors fixed.

The conference clearly stated that lightning conductors may be of iron or copper, but advocated the latter metal as being more convenient and durable, and in the end the cheapest. They stated that the minimum size to be used should be a weight of 6oz. to the foot run, which in copper tape, the form now mostly used, would be ¾in. wide by ⅛in. thick.

The last epoch that we have to consider brings us to more recent times. In 1888, Dr. Oliver Lodge, F.R.S., was invited by the Society of Arts to deliver two lectures on "Lightning Conductors" in memory of the late Dr. Mann, at one time a President of the Royal Meteorological Society, and who, during his lifetime, had taken a keen interest in the subject of protection from lightning. Professor Lodge is one of our most brilliant scientists, but I do not know that he had paid particular attention to this subject previous to this invitation. Professor Lodge delivered these lectures, and I am speaking mildly in saying that they created a sensation. In the course of these he carried out experiments intended to show that a very thin iron conductor was better for the purpose of a lightning conductor than a thick copper one. Incidentally he showed that small-size iron wire was better than stout iron, and that small size copper was better than stout copper. Here we have what appears to be a paradox—the worse the conductor the better it is. It is

THE DINING-ROOM, UNDERLEY HALL, WESTMORLAND.

necessary to say that Professor Lodge states that "the values given are a record of a definite experiment, but their precise value depends on the circumstance of the experiment. It is easy to arrange so that the iron is less effective than the copper." Nevertheless, he remarked that he looked upon copper conductors as doomed. Professor Lodge then read a paper before the Institute of Electrical Engineers, in 1889, at which most of the leaders of the electrical world were present. In this paper Dr. Lodge discussed at great length the question of side flash, or sparking, from a conductor, but he did not draw a line, as Snow Harris had done, between sparking to insulated metals and the dividing of a discharge between a conductor and an alternative path. On the contrary, he appeared rather to treat all side flashes as being portions of the discharge, leaving the conductor to go to earth by other and sometimes worse routes, with the exception of secondary effects or the sparkings caused by induction in metals not connected with the conductor. He contended that the older electricians, as he termed what may be called the votaries of experience, had not taken certain laws and effects into consideration. One of the main points in his arguments was that a lightning flash is not a single discharge, but is oscillatory; that is to say, that it consists of a number of discharges backwards and forwards till it comes to rest, a dozen or more alternations probably occurring in a flash occupying a minute fraction of a second, and that under these circumstances the generally accepted ideas as to the comparative conducting value of copper and iron are changed. Therefore, he now contended, iron of the same thickness as copper was "a trifle better, certainly not a whit worse than the latter metal." In the discussion which followed, which extended over three meetings, Dr. Lodge was opposed by the majority of the speakers. They did not, however, protest against the possibility of side flash, but the ground mainly taken up was that lightning was not oscillatory, and they contended that the older views as to conductivity were sound. The question is, I consider, an unimportant one, because if harm was not caused by the first or second swing, the remainder would be harmless.

Dr. Lodge illustrated his lectures and paper by some most interesting experiments, which, however, I consider were not conclusive, because the conditions were not such as occur in Nature. To this day I often hear it said that Dr. Lodge says lightning conductors are useless, and therefore I may quote his disclaimer. In his book on "Lightning Conductors," published by Whittaker's, he said: "I may be permitted here to repudiate the doctrine which has several times been attributed to me since the Bath meeting—that it is safest to be without lightning conductors altogether. The long experience of persons learned in this art is by no means to be despised, and until an agreement as to improvements has been arrived at, the safest plan for ordinary persons is to adhere to existing practice."

Dr. Lodge's work forms, in my opinion, an important addition to the literature of the subject, if taken as purely of theoretical value, and on which we must base our own ideas of the practical results which are to follow. He has called attention to the necessity for taking certain effects more fully into consideration when arranging our system of defence, and has shown us some of the scientific reasons for their appearance, and for this we owe him a debt of gratitude such as we owe to every man who labours to give us a clearer insight into the mysteries of Nature.

The effect so far of his work, however, appears to me to have been to cause a great deal of confusion in the minds of some people, and I must protest against the exaggerated views that are often expressed in relation to these effects. For instance, Dr. Lodge has referred to side flash and to the surging effect of a discharge, and other writers have referred to these effects as if they were some new invention of the devil tacked on to lightning to render it still more deadly than of old. These effects have existed since the days when lightning conductors were first invented, and even before then to the earliest times in which metals used in the construction of buildings hace acted as accidental or partial conductors of the electricity from thunderstorms.

Dr. Lodge has made suggestions as to improvements which he considered might be made in the applications of lightning conductors. He prefaced these by saying, "It is a matter on which I have not the slightest wish to be dogmatic; and if I make a few apparently definite assertions, it is only by way of expressing such judgment as I have been able to form at present, and they are to be taken as intended more by way of suggestion and question than anything else." Leaving out of account those rules which apply only to powder magazines and lightning arresters, and three which refer to testing and which are not of practical value, there are only ten which differ materially from previous scientific knowledge of the subject. I will give these ten rules, together with a few remarks, though my later observations will deal more fully with the matter :—

(1) The use of copper for lightning conductors is a needless extravagance.

(2) Iron has advantages over every other metal.

My later remarks will deal with the question of copper *v.* iron.

(3) It is hopeless to pretend to make the lightning conductor so much the easiest path that all the others are protected. All possible paths will share the discharge between them, and a lot of apparently impossible ones.

This rule does not differ, except as regards the "apparently impossible ones," from the dividing of a discharge among alternative paths Snow Harris explained about fifty years before. My later remarks may explain this more fully.

(4) At all places where water and gas-pipes come near each other, and in general where one metal ramification approaches another, it is best to connect them metallically.

This rule Dr. Lodge has since admitted is very open to criticism, but I consider that it would be an admirable one if it was only qualified by being made to read that in some cases it may be absolutely necessary to make such connections.

(5) It is not wise to erect very tall pointed rods above the roof of a building.

(6) In ordinary houses it may be well to try and insulate the lightning conductor from the walls, so as to lessen the chance of side flash to metal stoves and things inside.

(7) In chimneys it may be well to use insulators to protect the bricks from concussion.

These three rules Dr. Lodge has since described as very doubtful.

(8) The orthodox rule "Connect all pieces of metal to the lightning conductor" requires modification thus, "Connect all pieces of metal to each other and to the earth, but not to the lightning conductor."

(9) It may be always reckoned safe to earth things independently. It is often not safe to connect them to the lightning conductor; *e.g.*, an inside lining of a chimney should be well earthed, but should not be used as lightning conductor, nor connected with it. The same with rain-water pipes and gutters. The same also probably with lead roofs.

After each of these two rules Dr. Lodge places a note of interrogation to show, I presume, that he was doubtful about them, and he has since admitted the force of the criticism to which they were subjected, and says he gladly takes refuge in another rule which contains the truism that the most difficult thing is to know what to connect and what to avoid. These two rules would be of vital importance, and would revolutionise present practice if they could be justified, but I hope to show you that they would be dangerous in the extreme, and far, from tending to increased efficiency of conductors, would cause failure. They have, however, been quoted by others as if they were correct, and without Dr. Lodge's subsequent remarks, or even the notes of interrogation after them.

(10) Over the top of tall chimneys it is well to take a loop or arch of the lightning conductor made of any stout and durable metal. Dr. Lodge has since modified this rule, but I need only say that the coronal band with points at intervals, recommended by the Lightning Rod Conference, answers the purpose perfectly.

Although Dr. Lodge's views did not, I think, obtain the consideration they deserved, we may still consider that there are in existence the two schools, the one of theory pure and simple, as represented by Dr. Lodge, and the school of experience, as represented by the teachings of the older electricians, as Dr. Lodge called them. Between these two we must discriminate and formulate the method of procedure which will ensure success. Theory and experience are each in their way of the greatest value, but one is useless without the other. For the sake of distinction, however, we will keep to the terms "theory and experience" in considering the points in dispute. Experience says, let your conductors be of copper, which is of better conducting capacity than iron or any other metal which it would be practical to use for the purpose; and besides, it is the most durable, and in the end the cheapest. The comparative conductivity of copper and iron they base on tests made by many distinguished scientists, both British and foreign, who have shown that in the case of steady currents of electricity copper conducts about seven times as well as iron. Theory says that for sudden discharges such as lightning the conditions are changed, and that iron is "a trifle better, certainly not a whit worse than copper," and that the use of the latter metal is a needless extravagance. Also that instead of having single conductors of copper, a number of lines of conduction of iron wire of small size is better (ordinary telegraph wire is suggested) that these wires should be carried down each corner of every chimney stack on all sides of the building. On purely theoretical grounds I see little to choose between the two systems, provided the conductors are applied on scientific principles. A man who understood the subject thoroughly would be able to protect a building as perfectly with one system as with the other, but the many iron wires would be more difficult to apply successfully, because it is easier to place one or two conductors so as not to be within sparking distance of metals to which it is not advisable to connect them than to fix a dozen so. I have only had an opportunity of examining one system of the theory-sort erected in this country. So far as I know it has never been subjected to the test of lightning, but it is, nevertheless, an instructive case. A chimney shaft was about to be built at the time of Dr. Lodge's lectures, and the engineer in charge, who was an electrician, had followed Dr. Lodge's arguments very closely, and decided to try the small iron-wire system. He therefore had eight galvanised iron wires fixed vertically, one at each angle of the octagon and running round the shafts at intervals. Not having, however, implicit confidence in this type, he also had an ordinary conductor of copper tape fixed to the same shaft. The cost of the iron arrangement was about £35 to £38, that of the copper one £22. When I examined the two systems after a lapse of about eight years I found the iron wires at the top of the shaft completely eaten away. The copper conductor was practically as good as when it was erected. This would, I think, be a fair sample of the theory type of conductor—durability sacrificed and original cost increased tremendously. For it is a very great mistake for Dr. Lodge to suppose that his suggested iron telegraph wire system would be cheaper than the copper tape generally used. Iron is, of course, cheaper than copper, but the cost of fixing is a serious item, and where say several hundred feet of iron wire has to be fixed in place of a hundred feet of copper tape, the total cost must be greatly increased if the work is to be done by competent men under the guidance of an expert.

Personally I do not attach very great importance to the kind of metal to be used for a lightning conductor. The conductor may be of copper or iron, or it might even be of lead; so long as it is of sufficient capacity not to be melted by the heating effect of a severe discharge it will answer if properly applied. On the score of durability and cheapness, I have no hesitation in saying that the older type, or copper tape conductor, cannot be beaten. On the score of appearance, too, copper tape has the advantage, and appearance has to be considered, for I do not think there are many architects who would consent to have their work turned into what would look like enormous birdcages.

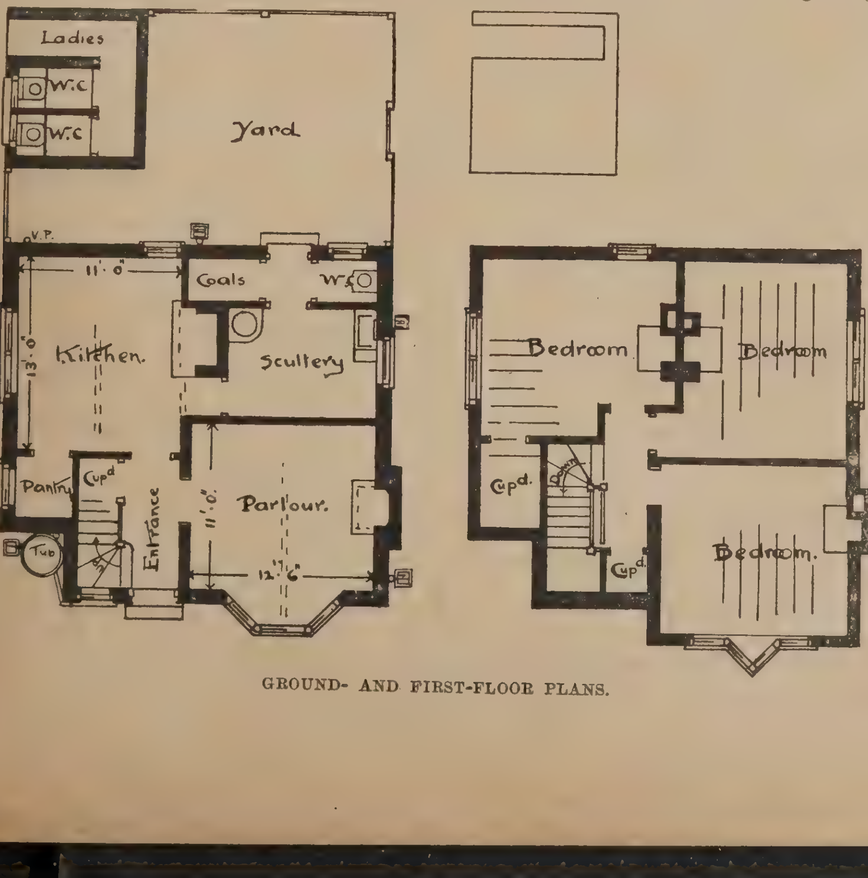
As Dr. Lodge has himself said, it is impossible to make the lightning-conductor such a superlatively easy path that the discharge will take that one only if other paths are open for it, but it is here that the skill and scientific knowledge of the expert has to be shown. If one had to protect a structure composed only of brick, stone or wood, and with not a particle of metal in its construction, nothing would be easier. All that would be necessary would be to have a conductor of metal, pointed at the top and leading down into the earth. It might be made in lengths scarcely touching one another, and the earth connection might be absolutely bad, and yet the building would be protected. All that would happen would be heating and possible fusion at the joints, and the ground at the foot of the conductor might be blown up. It is very rarely, however, that one is called upon to protect a structure of that kind. Modern buildings are often a mass of what I may call unintentional lightning-conductors, for all the metals used in the construction of buildings are conductors of electricity, and therefore conductors of lightning. Some of these metals have good earth connections—in fact, gas and water supply-pipes have excellent "earths," owing to the extent of their ramifications underground; and it is a matter of considerable difficulty—in fact, in some cases practically impossible—to make the "earth" of the intended conductor as good as these accidental ones unless we actually connect the conductor to the underground mains. This is the common-sense view of the matter. If you fixed one conductor to the highest part of a building, and another one, say, 6ft. up the wall, and approaching within a foot or two of it at that point, and both with equally good earth connections, I do not suppose you would be surprised if the lightning divided and part went down one conductor and part down the other, or, if brickwork intervening, a hole was made through it. Why, therefore, should you be surprised if, when arranging for your lightning conductor, you take no heed of the metal inside the building, and place one conductor down outside, and another one in the form of a gas-pipe inside, and the discharge divides between the two, knocks a hole in the wall, and sets light to the gas? Lightning has to follow certain unalterable laws, and one of those laws is that if two or more paths are provided, it must divide between them. Out of the many cases of true failure of lightning conductors that I have examined I have found that 90 per cent. have been due to neglect of this common-sense view, as I call it. We should arrange so that the division shall not take place. We cannot prevent a building being attacked by lightning—any structure, from a cathedral to a hencoop, may be struck. All we can do in this respect is to provide our conductor with points (and the more the better) to lessen the liability of its being struck. We can, however, go further than this. We can, by carefully studying our building, both inside and out, arrange our conductor system so that the lightning shall go harmlessly past it through our conductor and leave our building and its contents secure. A distinction should be drawn, as Snow Harris did, between side flash to other paths and sparking to metals which do not afford an alternative path, though not agreeing with him as to the impossibility of the latter.

LODGE, WEST PARK, HULL. JOSEPH H. HIRST, Architect.

When the conditions are proceeding which lead to a discharge of lightning occurring, induction, as I have already pointed out, takes place; that is to say, there is an enormous difference of potential between the cloud and the building about to be struck; this inductive action is stronger in conducting than in non-conducting masses, therefore the lightning conductor and other metals would show this action better than brickwork. If the metal is connected to earth the action would be quick; if the metal is insulated the action would be slower, because the charge would have to filter through the insulating material gradually. Local sparking is not as a rule a very serious matter. A small hole may be made through brickwork or other intervening non-conducting matter, but that is about all, unless some inflammable material intervened, when a fire might be caused.

Now we come to the question of division of a discharge between a lightning conductor and other paths to earth, which form what I call accidental conductors. Given a lightning conductor outside and a gas or water-supply pipe near to it inside the building, and this is a very different matter. The action as regards difference of potential and consequent strain and resulting spark is somewhat similar; but the sparking distance is very much longer, and the spark more powerful, because it is actually a portion of the lightning discharge passing. If we knew the respective inductive resistances of the intended and accidental conductors, we could gauge approximately what proportion of the discharge would go to earth by the former and how much by the latter. But even if you got nineteen-twentieths of the discharge through the former and one-twentieth through the latter, it might be a serious matter. I may here refer again to Dr. Lodge's suggestion that metals should be connected to earth and not to the conductor.

As to the methods for rendering our system of protection perfect. We must first of all decide on which are the parts of the building liable to be struck by lightning, and protect them either by separate conductors or by branch conductors carried to one or more mains to earth as may be necessary, and we must see that these conductors afford as little resistance as possible. The joints must be soldered so that they will not only be perfect at the time they are put up, but will remain perfect. The earth connection must also be made so that this path is at least as good a one as other paths about the building; and besides this we must carefully study our building, both inside and out. We must take into consideration all the metals used in its construction, both as regards their relation to the conductor system and to one another, and take such precautions that neither division of the discharge shall occur unless we intend it to occur, nor sparking in places where sparking would do harm. It is here that the skill and experience of the expert have to be displayed, and I cannot give you any rules for your guidance on this matter, for buildings differ so much in their construction and arrangement that rules applicable to one case would be absolutely useless for another. Nothing is of use but knowledge and experience, and, as I have already indicated, these cannot be imparted or acquired in a short space of time. I can only say that in some cases connections are made and in others the dangerous metals are avoided, but that great discrimination is required as to what metals are connected and what avoided. Sometimes dividing the discharge between several paths or over a wide extent is the best plan, and sometimes other plans are adopted according to the exigencies of the case or the particular combination of dangers which one may find to exist.



GROUND- AND FIRST-FLOOR PLANS.

I may, in conclusion, discuss a matter which is of great importance to architects, and that is as to what parts of a building are liable to be struck, and which therefore require protection. I have devoted many years to this question, and have examined many thousands of buildings which have been struck, first, with the object of formulating a theory, and afterwards to prove that theory; and I propose putting this before you as briefly as possible. The main principles are simple, and possibly it is the very simplicity of the matter which has led to its being overlooked. The popular idea is that it is the highest point of a building which is struck, but probably some of you may have met with cases in which others very much lower down have been damaged. I have come across hundreds such. The explanation is that the nearest part of the building to what I may call the point in the cloud from which the discharge originates gets struck, and the highest is not necessarily the nearest. A discharge occurs between two planes or points, one of which is in the clouds and the other is in the ground; the building is merely an object *en route*, as one might say, which forms a path of less resistance than the surrounding air. Now, a lightning-conductor does not attract lightning except inasmuch as, being of metal, induction and consequent difference of potential takes place more strongly in it than in the surrounding non-conducting materials, and in this respect the thin line which is intended to protect the building from lightning is insignificant compared to the other metals used in its construction.

Brickwork, although non-conducting to a certain extent, offers a lower resistance than air. Therefore it would be contrary to science for a discharge to pass over a chimney-stack or gable-end to strike a lightning conductor merely because it is metal, when probably the gable-end or chimney has a much larger extent of metal just below it. Even if the lightning-conductor affords the best path to earth, the path of least resistance would be through the gable-end or chimney and the house to the conductor, rather than through a corresponding distance of air, to get to the top of the conductor. We have to consider two kinds of discharge, one the most dangerous type, which occurs fairly straight through the air in an almost vertical line, and the less dangerous flashes which occur in a somewhat oblique line, and are generally meandering in their course. These latter flashes are often called forked lightning, though this is a misnomer, and are popularly, but mistakenly, supposed to be the most dangerous. It is the straighter flashes which do the most harm; those which are capable of breaking almost straight through the air without having to go out of their course to take advantage of any little conducting matter, such as moisture, which will assist them on the way. The meandering flashes are not by any means to be ignored; it is only in comparison with the straighter ones that they are mild.

In arranging what parts of a building require protection, we have to consider the various points in the sky from which the discharge may originate, and so arrange our system that the conductor, or one of its branches, will form the nearest part, no matter from what direction the discharge may come. There is, of course, a limit to the angle of obliquity, and this limit should be about 40 degs., and my observations have led me to infer that the greater the angle of obliquity the milder the discharge. We hear reports sometimes of buildings having been struck by lightning in absolutely unaccountable places, such as lightning missing a tall spire and striking the nave close underneath it, or even striking through a window. Like all other so-called vagaries, freaks, or perversity of lightning, such peculiarities do not exist except in the minds of people who do not understand the matter. Lightning is a force of Nature, and, like all other natural forces, is governed and regulated by laws more unchangeable than those of the Medes and Persians; therefore, if we find cases which do not quite agree with our preconceived ideas, we must admit that we either do not know the law, or that we have overlooked some important factor of the case, and not put it down to a sudden and capricious change in the laws of Nature.

In arranging as to which parts to protect, we can consider this question as to which would be the nearest parts, and we can take it that these are parts which might be struck; other parts higher than these may be absolutely safe if they come well within a line drawn from one to the other, provided other circumstances are equal; but they may not be, for metals either inside or outside the building, and other circumstances, may complicate the question so far that this rule does not entirely apply. Notwithstanding all the difficulties that I have pointed out, absolute protection is possible if the building is thoroughly studied. We can either protect it so that we can say not a brick or stone shall be disturbed, or we may say we will protect it so that the inmates shall be safe and the building shall not be set on fire or damaged to any extent —we may say that a stone finial at this end may be knocked down, or a few bricks or tiles disturbed there, and that we will risk that, as we do not consider this damage worth providing against; but if we do this we must realise that we are running the risk, and if the stone finial is thrown down, or the bricks or tiles displaced, we must consider that we deliberately took the risk, and that it is not a failure of our system of protection.

In conclusion, I can only advise you not to make the general error of providing your conductors of exceptionally large size under the mistaken idea that by providing your conducting path of exceptional capacity, as it is wrongly called, you can ignore the scientific aspect of the question, for no increase in size of the conductor will compensate for this.

A letter was read from Mr. Killingworth Hedges, M.I.C.E., stating that he had read Mr. Hands's paper and agreed with him that the longer the subject was studied the more difficult it seemed. Mr. Hands had mentioned the advantages of having many points, but then went on to say that "they may not be able to prevent discharge"; this inability was, in his own opinion, only a question of their number; as usually installed without regard to intercommunication some might be inefficient, but on a properly protected building the number of points should be so distributed that the whole building was bristling with the so-called negative discharge, and therefore the actual disruptive effect was warded off. He had endeavoured to carry this out in the protection of Saint Paul's Cathedral, where there were over 100 points all connected with one another and at intervals to the earth. So convinced was he that this was the correct system that in the work now being installed under his supervision at Westminster Abbey the actual number of points in proportion to the area will be greater. He had already alluded to the researches of Dr. Oliver Lodge in his (Mr. Hedges's) paper entitled "The Protection of Public Buildings from Lightning," read before the Royal Institute of British Architects on April 23rd last year, and he begged to refer those interested to his concluding remarks under the head of Practical Questions, in which he had slightly altered Dr. Lodge's rules and added some of his own.

Park Lodge, Hull.—The lodge by Mr. Joseph H. Hirst, illustrated on the previous page, is proposed to be erected at the Anlaby Road entrance to the West Park, Hull. The ground storey is of red brick, and the upper storey of stucco. The roofs are covered with red tiles. The lodge contains parlour, kitchen and the necessary offices, all under the main roof, and three bedrooms on the first floor. Provision is also made for ladies' w.c.'s in a separate building. Mr. Hirst is the city architect of Hull.

By-Laws for Rural Buildings.—Mr. Long stated, in reply to a question in the House of Commons last week, that he was preparing a series of model by-laws with respect to new buildings in rural districts, which will deal only with matters most in need of control for purposes of health. The series is intended as a guide to rural district councils wishing to make by-laws on the subject, and will be specially applicable to places consisting of scattered dwellings. It will be competent to a district council in any particular case to propose any modifications and additions which appear to them necessary to meet the circumstances of the locality. The model is only intended by way of suggestion to the rural councils, with whom rests the initiative as to making by-laws.

ABERDEEN SLATERS AND ARCHITECTS.

A MEETING of Aberdeen master slaters was held recently to consider their position in regard to a circular issued by the Society of Architects raising points of considerable interest to the trade. The circular referred to is as follows: "At the annual general meeting of the society, held on March 3rd, the following motion was put to the meeting and carried: That the following method of schedule measurement for slater work shall in future be adopted by members of the society—Measurement to be nett, with the following allowances added, viz.: 18in. at piends and valleys, 6in. at eaves, 6in. at skews ends, window sides, and other voids. All circular work to be stated separately. It was also moved and carried—That, in consideration of fourteen master slaters having agreed to tender to none but members of the Aberdeen Society of Architects, members of the society shall in future not send schedules to or receive tenders from others than the said fourteen master slaters, or from those who may join the Slaters' Association to be formed by them, this agreement to apply only to work within the city boundary. At a subsequent meeting of the council of the Architects' Society, it was intimated that the number of master slaters who were willing to conform to the above agreement had been reduced to eleven. The council nevertheless seemed to let the resolution stand, the names of the following masters being substituted for the fourteen who had previously intimated their willingness to abide by it: Alexander Murray, King Street; A. E. Merson, Bon-Accord Street; George Farquhar, Union Row; Alexander Law, Little Chapel Street; William Reid, Osborne Place; J. & A. Milne, North Broadford; Alexander Smith, Albyn Lane; William Coutts, Chattan Place; A. Harper & Sons, Summerfield Terrace; George Davidson, Thistle Street; and Charles Maitland, Union Grove. Members of the society are therefore requested in future to conform to the above resolutions. John Rust and A. H. L. Mackinnon, joint hon. secretaries."

The promoters of the recent meeting held that the eleven master slaters who had intimated their willingness to abide by the resolutions of the architects formed only a third of the master slaters of Aberdeen, and had no authority to voice the opinion of the whole trade. The names of the other firms or individual masters not mentioned in the circular quoted were as follows: Messrs. Adam & Co., George Bain, Peter Brodie, James Clark, John Copland, William Copland, Messrs. Currie & Co., Messrs. James Duncan, J. D. Farquhar, James Forbes, Duncan Grassick, James Harper, J. M. Macdonald, Adam Martin, Merson & Stewart, Forbes Morrison, George Steele, James Wilson, James Wright, Robert Stuart, John Durnin, William Clark and William Sheret.

Of the last-mentioned masters, fifteen were present at the meeting. Mr. Peter Lewis (of Messrs. Adam & Co.) was called to the chair, and Mr. J. D. Farquhar was appointed secretary of the meeting. A general discussion took place with reference to the circular and the resolution of architects, the general opinion being expressed that the architects could not have been aware of the fact that all the master slaters in town had not been consulted with regard to their proposals. Some of those present said they had never heard of those proposals until after the circular had been issued. The architects, it was stated, had since themselves learned that the masters who had agreed to their proposals did not represent the whole of the trade. It was also stated that every master slater in Aberdeen had been invited by advertisement and circular to attend that meeting, so that no hole-and-cornerism could be alleged.

Mr. D. Grassick moved "That the members present form themselves into an association to take action on their own account, and to approach the architects in regard to the proposals," and the motion was unanimously carried. Office-bearers were then appointed as follows: President, Mr. Robert Kincaid (Messrs. Currie & Co.); vice-presidents, Messrs. Forbes Morrison and D. Grassick; secretary, Mr. George Mackenzie, solicitor (Messrs. Mackenzie & Wilson); treasurer, Mr. Robert Stuart; committee, Messrs. James Wright, P. Lewis and James Wilson.

ROYAL VICTORIA HOSPITAL, BELFAST.

DESCRIPTION OF THE BUILDINGS.

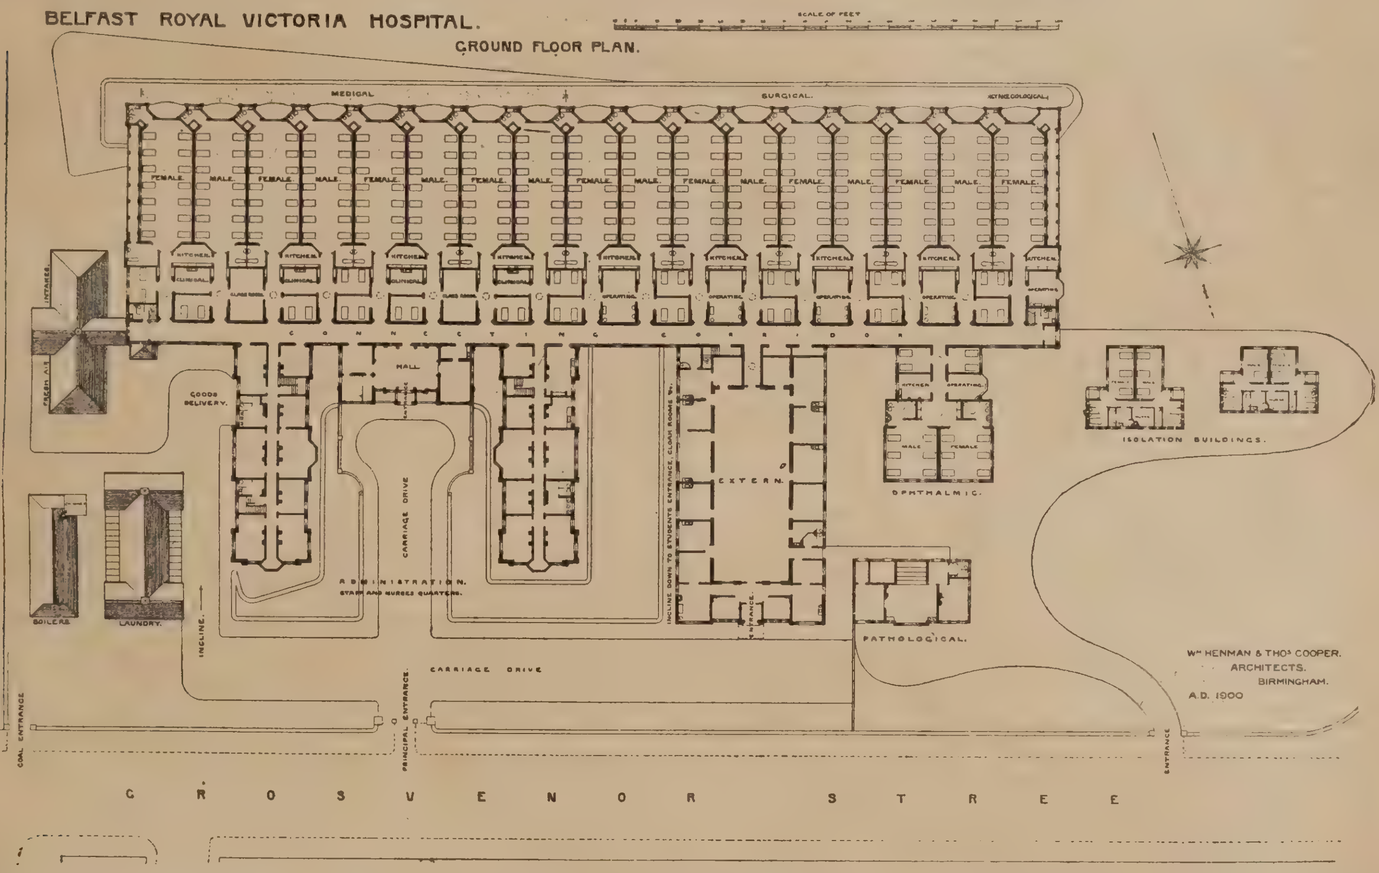
THE new Royal Victoria Hospital at Belfast—of which we give a plan below, and, in the centre plates, views of the administrative building and wards—is now in course of erection from the designs of Messrs. William Henman & Thomas Cooper, architects, of Birmingham, the contractors being Messrs. M'Laughlin & Harvey, of Belfast and Dublin. Arrangements had been made for the laying of the foundation stone on April 18th last by the Prince and Princess of Wales on behalf of her late Majesty Queen Victoria, but the royal death necessitated the abandonment of the ceremony. His Majesty the King has, however, graciously expressed his desire to lay the foundation stone at a later date. Accommodation will be provided for 300 patients, eight resident medical and surgical officers, seventy-six nurses, and thirty-two male and female attendants and servants. The principal entrance to the site, which is six acres in extent, faces Grosvenor Street. The administrative department of four storeys and basement, in three separate buildings on the north side, provides a spacious entrance hall (above the porch of which is a statue of Queen Victoria), and accommodation for the resident staff, the nurses' home, the attendants' and servants' quarters, the dispensary and the kitchen department. On the south side of a main corridor, running east and west, are the wards, side by side without intervening space, and practically under one roof. Each ward is for fourteen beds, eight being for medical, eight for surgical, and one for gynæcological cases, with their accessory rooms approached by branch corridors. The wards are alternately arranged for male and female patients.

In connection with each group of four medical wards there are a large classroom and two clinical rooms, and to every pair of surgical wards there is an operating room. On the north side of the main corridor are the ophthalmic wards—two of six beds and two of two beds; also an operating room. Near each of the seventeen large wards is a separation ward for two beds. A ward kitchen serves for each pair of wards, except for the gynæcological cases, where the department is self-contained, with separate operating room. Bathrooms and conveniences are attached to all the principal wards, and linen cupboards and stores for patients' clothing are provided. Two detached buildings are for isolation purposes, one being for six beds, the other for four, with kitchens, convenience and nurses' bedrooms. To each of the fourteen-bed wards there is a large window at the south end, opening on to a balcony, from which there is a view over park-like grounds to the hills beyond, and from end to end of the wards there are lantern lights; consequently, as the only lofty buildings are on the north, whatever sunlight there may be throughout the day is admitted to the wards, or may be regulated to requirements by the provision of green draw-down blinds. The compactness of the arrangement of the wards not only simplifies administration and reduces labour to a minimum, but it lends itself to the "Plenum" system of ventilation more readily and with more certain results than with wards one above another in buildings of several storeys.

To the west of the administrative buildings is the out-patients' or "extern" department, consisting of a large waiting hall with a number of medical and surgical consulting rooms around on the ground-floor level; while in the basement there are retiring rooms for the use of students attending the Hospital. The appliances for securing ventilation are in a separate building at the east end of the main corridor, connected with the Hospital at the basement level by the principal air-inlet duct, which is 20ft. high by 9ft. wide at that end. The air in-take building contains what may be regarded as the lungs of the hospital, because by means of the appliances there installed the whole of the fresh-air supply is drawn in, filtered through moistened screens, warmed in cold weather, and forced on by means of powerful air propellers in quantity sufficient to change the whole of the air in the Hospital seven times per hour in winter and ten times per hour in summer without opening any windows. The appliances are all in duplicate, each of sufficient capacity or power to supply the minimum amount of air required, so that all necessary cleaning, rest and repair of the machinery may take place without stopping the air supply.

The knowledge and experience which the architects have acquired of "Plenum" ventilation have enabled them, in conjunction with Mr. Henry Lea, the consulting engineer, to adopt improved appliances, and to simplify and cheapen the cost of maintaining their efficiency; and, by utilising the exhaust steam from the engines in securing the necessary supply of hot water throughout the establishment, it is estimated that very little additional cost will be incurred for a system of ventilation far more efficient than can be obtained by the ordinary methods.

There will be a complete steam laundry in a detached building on the premises, together with disinfecting apparatus and a destructor. The pathological department, including a laboratory, post-mortem room, mortuary and a viewing room, divided off by a glazed screen, is provided for in another detached building. For the elevations stone is used, combined with specially manufactured sand-faced bricks of a good red colour. The cost per patients' bed will not exceed £300, an exceedingly low figure for such a complete and up-to-date hospital.



BELFAST ROYAL VICTORIA HOSPITAL.

GROUND FLOOR PLAN.

THE ARCHITECT AND THE GLOVES.

THE Paris correspondent of the "Daily Telegraph" asks the following question: Can a railway guard be compelled by passengers to wear gloves? A squeamish architect, who lately travelled in the Dieppe-to-Paris express, considers that the answer is in the affirmative. The Courts, however, have decided otherwise. On the occasion referred to the gentleman was asked for his ticket by the guard who wished to punch a hole in it. He was just going to comply when a look of horror came over his face. "Where are your gloves?" he exclaimed, in a shocked tone. But the railway official bluntly replied that he had not any gloves, that he was not going to get any, and that his bare hands were good enough for the likes of the architect. The latter after this declined either to continue the conversation or to give up his ticket until the guard should put gloves on. As the guard never did so the ticket never got punched, but the passenger received a summons to appear before the magistrate for his refusal to comply with the company's by-laws. In court the architect explained his case in the politest but firmest way possible. But the judge fined him £4.

NEW BUILDINGS IN MANCHESTER.

ANOTHER CRITICISM.

IN our issues for November 14th and December 26th last we took the liberty of reprinting from the "Manchester Guardian" two criticisms of buildings recently erected in that busy city. A further criticism has lately appeared, which we give below. It is much to be desired that intelligent comment of this kind should more often be seen in the columns of the daily press, against some of whose members a heavy account lies for setting up before the public standards of architecture which are entirely false.

Our Manchester contemporary remarks: St. Athanasius used to say, "One must not be tired of repeating." The same faults reappear, so that very much the same criticism has to be applied again and again to the buildings rising up in our midst. At Old Trafford, on the way to the Ship Canal, is a fine pile of building bearing the name "Duckworth's, Manufacturing Chemists," but its redness is too uniform. The walls and front roofs and the doorways and window openings are all of a vivid red without any relief, and such good material has been used that the vividness of the red will probably remain. Had there been better detail—for the detail is not equal to the general design—and if two well-chosen colours (say such as there are at St. Mary's Hospital) had been used for the terra-cotta and brickwork, and brown or purple tiles for the roofs, this building would have taken fairly high rank. There are slated roofs behind. It would have been better to have chosen slates or tiles, and have kept to one, for the same building.

Grand Opportunities.

Here and there in Manchester are some wonderfully good sites. Look at the north end of Albert Square, or the east side of the Cathedral Yard, or the north and south ends of Ardwick Green, or the south-east corner of Albert Square. How have these grand opportunities been used or missed? In Albert Square the great mistake made in Liverpool is not being repeated, namely that of trying to design the range of new buildings in the style of the Town Hall. Civic Buildings, though not very powerful or original, is a distinctly satisfactory building in its general treatment and careful detail. But why are the more easterly chimneys brick? They are much seen. And why are all the chimneys so commonplace? There are endless examples of good chimneys all over the country and abroad. In many a small town or village beautiful chimneys are to be seen, the making of the house or shop or lodge or cottage of which they are part. In days gone by chimneys were welcomed in a design, and they helped much in imparting life and vigour. Now they have come to be regarded by the public with regret or reproach, and the feeling is almost justified by the unworthy treatment they often receive. In this Albert Square building, too, there is, in the side street, brick just "butted" up to the stone, with no more blending than of oil and water. The skyline has obviously been considered, but not worked out quite sufficiently. The roof dormers would have been better for giving light, and also in appearance, if of twice or thrice their size.

The Whitworth Hall of Owens College

grows on one as it grows. There is very little carving, and that little is well placed. The heraldic work will perhaps yet be a little more boldly cut. At Oxford and Cambridge the college arms are carved, as a rule, with daring boldness, yet with such excellent effect that others might well take courage. In this building, too, there is an entire avoidance of the sort of "ornament" so much in vogue, and used so often to hide the poverty of design. The south gable promises well, with its fine window flanked by plain masonry on either side. In this hall there is dignity without the cast-ironness which has hitherto abounded at Owens College. The seven pedestals, presumably for statues, on the east side of the hall lead one to hope that the figures will be very boldly and vigorously sculptured, not too smooth and delicate for the height—as are, for instance, the recent figures for the north-west tower of York Minster. One is sorry that in all this vast group of costly buildings the chimneys are in no case treated with the respect due to a chimney.

Those of the public who have not made a serious study of architecture should remember that the exterior taken alone is not architecture. The plan and arrangement of the interior must be considered in connection with the outward manifestation. A fine front may be little else than a mask, and however admirable in its way that may be, it is not architecture. The genius of Sir Charles Barry enabled him to clothe a convenient plan and effective interior with a stately and graceful outward form—witness St. Stephen's, Westminster, or many London clubs, or our own Athenæum before it was maltreated. Bridge Street Chambers have at the street level six shops with a centre door, the whole with a brick and stone front. The conditions and requirements are such as to lend themselves to an effective building, yet the result is somewhat tame and commonplace. Another building of much the same sort is Central Chambers, in Brazennose Street. Brick and stone make an admirable combination in a facade, but much depends upon the way they are disposed. The great block of building, the Corn and Produce Exchange, with shops, on the east side of the Cathedral Yard, has, with the Cathedral in the foreground, one of the best sites for architectural effect in the city. But it is all stone. Is it to match the Cathedral? one wonders. It would have been better for both had much of it, if not nearly all, been red brick. A praiseworthy attempt to design on an exceptionally bold scale has been made; but it misses complete success, though it comes as near it, perhaps, as the National Liberal Club on the Thames Embankment.

Though in a confined and difficult site, it looks as if

St. Mary's Hospital

in Oxford Street was going to be, in outline and general design, one of the best of our brick and terra-cotta buildings. The colouring, too, is good, and will probably, if treated to the Lancashire yearly wash, remain so. It is not too magnificent to be suitable for a hospital, yet there is nothing too plain or paltry about it—except the back bit on the canal bank, which really does cry shame. The architect is a strong man; why did he not put his foot down and demand permission for a treatment consistent with the street front, if less costly than it? As to the washing of our buildings, when the best brick is used, rain, where it can get at the bricks, will keep them fairly clean. It is obvious, therefore, that careful washing of those parts which are more or less sheltered from driving rain would be effectual. With stone it is otherwise, in such smoke-laden air as this. Stone buildings, like trunks of trees, in Lancashire become and remain very much of one colour, if black be a colour.

A Conspicuous Building.

One of the most conspicuous of recent buildings in Manchester is that on the south side of St. Mary's Gate. Here there has clearly been liberal expenditure, but the effect obtained is not commensurate with the efforts made in attaining it, and the ponderous mass of superstructure, seemingly carried on the thinnest and lightest of woodwork, excites (though no doubt it is really strong enough) an uncomfortable sensation. Higher up, again, the pair of wooden oriel windows of slim construction have the appearance of sustaining heavy stonework above. There is here a great deal of carving and ornament likely to catch the dirt.

Bridges.

All over the city one sees bridges—usually covered—high up, for access from one warehouse or other building to another. Such bridges might always be (without going as far as Lucerne for a model) picturesque and delightful. Yet is there one that answers this description? Even at the temple of learning in Old Millgate the covered bridge leading from the southerly part to the northerly is not only as hideous in itself as it well could be, but it partially conceals and wholly mars the ancient and picturesque east gateway to the Chatham Hospital. It might have been put there to show the boys of the Grammar School what should be avoided. One thing, by the way, which is not avoided enough in our recent buildings is "the diseased desire for uniformity," which craves to make everything correspond with something else. The name of a suburban villa is often on both gate piers, even if not 1½yd. apart. It would be more useful if, the name of the house being on one, the number of the house and the name of the occupier were on the other.

New Churches.

There would be more churches to notice were it not that a "tin tabernacle" so often acts as *locum tenens* for a brick or stone building. There is the easterly portion of a church in the Wilbraham Road, south of Manchester. It looks fairly church-like, and there is a welcome absence of vulgarity. In St. Werburgh's brick and terra-cotta are mainly used, and the effect would have been better if the red bricks and the terra-cotta had been brighter. This church has the fault, common to so many such buildings, of being a rather commonplace stone design carried out in plastic materials. It adds much to the interest and artistic value if the materials are allowed to rule, or at least to influence, the design. Canon Hoskyns at the Town Hall recently spoke up well for the right kind of churches. He showed the benefit to the community of dignified and beautiful churches, especially in squalid districts. He dwelt, too, on the importance of making the inside specially impressive and devotional. It would be well if the Vicar of Bolton would speak oftener and at greater length on this subject, which he is so well qualified to handle. If only the Chair of Architecture at Owens College, which seems to come nearer, be established, and be, as it doubtless will, worthily filled, it is to be hoped that in time not only will more of our architects learn architecture as an art, but that the public will become sufficiently interested in the art to be able to distinguish good work from bad.

WESTON-SUPER-MARE ELECTRIC-LIGHT STATION.

THE scheme for providing Weston-super-Mare with electric light undertaken by the Weston-super-Mare and District Electric Supply Company, is now rapidly approaching completion. Continuous current, generated at the supply station in Locking Road, is brought by means of concentric feeders to three feeding points—one situated at the junction of High Street and Regent Street, another in the Knightstone Road, and a third in Beach Road at its junction with Ellenborough Park. At these points a supply of current is given to the three-wire distributing network, from which services are taken to consumers—the arrangement being such that the latter can be supplied at a pressure of either 230 or 460 volts to suit requirements. At various points on the network disconnecting fuse boxes are placed, enabling a street or portion of a street to be cut out for connections to be made without any interruption to the general supply. Three spare earthenware conduits are also laid to various points to provide for extension feeders. The contract for the whole of the work in connection with the mains has been carried out by Messrs. Callender's Cable and Construction Company. The architectural design of the generating station was placed in the hands of Messrs. Wilde & Fry, who are also architects to the Penarth Electric Lighting Company. The builders were Messrs. Charles Taylor & Sons. The front of the building faces west, and is occupied by commodious offices for engineers and clerks, and store-room. The engine-room, measuring 44ft. long by 25ft. wide, provides accommodation for two dynamos coupled to two high speed compound engines. The dynamos and boosters, together with the main generators and engines, were built by the Brush Electrical Engineering Company of London and Loughborough. The switchboard runs along the north wall of the engine-room. A 5-ton travelling crane traverses the engine-room at a height of 18ft. 6in. Adjacent to the north wall is the accumulator-room. The boiler-house adjoins the south wall of the engine-room, and contains two Babock & Wilcox water-tube boilers. They are supplied with water from an overhead tank by means of motor-driven pumps. The exceptionally hard Weston water is reduced to under 5 degs. Clarke, by means of a Desrumaux water softener. The lighting of the generating station has been done by Messrs. Bryant & Sons The entire work has been carried out under the supervision of Mr. S. G. Leech, A.M.I.E.E., the company's engineering manager, with the assistance of Mr. H. Holman.

CHRIST'S HOSPITAL.

Mr. ASHBEE'S PLAN.

DISCUSSION grows apace in regard to the proposed demolition of Christ's Hospital, and the clearing of the site for the erection of business premises (see p. 258 of our last issue).

Mr. C. R. Ashbee, chairman of the London Survey Committee, writes as follows: I have laid before the National Trust a plan for the treatment of the site which, though it may not yield to the supporters of the Bill now before Parliament the uttermost farthing for the estate and everything on it, still may claim to give them a very ample return. and to be drafted in the public interest without being unduly unfair to the Christ's Hospital authorities.

Broadly, the scheme implies the cutting of a new street east and west from Little Britain to Holborn Viaduct, and another north and south from the new street to Newgate, while it arranges for ample widening of Newgate Street along its north side. By this arrangement the following objects are gained:

(1) One-third of the existing open spaces are retained.

(2) The claim of Bartholomew's Hospital is satisfied, the northern portion of the estate being sold to the Hospital, together with an excellent approach, while in addition the Hospital gets the advantage of a good open space in front of it.

(3) The Post Office lights are protected.

(4) The most interesting portion of Christ's Hospital buildings, the Sir Christopher Wren parts, and the remains of the old Greyfriars' Monastery, are preserved, and could be acquired by the London County Council for a civic museum.

(5) The other Wren portion of the estate is saved, the Governors' Court Room remaining as such, and the existing buildings used as offices for Christ's Hospital authorities.

(6) Newgate Street is widened the whole stretch from Giltspur Street to Christ Church Passage, and the widening might be extended to the Post Office Station.

(7) Any remaining portion of London Wall and the Town Ditch is saved as an historic record to the City.

(8) Newgate Street traffic is relieved by the new street from Little Britain to Holborn, the idea being later on to widen Little Britain with a view to getting a direct route from Aldersgate Street to Holborn Viaduct.

(9) A fine architectural feature is secured to the City by isolating the Greyfriars' Monastery, throwing the Wren facade open to Newgate Street, with Christ Church and its open space in front. and the other open spaces at the rear.

(10) A good block of offices and shops can be planned in the triangle made by Newgate Street and the other streets on the western side of the property at a large profit to Christ's Hospital.

(11) By thus handling the whole site, in part for building and in part for public open spaces and new roads, Christ's Hospital will be able to receive full value for the bulk of their property.

The only thing that is to be regretted in this scheme is that the Great Hall, which, though comparatively modern, is a very fine and stately building, has to be sacrificed.

A plan showing my scheme may be inspected at the offices of the National Trust, 1, Great College Street, Westminster, by anyone interested, and I trust that before proceeding with their present Bill the Governors will carefully consider whether some such method of dealing with the site is not practicable.

The "Pall Mall Gazette" makes the following remarks respecting the new buildings now being erected at West Horsham from the designs of Mr. Aston Webb, A.R.A.: "As you approach the schools from the road from Horsham the thick red line of buildings strikes you as appallingly ruthless in its ugliness. Red, red, red—red everywhere! Red walls surmounted by red tiles, except in the case of one merciful exception—the great dining-hall, the green Cumberland slates on the roof of which are a mercy to sorely tired eyes.

"Some day the red nakedness of this glaring patch of buildings may be screened by relieving avenues of green; but for the next generation, we fancy, the eyes of all concerned will suffer for it. It seems like straining at a gnat to have cut down the stone decoration originally proposed; as against the hundreds of thousands which will have been spent by this time next year the saving of a few tens of thousands was not worth the candle at such a cost! Æsthetically we fear the new schools come near failure. But there is another side to the picture. For the grouping of buildings, with a view to convenience in the practical working of all sides of school life and to the health of the boys, we believe the new Christ's Hospital will prove a complete success and an eye-opener to school authorities for the future. The centre quadrangle—the hub of the school life—with its school hall and flanking classrooms, is skilfully connected with the residential blocks by means of covered ways; the boarding-houses are models of convenience and sanitation; and there will be a wealth of playing-field accommodation. Library, drawing school, science school, common rooms have been provided on a liberal scale and on the most approved principles. Wherever the boys' interests are concerned a free hand has been displayed. This makes it the greater pity that the work has not been completed in true proportion. The docking of the external ornament to effect a comparatively small saving was poor policy, and equally so is the somewhat meagre way in which the requirements of the teaching staff are to be met. Married quarters are inadequate; and in the houses that are provided one cannot fail to notice the niggardly scale on which reception-rooms have been planned, just as though there was not plenty of ground for the using. In buildings destined in the ordinary course of things to stand some two or three centuries a little less of bricks-and-mortar parsimony would have been seemly."

ELECTRIC LIGHTING.

Some Particulars of Mr. Tesla's New Lamps.

MANY years ago Mr. Tesla was struck by the idea of producing artificially those oscillations of enormous rapidity in the minute particles of matter in a very attenuated, *i.e.*, gaseous, state, which, after being communicated to the ether, are transmitted by its waves and reach us in the form of light.

The theory itself had occupied the attention of some of the greatest scientists long before Mr. Tesla's time, but its practical application remained an unsolved prolem, excepting some laboratory experiments foreshadowing a solution, the most brilliant and promising of which were those successfully carried out by the young Austrian inventor himself; while to find the means of producing and utilising these oscillations in a simple and economical manner for the production of light, and to make this light a commercial success, was the chief among the many difficulties that had to be overcome ere there could be a question of bringing this form of illumination within the reach of the public at large.

This difficulty, Mr. Tesla informs us through the "New York Sun," has now been overcome, and he is able to produce light on the basis above indicated at a cheaper price than that which we have to pay for light derived from any of the sources used for illumination at present. The general features of a domestic installation for producing this new form of light are the following: The electric current, continuous or alternating, is derived in the usual manner from the street mains, but instead of being directly conducted to the special spiral-shaped lamp it first reaches an apparatus in which it is transformed into the required oscillations of high frequency, which reach the metallically-coated ends of the spiral and, entering the glass tube, creating in the interior corresponding oscillations of the same rapid sequence, and so producing light.

There is no incandescence due to combustion of the gas, which, of course, would affect the life of the lamp and require its renewal. Those lower forms of waves known as heat waves are totally absent, or, at all events, not present in any perceptible degree, and the lamps remain unaltered for years, since practically the whole energy is converted into light. The economy, therefore, of this process of illumination, as far as the utmost utilisation of the source of light in the form of light is concerned, approaches the ideal.

This light resembles sunlight in its hygienic effect and ozonises the atmosphere, an effect which, however, can be at will either prevented entirely or increased to a degree just suited for the purification of the air, such as might be required in hospital wards. And last, but not least, the lamps may be fed by a single wire, and even, under certain circumstances, lighted without wires; so that the lamp may be moved from one place to another without hindrance.

PAISLEY ABBEY RESTORATION.

THE restoration of the ancient and beautiful Paisley Abbey and the clearance and improvement of its highly inartistic surroundings has been undertaken, but it will probably be some years before the work is accomplished. It is estimated that the restoration will cost £40,000, and the improvement of the grounds, including the removal of unsightly buildings, at least about £20,000. Already very substantial and visible progress has been made. By the end of the present year there will be thoroughly completed one section of the work, which has been divided into three. These divisions, as applied to the Abbey itself, comprise, first, the restoration of the north and south transepts and the erection of the under portion of the tower; secondly. the rebuilding of the choir; and thirdly, the building of the superstructure of the tower itself. The work is being carried out under the guidance of Dr. Rowand Anderson, Edinburgh, who carried through the restoration of Dunblane Cathedral. Mr. William Middleton is the clerk of works. So far as the first section is concerned, the work of the mason and builder is almost complete. The under portion of the tower has for the time being reached its level, rising to a height of 72ft., flush with the apex of the roof of the existing nave. The superstructure of the tower will be the last of the sections to be undertaken, but when completed it will reach the lofty height of 156ft. from the ground. The north and south transepts have also their masonry completely restored, and roofed. One of the objects of the whole work is, of course, the extension of the accommodation for the Abbey congregation, which has hitherto been necessarily limited to the nave, the only habitable portion of the fabric. With the completion of the transepts and under tower a very considerable area will be added to the available portion of the building.

The under tower is altogether new. It is erected on four massive stone piers, 9ft. square, having a depth underground of about 14ft. These piers rise to a height of 30ft. to large moulded caps, from which spring the four great arches forming the roof. From the caps to the soffit of the arches is a curve of 17ft.. and from the soffit to the apex ring of the roof about 6ft., the height from floor to apex being thus over 54ft. From the side of the north-east pier a circular stair rises to the tower. Branch passages will encircle the whole church, giving access to all the different levels. On the first floor of the tower is a chamber 31ft. square with narrow slit windows; above this is a second and third floor, which complete the present height. The present operations extend to the famous Sounding Aisle In the course of the work it was found that its north wall, which joins the transept, was in a much less stable condition than had been suspected, and considerable difficulties were encountered owing to the state of the foundation. The aisle has always been a self-contained chamber, but the masonry of the two arches in the north wall has been permanently removed, giving immediate access to the transept.

Besides the larger operations, smaller repairs are being executed. Windows in the north and south walls of the nave are being renovated, broken portions of the mullions and tracery being replaced. The magnificently-traceried old window in the north wall of the north transept was not included in the present contract, but it is also receiving the attention of the renovator. The foundations were in a bad state, and they are being underpinned. As a matter of fact, the wall is about 6in. off the plumb, and but for the strengthening it is undergoing, its condition might cause anxiety. It is understood that a stained-glass window will be inserted when it is thoroughly repaired. The stone being used in the new buildings is from the quarries of Blackpasture, in Northumberland; Grange, in Fife; and Giffnock; with white spot from Beith quarries. In the course of the work of excavation many relics of past ages have been discovered by the workmen. One of the most interesting was that of two finely-chiselled stones, 5ft. 8in. by 1ft. 10in., found at the bottom of the foundation of the west pier lying side by side in a bed of sand. On the face of each are elaborate carved crosses, as plainly discernible as if executed but a short time ago. whereas it is computed that the stones are at least 600 years old.

Not the least important part of the whole undertaking is the projected clearance and improvement of the surroundings of the Abbey and the Town Hall on the opposite side of the street. The mean old houses in Smithhills Street, bounding the churchyard on the north, will be swept away, opening up good views of both buildings. The Abbey Close U.F. Church, which is opposite the Abbey, adjoining the Town Hall, together with a number of neighbouring buildings will be pulled down, giving from Dunn Square an uninterrupted view of the whole Abbey front. The houses, outhouses, &c., from the Place of Paisley in Abbey Street to the Graham Institute in Cotton Street will also be cleared away. Afterwards the churchyard will be laid out and maintained as an open space, and surrounding grounds will be similarly treated.

NEW Y.M.C.A. PREMISES AT BURTON.

NEW and more commodious headquarters for the local Y.M.C.A. are being erected in Burton. The new premises extend from High Street to Friars Walk, with a frontage the whole depth along Whitehurst's Passage. The main entrance will be in High Street, and leads from the entrance passage into a large entrance hall, about 20ft. square; from this entrance hall access may be obtained to all parts of the premises. On the ground floor will be found a private room, to be utilised for the general secretary's office, which will be so furnished and fitted that the secretary will be able to see everyone who may enter the building. Beyond this room is a large recreation and tea room, boiler house for the heating apparatus, and a complete lavatory block with bath-room, &c. Connected from the entrance hall by means of a glass-covered corridor is the gymnasium, the length of which is 48ft., the width 29ft., and the height to ceiling 19ft. This room will be provided with a glazed brick dado and a boarded ceiling, and is fitted with strong bearing pieces in the roof for receiving the various gymnastic appliances. The remainder of the ground to Friars Walk is occupied by the lecture hall (82ft. long, 30ft. wide and 26ft. high to the ceiling). This large hall will have a wood-block floor sloping from the entrance end to the platform, and will have a wooden dado 6ft. high; the roof will be of heavy pitch-pine timbers, resting on carved stone corbels, and all the woodwork is to be stained and varnished. Entrance and egress may be obtained by means of five doorways in this hall, and all the doors are made to open outwards. In connection with this hall are gentlemen's and ladies' cloak-rooms with lavatories attached. On the first floor, which is approached by a stone staircase, is provided a well-lighted reading room, with an opened timbered roof, and the various other rooms consist of committee-rooms, class-rooms, photographic studio and dark-room, with rooms for the caretaker. In addition to the portion of the premises occupied by the Y.M.C.A., other portions of the premises have been let off into suites of offices and a café restaurant, with its kitchen in the basement. This portion is well built in cement-concrete and white glazed brick, and in excellent light is supplied by the prismatic pavement lights. The whole of the premises will be lighted by electricity. The general contractor for the works is Mr. R. Kershaw, of Princess Street, and his sub-contractors are Mr. A. Geary, of Ordish Street (for the joinery), Messrs. T. Turner & Son (for the plumbing and painting), and Mr. T. Biddulph (for the plastering and concrete floors). The architect is Mr. Thomas Jenkins, of 35, High Street, Bristol.

NEW CHURCH AT SUNDERLAND.

A NEW church at Sunderland is being erected, in connection with the Fawcett Street Circuit of the Wesleyan Church, at the corner of Durham Road and Tunstall Lane. The new building here, which will be known as the Durham Road Church, is to cost about £9,000, or a total, including the cost of the site, of £15,000. There is also provided for in the scheme of the circuit a new church at the top of Chester Road, which will cost £6,000; and a third in Trimdon Street, which will take £5,000 to erect. The total estimated outlay on the three is, therefore, roughly speaking, £26,000. The Durham Road Church has already been commenced, and plans have been passed for the other two, the foundation stones of which will shortly be laid. The style of architecture will be Gothic, and the buildings are to be faced on all sides with stone from Pateley Bridge, whilst the dressings will be of Blaxter and Woodburn stone with Denwich tracery. The church will be cruciform in plan, and is entered by spacious vestibules at the junction of the two roads. At each side of the main entrance is a staircase leading to the gallery, there being also a separate entrance to each transept. At the rear of the church are ministers' and choir vestries, with direct access to the pulpit and choir stalls, the organ being placed behind the pulpit. The church is being built to accommodate 800 worshippers. The benches, pulpit, choir stalls, &c., will be in the best selected pitch-pine, whilst the windows will be glazed throughout with cathedral leaded glass. Behind the church there is a spacious schoolroom with gallery running round, off which eight classrooms open. There is also a large school for infants, together with other meeting rooms. The buildings will be heated and ventilated on the most improved system, and the premises throughout will be lighted by electricity. On the left hand side of the church will be a tower and spire of noble proportions, rising to a height of 100ft. The architect is Mr. J. Jameson Green, of Adelphi Chambers, Liverpool, and the building contract is let to Mr. J. B. Stott, of Sunderland. Mr. W. A. Lowry, of Liverpool, is clerk of works. It is expected that the schools will be completed by July this year, and the whole of the buildings by January, 1902.

HETTON-LE-HOLE CHURCH.

A NEW church at Hetton-le-Hole was consecrated last week. The church is estimated to cost £5,000. The parish of St. Nicholas, Hetton-le-Hole, is one of many daughters of the old parish of Houghton-le-Spring. The old church of Hetton was built as a chapel-of-ease in 1832. In 1892 the advisability of restoring it was considered. In 1893, however, in consequence of the dilapidated state of its walls, and, further, by reason of the large increase in the congregation, it was determined to pull down the old and build a new and larger church. The new church, which stands on the site of the old one, was designed by Mr. S. Piper, architect, of Newcastle-on-Tyne, and is of the Early English style of architecture. It is a large building, and will seat 800 people. One of its chief features is a large chancel, in which, on either side, there are three rows of carved oak stalls, the work of Mr. R. Hedley, of Newcastle-on-Tyne. On the right of the chancel, looking east, is a side chapel capable of accommodating from sixty to seventy persons, in the east end of which is a stained glass window, which occupied a position in the old church. The other stained glass window, also removed from the old church, has been enlarged and placed in the south transept. The aisles of the church are narrow, with lofty arches and massive stone pillars. By the introduction of the narrow aisles and wide shallow transepts the whole of the congregation is well placed, both for seeing and hearing—in other words, the church comprises one huge nave, by means of which both priest and congregation are in full view and hearing of each other. At the west end of the church there is a baptistery, formed by an arcade of three arches, with octagonal pillars, over which is a five-light window. In the north-west corner the choir vestry has been placed—a large apartment suitable not only for the choir but also for classes, &c. The chancel is paved with black and white marble tiles, 10½in. square, the work of Messrs. Borrodale Brothers, of Sunderland. Within the sanctuary the tiling is entirely white. At the east end is the clergy vestry. The font, supplied by Messrs. Jones & Willis, London, is of Caen stone, with four marble columns. The pulpit is of carved oak, executed by Mr. R. Hedley, of Newcastle All the aisles are laid with wood blocks in herring-bone pattern. The builder was Mr. W Sparrow.

CHINESE BUILDINGS AND CHINESE WORKMEN.

ALL the world now has a deep interest in everything pertaining to China and the Chinese. In the issue of the BUILDERS' JOURNAL for September 19th, 1900, an article appeared on "The Chinaman as Clayworker and Builder," when a brief account was given of the walls of Pekin. In the building of this wall the Chinese followed a peculiar custom, borrowed from their Tartar neighbours. Whenever a workman died his body was entombed within the wall. In this manner it is estimated that 1,000,000 human beings found their last resting places in the walls surrounding Pekin.

The capital of China differs from any other city in the world. It has no towering spires or graceful minarets, no lofty chimneys or high monuments, no buildings or houses eight or ten storeys high, to be seen in the distance and to notify the traveller that he is nearing the city; nothing is to be seen from the outside but the walls, and these are obscured by the houses and trees in the suburbs.

Not only the history and customs of the people influence the style of edifice commonly erected, but religion is also responsible for a style familiar all the world over. The pagoda is peculiarly Chinese. The first thought of the Confucian after arising is to worship. There is a shrine in every house, where a tablet with the names of ancestors is kept. There the household does reverence to the memory of those who have preceded him, and prays that he may live so that those who follow him may hold his name dear.

A rich man may have a separate building for this purpose, which is his hall of ancestors; the less wealthy may have a room set aside for the purpose; and the poor usually have only a shelf, but the humble paper on the dirty shelf is as sacred to its owner as the illuminated tablet in the gorgeous hall of a rich man's ancestors.

The public temple is generally an imposing edifice, with figures of various gods, with appropriate symbols. The pagoda erected at the Paris Exposition as an exhibit of Cambodia was an exact facsimile of the hill of the Pnom-Penh, crowned by the king's pagoda, a building of gold, bas-reliefs and statues.

A profusion of rich ornamentation and an inextricable medley of allegorical figures and lotus flowers, garlands and fantastic animals—half monsters, half deities—give this pagoda a remarkable appearance. Rocks and groves protect the approach to the inaccessible deity, and even the Brahmas and true believers can only reach the summit by climbing a splendid staircase of about forty steps. At the threshold of the building, Buddha, in the beatific repose of Nirvana, seems to be awaiting offerings. The architect has tried to give the general effect of that characteristic grandeur which is found in all of the famed pagodas. Rows of wonderful decorations, in which figure the flora and fauna of the forests, mythical creatures of the Buddhistic Pantheon, cover the friezes and the bas-reliefs, invest the frontage and its accessories with that kind of extravagant and bold beauty which appears to be the result of combining the arts of India and Laos.

Of the crafts strangely followed by this wonderful nation there is much to be said. The carpenter at work and the primitive sawmill are both typical examples. The skill of the mechanics is marvellous. Foreigners are occasionally surprised in China to note the deftness of the people in many lines of handicraft, and the results accomplished in the use of cheap and crude tools and appliances; but the Chinaman, after proper training, will use Western tools, manipulate machinery, and reach results that will win him recognition for his skill and bring his services into requisition; and his faithfulness in work, his keenness of observation, his power of imitation will make these services more and more valuable.

APHORISM FOR THE WEEK.

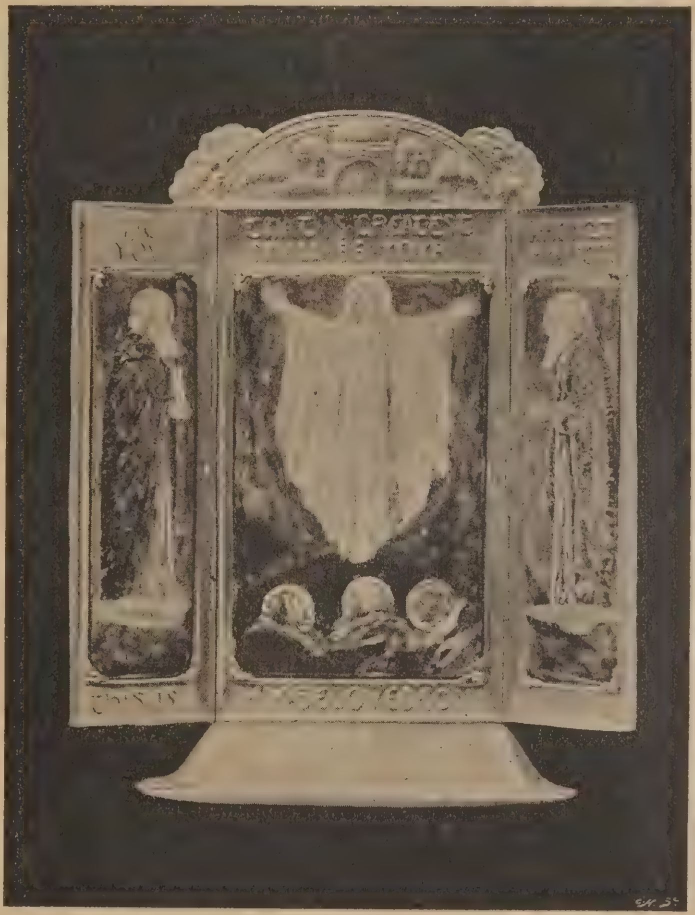
All Art is an imitation of Nature.—SENECA.

Our Plates. ASTON HALL, Birmingham, is one of the ancient homes of England "built for pleasure and for state" by Sir Thomas Holt, who commenced in 1618 and completed the building in 1635. For three generations the house remained in the possession of the Holt family, and during this time suffered considerably, as the damaged staircase and the cannon ball, both still preserved, amply testify. This was not as bad as what followed, for, getting into the hands of a building company, the park, originally of forty-three acres' extent, was being cut up for building land and the grand old avenues demolished. Fortunately our late Queen expressed a wish that the house should be saved, and, thanks to her interest, this was haply achieved, for it was bought by the Birmingham Corporation, restored, and in June 1858 thrown open by Her late Majesty as a recreation ground for the people. The Hall is now being used to exhibit various articles of interest. A slight rise after passing through the Church Lodge, with its curious ogee-shaped archway, brings one to the front of the Hall, and with its mullioned windows, quaint gables, stone balustrades, the turrets above the roofs and octagonal chimneys, quaint lodges and broad terrace forms, from wherever viewed, a pleasing picture for the artist or a wealth of detail to the architectural student. Internally the staircase, plastered ceilings, fireplaces and long gallery provide many bits worthy of study. Our illustration is from a drawing by Mr. Herbert Norman.—The houses near Bournemouth, by Mr. F. Winton Newman, are to be built with local red bricks, the upper portion to be finished with rough-cast, and the roofs covered with red tiles. The following accommodation is provided in each house: On the ground floor, sitting-room, parlour, kitchen, scullery and offices; on the first floor, four bedrooms, bathroom and w.c., and one attic in the roof.—A description of the new Royal Victoria Hospital at Belfast will be found on page 279 of this issue.

The Prix de Rome. FROM the moment a French lad enters a Paris *atelier* his thought and work combine to lead him to that alluring goal the Prix de Rome, since the winner is entitled to a course of study in the art galleries of the Eternal City. There are three stages in the competition for the prize. The first is a *croquis* in oils, the second a figure in oils, and then the great struggle begins. The successful competitors are given a subject, and, in order that their work may be evolved from their own imagination and executed without any friendly aid, each student is confined to a room in the Beaux Arts, and there for three long months he labours like a prisoner in solitary confinement. The final stage of the competition began the week before last, and the *déménagement* from the artist's own studio to his cell in the Beaux Arts is one of the most picturesque sights of Paris. All his painting properties, cooking utensils and musical instruments are packed in a fiacre, or—if he is poor—on a handbarrow, and he sets off hopefully for his lonely *loge*. Three months hence the students in some *atelier*—it may be at the Beaux Arts, it may be at Julian's School, will be sitting quietly working away at their easels, the smoke from pipe and cigarette floating upwards and encircling the model like a blue veil, when suddenly the door will burst open and a voice will cry "Victoire! nous avons le Prix!" A tumult of triumph will fill the studio, the model will be sent away, canvasses set aside, easels folded, and a *charge de cavalerie* organised. Easels will be turned into horses, and the students, astride them, with brooms, canes, umbrellas, &c., in their hands, will gallop round the throne, saluting as they pass the self-elected commander and shouting "Vive le Príx de Rome!" The pictures, sculpture, &c., are publicly exhibited before and after the judges award the prize. The successful student while studying in Rome must send a picture once a year to show what progress he is making, and if it be of outstanding merit it is purchased by the State. It may be mentioned that out of ten competitors for the Prix de Rome in sculpture this year six are pupils of the same master, M. Barrias. This is supposed to be the largest number of *concurrents* which has ever come from one *atelier*.

Preservation of Historic Buildings. MR. H. J. GLANVILLE, writing to the "Times," states that the movement for preserving the picturesque features and historic buildings of Hampstead has made considerable progress, and a memorial, largely and influentially signed, was presented recently to the Borough Council by a deputation of Hampstead residents, headed by Sir Richard Temple. "The great difficulty to be contended with," he says, "is that the Building Act gives no power to the borough councils, and but a limited power to the London County Council, as regards the control of building schemes. If a public body such as the London School Board threaten an historic building, the law obliges them to give public notice of their scheme. The result that attention is aroused, you are appealed to, and the threatened act of vandalism is prevented. But if the same building is threatened by a speculative builder he has merely to submit his plans to the district surveyor, and if the provisions of the Building Act are complied with, the plans are passed, and the historic building disappears without any notice having been given either to county council, borough council, or the public. A certain number of building schemes, however, viz., those in which the builder desires to be relieved from exact fulfilment of any of the provisions of the Building Act, come before the London County Council for consideration, and last year 2,320 schemes were thus considered. The Hampstead memorialists urge that the county council should be asked by the borough council to give early public notice of all such proposed building schemes in Hampstead where there is any reason to think that any public interest or the interest of any body of residents may be injuriously affected. In the case of historic buildings such public notice would probably result in the preservation of such of them as, because of their beauty or their literary or artistic associations, might be deemed worth saving. It is to be feared, however, that by reason of their limited powers neither the county council nor the borough councils can do much to save what yet remains of picturesque and historic London, and some alteration in the Building Act seems to be called for if the end in view is to be attained."

A Triptych in Metal and Enamels. THE triptych illustrated on this page is made of transparent enamels on copper and silver. The central figure is of brilliant pearly translucent white surrounded with night blue. The figures asleep on each side are gold, purple, green and blue. These panels are mounted in repoussé copper gilt. It was exhibited at the Royal Academy in 1899, and was made by Mr. Alexander Fisher, of 17 Warwick Gardens, Kensington, W., who is so well known for his work in recreating the art of enamelling.



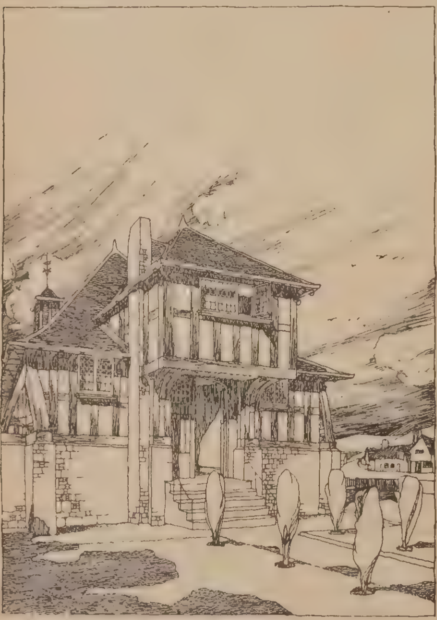
TRIPTYCH IN TRANSPARENT ENAMELS ON COPPER AND SILVER.
BY ALEXANDER FISHER.

The Queen Victoria Memorial. MR. H. DEVEY BROWNE, writing to the "Times," says: "If the statue of the late Queen is erected in the forecourt of Buckingham Palace looking down the Mall—that is, towards the north east—the face of the statue will be in shadow during the greater number of the hours of daylight, from 11 a.m., or earlier, till dusk. The sun, if it is shining, or in any other case the light, will be in the eyes of the spectators, who would certainly be much more numerous after 11 a.m. than before that hour. I do not think this has been suggested by any one better acquainted with such matters than I. It may be worth mentioning that, among existing monuments, the statue of Charles I. at Charing Cross, the Albert Memorial and the National Denkmal on the Niederwald face the south, the monuments of Bartolommeo Colleoni in Venice and of Gambetta in Paris face the west. It may be observed that I mix old and new, good and bad, for I do not presume to discuss the artistic merits, but only the aspect, of the monuments.

I think that English art cannot learn anything from modern German art—rather the reverse—so it may be relevant to mention that the monuments of Maria Teresa in Vienna and of the Emperor William I. in Berlin face the north-east. As the statue of the late Queen will be executed by Mr. Brock, it is certainly relevant to say that the statue of Her Majesty, also by Mr. Brock, recently unveiled at Hove, in Sussex, faces the south. One can judge from this figure how little could be seen of the dignified face if, looking to the north, it were illuminated only by reflected light from the roadway below. As the new statue will no doubt be under a canopy, the north side of the Albert Memorial is, perhaps, a better example."

Where the Memorial should be. HE goes on to say: "Supposing that my theory is correct, it seems that the new statue would be seen to advantage if the proposed memorial stood in the southern part of the Green Park, looking south or south-east over the large open space in front of the palace, with any arrangements of roads, terraces, and arcades that might be desirable. To refer again to existing monuments, the Albert Memorial in London and the Scott Memorial in Edinburgh are thus placed at the side of main thoroughfares, and the monument of Gambetta, though it faces the central avenue of the Tuileries gardens, is at the side of the roadway across the courtyard of the Louvre. The Niederwald monument is at the side of the Rhine and not on a promontory, as is, I believe, that of the Emperor William I. at Koblentz. The monument of Maria Teresa is at the side of the Ringstrasse in Vienna, and that of the Emperor William in Berlin—an example in other ways to be avoided—instead of looking over the open space by the river or canal, faces the long southern wall of the Royal Palace. If the memorial to Queen Victoria were placed in the position I venture to suggest, the face would be well lighted, and the background of the monument would be the trees of the Green Park instead of the very poor architecture of Buckingham Palace."

A Village Hall. THE village hall illustrated below was designed to accommodate 200 persons, with reading-room, library, scullery, stage and retiring room, and accommodation for caretaker over front entrance. The idea was to construct a purely half-timber building, the walls being built up of 9in. by 9in. posts. The hall is 50ft. by 34ft., and has a ribbed barrel roof, filled in with ornamental plaster-work. The drawing and design is by E. Stanley Mitton, of Oxford Road, Moseley, Birmingham.



DESIGN FOR A VILLAGE HALL.

Law Cases.

Claim for Alleged Negligence in Making Valuation.—In the King's Bench Division of the High Court of Justice the case of *Harding* v. *Ewing* was heard on May 4th. Mr. Solomon Harding, of Chester, brought an action against Mr. Charles Anthony Ewing, architect and valuer, also of Chester, to recover damages for alleged negligence in making a valuation of certain house property at Liscard, near Birkenhead. Defendant denied negligence. It appeared that in 1898 the plaintiff, who was the secretary of a building society at Chester, was in negotiation with Mr. Allday, of Liverpool, with the view of making an advance on four houses at Liscard. The plaintiff instructed the defendant to make a valuation of the houses, and he did so, fixing the value at £2,100. Relying on this valuation, plaintiff said he made an advance of £1,250, and agreed to pay a further sum of £100 when the road on which the houses abutted had been completed. Subsequently plaintiff discovered that the valuation was too high, and he now submitted that the defendant was guilty of negligence in making the valuation, because in arriving at his figures he relied solely on information supplied by the mortgagor. Defendant contended that he was instructed by the plaintiff to get his particulars from the mortgagor, and that as those particulars appeared to be fair and reasonable he was entitled to rely on them. He further said that his valuation was correct at the time it was made. Mr. Justice Bruce said he would take time to consider his judgment.

District Surveyors' Fees.—The case of *Corbett* v. *Badger* was heard in the King's Bench Division of the High Court of Justice on May 4th. This was an appeal against an order by Mr. Kennedy, the Metropolitan police magistrate, under the London Building Act of 1894. The appellant was the owner of land known as the St. German's Estate, at Hithergreen, Lewisham, and the respondent was the surveyor of the district. In 1899 the appellant contracted with a builder to erect some houses on a part of the estate, and he erected them. The appellant paid the sums for which the builder contracted to erect the houses, and they included any fees which the builder was liable to pay to the respondent under the Act. The builder, however, soon became insolvent, before the money was paid. Then the respondent took out summonses against the appellant, as the owner, because the statute provides that if the builder is in default with the fees the owner and the occupier shall be liable. The appellant took objection, and the summonses were not issued within six months of the time the complaint arose, and this depended upon a quantity of detailed evidence as to the progress made with the buildings. The magistrate overruled the appellant's contention and ordered him to pay £546 and costs. Hence the present appeal, in the argument of which it was urged that it was a great hardship on the appellant that he should have to pay the money twice over. The Lord Chief Justice said that in his opinion the case was one of considerable difficulty, but he had come to the conclusion that they could not interfere with the decision of the magistrate. Mr. Justice Lawrence concurred, and the appeal was dismissed with costs. Leave to appeal was, however, given.

Electric Light Boxes in Streets are Building Structures.—In the King's Bench Division of the High Court of Justice the case of *The Whitechapel Board of Works* v. *Crow* was recently heard. The case originally came before Mr. Justice Kennedy and Mr. Justice Darling last December, when, the learned judges disagreeing, it was reheard at a specially-constituted Court consisting of Justices Grantham, Kennedy and Darling, judgment being reserved. It was an appeal by the Whitechapel Board of Works from a decision of Mr. Dickinson, the magistrate sitting at the Thames Police Court in June last. It appeared that a summons was taken out by Mr. Crow, surveyor, against the Whitechapel Board of Works for not having given him notice, under Section 145 of the London Building Act, 1894, before commencing the construction of certain boxes or inspection chambers under the streets for the purpose of electric lighting. The Whitechapel Board of Works were the constituted authority under the Electric Lighting Act, 1892, and the Act of 1894 provided for a notice of any works to be carried out being sent to the Postmaster-General and the London County Council, together with plans of the proposed works. That notice was not served upon Mr. Crow, and the Whitechapel Board of Works contended that the Act of 1894 did not apply to boxes constructed in the streets under their Provisional Order, inasmuch as the Order contained a complete code regulating the materials, situation, and mode of construction of such boxes, and provided complete machinery for enforcing such regulations and work, with which special code and machinery the London Building Act of 1894 was incorporated. The learned magistrate found, as a fact, that the boxes were building structures, or works within the meaning of the section of the London Building Act, 1894, and he imposed upon the Whitechapel Board of Works the nominal penalty of 1s., and ordered them to pay £10 10s. costs. From this decision the Whitechapel Board of Works appealed. Mr. Justice Grantham and Mr. Justice Kennedy now gave judgment dismissing the appeal, with costs.

Non-fulfilment of Contract: A Nottingham Arbitration Case.—In the case of *Frederick Ingle*, trading as Dennett & Ingle, plaintiff, and *Starey's Carriage Works and Horse Repository Co., Ltd.*, defendants, Mr. Albert N. Bromley, architect and surveyor, of Nottingham, who was appointed referee in the arbitration, has now made his award. The plaintiff entered into a contract with the defendants to build a new horse repository and carriage works in Parliament Street, Nottingham, for the sum of £9,850; the architects being Messrs. Brewill & Baily, of Nottingham. These works the plaintiff undertook to complete in two separate portions, so that the existing business could be carried on uninterruptedly. He also contracted to complete the whole of the works by September 29th, 1898. Failing to complete by that date, the defendants were to be at liberty to deduct the sum of £25 for each week that the completion should be behind time by way of ascertained damages, and not penalty. It was further provided that the architects should have power to settle as to what extension of time beyond the said date they should consider fair in case the work was delayed by general strikes and lock-outs, or frost preventing the roofing-in of the building, but that these should be the only causes for any extension of time, which might be so settled by the said architects. On November 23rd, 1899, the architects gave their final certificate in respect of the contract for a balance of £867 10s., but the defendants, instead of paying such sum to the plaintiff (according to the plaintiff's contention), deducted therefrom £225 in respect of alleged ascertained damages for delaying completion, and paid only £632 10s., which last-mentioned sum had been received by the plaintiff as a payment on account, and not otherwise, leaving still due to him £225 on the final certificate. This £225 deduction was for nine weeks at £25 per week, dating from February 4th, 1999, the extended time fixed by the architects for the day of completion, to April 9th, when the works were said to be actually completed. The plaintiff contended that it was impossible to complete by the time fixed by the architects; (*a*) because he was unable to obtain sufficient possession of the site; (*b*) that drawings were not supplied to him from the architects in time for him to complete the work; (*c*) that certain sub-contracts, over which he had no control, and which were paid for direct by the proprietors, prevented him from completing the work; and (*d*) that extra time should be allowed for extra works. The plaintiff further claimed the sum of £483 5s. for these reasons, and for other items of loss. The defendants pleaded that the contract contained the following provisions: (1) That the architects' decision on all points in connection with the buildings as regards the time for completion was to be final and binding on all parties to the contract; (2) that the plaintiff was to suspend the execution of the works whenever called upon by the architects to do so on account of inclement weather, or other causes, and the architects should be the sole judges as to what extension of time should be allowed through such suspension of the works. The defendants' also denied the contentions of the plaintiff as to items *a*, *b*, *c* and *d*. The defendants entered a counter-claim for the sum of £650, in case it should be held (contrary to the defendants' intention) that the architects had no jurisdiction to extend and decide on the time for completion. This claim included rent of temporary premises, loss on advertising the opening of the new premises three separate times, and loss of business. The referee has awarded that the sum of £260 10s. shall be paid by the defendants to the plaintiff on the claim, and that the sum of £129 10s. shall be paid by the plaintiff to the defendants on the counter-claim. Each party to pay their own costs.

Unprotected Excavations.—Walter Shaw, builder and contractor, was summoned recently at Sheffield for leaving an excavation insufficiently protected. A blind man fell into a hole at the corner of Thompson Road and Ecclesall Road which had been made by the defendant's workmen. Replying to the defendant, this man admitted that he had several times fallen into excavations made by the Corporation and others. On this occasion, although no limbs were broken, he was very severely shaken. Defendant admitted that his workmen were at fault. The magistrates imposed a fine of 10s., including costs.

Alterations under London Building Act: Council Defeated.—On May 7th Mr. Justice Channell delivered judgment in the case of *The St. James's Hall Co.* v. *The London County Council*, heard in the King's Bench Division of the High Court of Justice. His lordship said the action was to obtain a declaration that a certain notice was *ultra vires* on the true interpretation of the Metropolitan Management and Building Act, which gave to the Metropolitan Board of Works, and now the London County Council, certain powers for the prevention of fire in music-halls. The Metropolitan Board of Works gave notice to the plaintiffs to make structural alterations (Mr. T. Walter L. Emden was their architect). Modifications were agreed upon, and the work was done on August 10th, 1885, the cost of the work being about £7,000. The original order of the Board included the pulling down of an existing staircase and the re-erection of another in the same place. The modification included the pulling down, but agreed that it should not be re-erected, the necessary accommodation required in case of fire being provided elsewhere. One of the arguments of the London County Council was that there was power to give notice "whenever" necessary. He (Mr. Justice Channell) did not regard that as very important, but it was an illustration of the mischief of holding that the powers of the section might be exercised, from time to time, whenever it appeared to the London County Council that there was danger of fire. If that were so, as soon as the owner had completed the work there might come a change of views of the London County Council, and the work might have to be done over again. The plaintiff company had from time to time since 1885 voluntarily made alterations in regard to seats, &c., but had done so without admitting the right of the defendants to require them to do so, and it seemed doubtful whether any of them were structural alterations. The London County Council now required fresh work to be done at a cost estimated at £4,000. On the whole, he came to the conclusion that the plaintiffs were right in their contention; he thought the London County Council had only power to order alterations if such could be carried out at a moderate cost, and if, when done, they would remedy whatever defects existed. He considered that the word "whenever" in the section was fully accounted for. The London County Council were to exercise the power given whenever they chose, but when they did exercise it their decision was final, not only as to the works required but as to those works being sufficient. He therefore thought the London County Council could not serve the second notice in respect of the works they required to be done, and he must give judgment for the plaintiffs with costs. He presumed the declaration would be sufficient. The declaration asked for by the plaintiffs was then made, and the defendants directed to pay the costs.

A Derby Building Dispute.—The case of *Ford & Co.* v. *Bemrose & Sons, Ltd.*, was recently decided in a Divisional Court of the King's Bench Division. The defendants, who are printers of Derby, instructed Mr. Ernest Ridgway, an architect, to prepare plans for the erection of certain works in Park Street, Canal Street and Carrington Street, Derby, and to invite tenders for the erection of the works. Plaintiffs, who are builders at Derby, tendered, and their tender was accepted, and a contract dated May 25th, 1895, was entered into by which the works were to be completed by May 7th, 1896. The total amount of the contract was £10,559. On April 1st, 1897, the architect gave a final certificate certifying that a balance of £1,530 was owing to the plaintiffs from the defendants. Plaintiffs were dissatisfied, and various disputes arose which were eventually referred to arbitration. The arbitrator found that the quantities set forth in the bill of quantities upon which tenders were invited were insufficient, and that the plaintiffs did not verify the quantities, and were not aware that they were deficient, and that they tendered and entered into the contract upon the assumption that the quantities were correct. He found that various alterations and deviations of the work were decided upon during the progress of the work, and the sum of £3,281 ought to be added to the contract price in respect of such alterations and deviations. The total value of the works executed by the plaintiffs was £13,840, and the amount already paid them was £8,750, leaving a balance alleged to be due of £5,090. The questions for the opinion of the Court were whether, in ascertaining the amount to be paid by the defendants to the plaintiffs, regard was to be had to the usage in the building trade, whether the plaintiffs were only entitled to be paid the sum of £10,559 mentioned in the contract, with deductions or additions in respect to alterations or deviations from the original plans determined upon during the progress of the work, or whether the plaintiffs were entitled to be paid the value of all the works actually executed by them at the prices upon which the contract was based. Their Lordships held that the plaintiffs were entitled to the full amount of £5,090, not on the ground of any trade usage or custom, but on the question of breach of contract they thought plaintiffs were entitled to recover in consequence of the incorrectness of the quantities submitted to them. The costs of the special case were to be the plaintiffs', but the costs of the reference were to be dealt with by the arbitrator.

The Naming of Streets.—The case of *Collins* v. *Hornsey Urban District Council* was heard last Wednesday in the King's Bench Division of the High Court of Justice. The appellant, Mr. Collins, appealed against a conviction by the justices of Highgate under the Towns Improvement Clauses Act of 1847. The facts of the case were that the appellant was the owner of a building estate on which was a road which he called Midhurst Avenue. The district council, in regard to the approval of plans, had acquiesced in this name being given to the road, but ultimately a Mr. William Arnold, who owned a residence in the locality, which was approached by an avenue of trees and was called Midhurst, took exception to the name. The district council thereon decided that, instead of being called Midhurst Avenue, the place should be called Collingwood Avenue, but Mr. Collins objected. The council, however, put up a board on which the road was described as Collingwood Avenue. The appellant obliterated that description, and for this he was summoned under the Act above mentioned at the Highgate Petty Sessions and convicted. On his behalf reliance was placed on a case decided in the Irish courts, when the Corporation of Dublin proposed to change the name of Sackville Street to O'Connell Street, in which it was held that the Corporation had not the power to do so, and that even if it had the Court was entitled to restrain it if the action would be injurious to the inhabitants of the street. The Lord Chief Justice said that in his judgment the Dublin case was no authority in the case before them, as very different considerations applied to new streets to those which affected existing streets which had long borne a particular name. In this case, though the name of the street which the owner desired should be adopted had been brought to the knowledge of the local authority, it exercised no jurisdiction in the matter until it *bonâ fide* determined that it should be called "Collingwood Avenue." The appellant had no right to do what he had done, and if he had a right to name the street as he liked he should have endeavoured to enforce it by taking proceedings to restrain the respondents. Mr. Justice Lawrance concurred, and the appeal was dismissed, but without costs.

The Black Smoke Nuisance.—At Westminster Police Court last week three summonses for dense black smoke nuisance were heard against the Queen Anne's Residential Mansions Hotel Co., Ltd., Westminster, under Section 24 of the Public Health (London) Act, 1891. For the defence it was said that during the last ten years eight different kinds of smoke-consuming apparatus had been installed, at a cost of about £3,000. Mr. Glen said that the Mansions' chimney took the place of 300 ordinary kitchen chimneys. Mr. Horace Smith, after a long hearing, said he found, as a matter of fact, that on various occasions black smoke issued from the chimney in question in such quantities as to be a nuisance. He also found, as a fact, that defendants had taken all reasonable means to prevent such nuisance. But these efforts he held to be no defence. As a mixed question of law and fact, he found that the chimney was not that of a private dwelling-house. He inflicted a fine of £5 on the first summons, and 10s. each on the second and third. He also allowed £5 5s. costs.

THE RISE OF EGYPT.

BY PROFESSOR FLINDERS PETRIE.

PROFESSOR FLINDERS PETRIE gave the first of a series of three lectures on "The Rise of Civilisation in Egypt" at the Royal Institution on Saturday last. During the last decade, he observed, the whole aspect of the subject had changed. Until 1892 the whole of Upper Egypt was closed—at least to English work. But after that date at the outset British explorers found traces of Mycenæan civilisation—then remains of the dynastic period; and at last we had come to the period of first and second dynasties. These years had been fruitful of results, covering the years from 4000 B.C. to 7000 B.C., and we might say our knowledge of early history in Egypt was now more exact than that of the first ages of any other country in the world. The range covered the unparalleled period of 9,000 years. In a table on the screen Professor Petrie marked successive periods, giving 5800 B.C. as the date of the highest prehistoric civilisation and 7000 B.C. as the rise of that civilisation. The Pyramid builders were about 3600 B.C. The lecturer showed by example the varieties of form and the growth of art and style in successive epochs. The continuity of historic form was already known, and the presence of an alien form led to a reasonable inference of prehistoric character. In pottery a scale of sequence had been worked out with tolerable exactness during the period hitherto regarded as mythical. Then in slate the growth and improvement, followed by decay in workmanship, were shown by pictures of animals which ultimately became excessively formal and constrained. Except with metal the result attained was that art had reached its acme in prehistoric times and then began to degenerate. Figures of colossal size of human and animal forms, cognate with what had been found in South Africa and elsewhere, were discovered, and a connection might be formed by means of these fragments of stone and others of ivory, between Malta, the South of France and Egypt. The age to which these should be assigned was probably the palæolothic. These figures might be regarded as the last remains of the palæolothic period. In the whole prehistoric period there was no trace of the potter's wheel, and the variations of form were greater than was possible to the wheel-formed work. The lecturer next touched on the marks on the pottery—some clearly connected with those of Crete and Libya, and which formed the basis of various alphabets. These signs were traceable throughout the whole history of the Mediterranean until by the growth of commerce and the need for common action a selection had to be made in the form of an alphabet. Thus the links which bound us with the dim past of Egyptian history were more palpable than was generally believed.

Mr. J. E. Lash, architect, of Wrexham, died last week at the age of fifty-one years.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Charges of Surveyors and Others.

Chippenham—N. N. W. writes: "The Kalendar of the R.I.B.A. contains particulars of architects' charges for various kinds of work, which the Institute sanctions. From what sources can reliable information be obtained as to usual charges for the various kinds of profesional work undertaken by solicitors, surveyors, land, estate and house agents, auctioneers and valuers?"

See Hurst's "Architectural Surveyors' Handbook" (4s. nett.) and Evans's "Solicitors' Remuneration Act, 1881" (price 2s. 6d., Sweet & Maxwell), to be obtained from Mr. B. T. Batsford, of 94, High Holborn, W.C.

Liability for Non-Fulfilment of Contract.

Perplexed writes: "A building is erected under the direction of an architect, and the owner employs a clerk of works during the whole time. After about three years some basement floors are taken up, and it is then discovered that only a thickness of 4in. of concrete is laid instead of 6in. as per specification. The owner now calls the attention of the architect and builder to the discrepancy, and declares that he must have the floors taken up and relaid according to specification. This is very unreasonable, as the floors are sound and very good. What are the legal positions of the architect and builder? Are they liable; and how far does the employment of a clerk of works relieve an architect from responsibility?"

It would probably be best to consult a local solicitor, to whom the facts of the case can be explained personally in greater detail. As a general rule, an architect is responsible only for general supervision, and in this instance the owner seems to have specifically acknowledged this by himself appointing the clerk of works instead of leaving the appointment to the architect in the usual course. If anyone is liable for negligence it is the clerk of works; while, if an action were brought by the owner against the builder, he might recover the difference in value between the concrete as laid and that specified. Even this is doubtful, as many judges would hold that the matter was settled when the architect gave his certificate of satisfactory final completion, especially if he was made sole arbiter under the conditions. Had the fault been discovered before this certificate was given, the architect (not the owner) could have ordered the floor to be taken up and relaid of the proper thickness; but unless fraud and collusion between builder and architect can be proved, such a course appears now to be barred. G. A. T. M.

Proportions for Concrete Mantel.

Yorks.—J. T. writes: "What proportions of cement, sand and stone are suitable for making a concrete mantel for a 4ft. opening; size of mantel 5ft. 6in. by 12in. by 8in.?"

The proportions vary according to the class of Portland cement to be used, but for a standard cement use two parts for five parts of aggregate. The aggregate may consist of broken stone, bricks, granite, slag or similar hard materials. Gravel or shingle, being of a smooth and round form, should not be used for this class of work, as they have not the same keying powers as the above-mentioned materials, which are angular and rough when broken. Use neat cement, termed "slip," for the surface coat of the mould, then follow on with the coarse gauge. If the work is done *in situ* use the "slip" for the finishing coat. WILLIAM MILLAR.

Position of Building Surveyor as Architect.

An Old Reader writes: "A building surveyor is an architect practising in one district and resident in a neighbouring town. Is this in accordance with the Local Government by-laws? His salary amounts to £10 a year, and he is a F.R.I.B.A. What is your opinion of this gentleman occupying such a paltry position? Is Is it proper that he should recommend his own plans to be passed by the Board?"

Appointments of this nature are made by the local authority, and are subject to the approval of the Local Government Board, who may interfere if they think the salary excessive or insufficient, the conditions of the appointment unsatisfactory, or the gentleman appointed incompetent. There are many districts where £10 per annum is an adequate salary, there being little or no work to do, and if a competent architect can be persuaded to undertake the duties of the position, it is distinctly to the advantage of the community that he should be allowed to do so, even though it may involve his having occasionally to adjudicate on his own plans. Fortunately architects of position are almost invariably honourable men, so that abuses, though not entirely unknown, very rarely arise in consequence. G. A. T. M.

Concrete Steps.

Sheffield.—F. S. writes: "Please state whether lime, plaster, or cement is best for finishing the backs of concrete stairs. Which is the best way of rendering concrete steps non-slippery? Are there any patent methods employed for this purpose?"

The backs of concrete stairs should be finished with the same materials as used for facing the rough concrete, so that the whole will have a uniform colour and stone-like appearance. For a fine smooth finish, or where the work has to be painted, Portland cement, with the addition of a fifth part of well-matured lime putty, laid and well trowelled, makes sound and satisfactory work. The finishing coat should be laid while the rough concrete is green. Lead, brass, cork, and wood cubes, or studs, embedded in the treads of concrete steps have been the subject of recent patents, but some are similar to previous patents and methods. Merryweather, of fire-engine fame, obtained a patent for the use of lead cubes inserted in concrete to render the saurfce non-slippery; but lead and simliar materials in concrete paving to give a good foothold were used in London about thirty years ago, notably by Allan, who first introduced concrete steps, and also by Lascelles. Indenting by metal or wood stamps, or by brass rollers, or grooving the surface, has only a temporary effect, as continuous or heavy traffic sooner or later effaces the indentations. Another objection is the retention of dust and wet in the indentations. An effectual and novel method of rendering concrete step-treads non-slippery is by the use of rubber plugs in the form of screws, which are inserted at intervals in the concrete surface. By this ingenious method the rubber plugs, after wearing below the surface, can be raised flush with the surface again by simply screwing them up. This process is repeated as required until the plugs are entirely worn away. After this they are speedily and cheaply replaced by screwing in new plugs. The rubber plugs, besides affording a non-slippery tread, also ensure an almost noiseless traffic, and the treads are pleasing in appearance and pleasant to walk upon. Messrs. Burness & Son, plasterers and cementers, Montrose, are the inventors of the rubber screw-plugs. WILLIAM MILLAR.

Sun Prints.

Littlehampton.—Beric writes: "Where can I obtain sensitised paper for photographic sun prints of drawings, &c.; and how is this paper manipulated?"

Paper for sun prints is obtainable at any good dealer in photographic apparatus. All kinds can be purchased from Messrs. Otto König & Co., 27, Cross Street, Finsbury Pavement, E.C.; Mr. A. G. Thornton, 87, St. Mary Street, Manchester; Messrs. J. R. Gotz & Co., 215, Shaftesbury Avenue, W.; or Messrs. Allott, Jones & Co., Bixteth Street, Liverpool. On p. 128 of our issue for March 28th, 1900, we published a review of a book on this subject entitled "Ferric and Heliographic Processes" (Dawbarn & Ward, Ltd., 6, Farringdon Avenue, E.C., price 2s. nett). Some particulars of the different papers and their manipulation are given in this review, but if querist desires full details of the various processes he should obtain the book itself.

Surveyors' Institution Examinations.

Goole.—Surveyor writes: "Kindly give a list of text-books for the P.A.S.I. degree of the Surveyors' Institution (Part III., Building Section) which you would recommend for a student. The Institution syllabus names several, but the difficulty is to select the best for each subject. Would an assistant of several years' service be exempt from the preliminary plans of measured buildings required, and the survey of building plots? If not, would carefully-drawn copies of plans of modern design representing his own *bonâ-fide* design and working-out in the office satisfy the Examiners?"

Usill's "Practical Surveying" (6s.), Middleton's "Surveying and Surveying Instruments" (3s. 9d.), Leaning's "Quantity Surveying" (12s.), Leaning's "Specifications" (18s. nett.), Wright's ' Fixtures" (5s. nett.), Bullen's "Dilapidations" (5s. 6d.). Gale "On Easements," Hudson's "Law of Light and Air," Rivington's "Notes on Building Construction," four vols, Hull's "Building and Ornamental Stones" (7s. 6d. nett.), and Burnell's "Limes, Cements, Mortars, Concretes, Mastics, &c." (1s. 6d.). These can be obtained from Mr. B. T. Batsford, of 94, High Holborn, W.C. With regard to exemption from any subject, you had better write to the Secretary of the Institution, 12, Great George Street, S.W. The drawings need not be highly finished. Ordinary working drawings are quite suitable.

Powers of District Surveyor.

Salisbury.—J. H. writes: "What are the powers of a rural district surveyor and sanitary inspector? A rural district council has no by-laws to guide anyone, and their surveyor is making himself too important."

The district surveyor has no powers other than those conveyed by the by-laws; he is the servant of the local council, and merely acts for it, which is the final authority upon the matter. It is, however, upon his report that it would decide to prosecute if the by-laws are contravened.

The Use of Tufa in Buildings.

London, S.E.—H. C. S. writes: "I have been informed that the use of 'tufa' in a building denotes that the latter is of great antiquity. Is there any authority for this, and if so what period (approximately) does it denote?"

Tufa, or tuff, is a rock composed of volcanic ashes and sand; thus the words are used as general terms to include all the fine kinds of volcanic detritus, ranging from coarse gravelly deposits to conglomerates, and even to exceedingly compact fine-grained rocks formed of the finest and most impalpable kind of volcanic dust. Some tuffs have been consolidated under water, others on dry land, and, as a rule, are distinctly stratified. Rome is practically built upon tufa rock, which will therefore be found largely used in the buildings of that city. Wherever tufa is obtainable, it is but natural that it should be used for building. The fact of its use therefore is no criterion of the age of the building. It is, however, a feature of Rome and Pompeii that the earlier buildings were more generally of tufa than the later buildings, which fashion and wealth had stipulated should show a fine stone face. Tufa does not, as a rule, weather well, and is therefore stuccoed or faced with stones which do. It should be remembered that in early civilisation the materials close at hand would be used until means of transport were evolved.

Books on Hospitals.

London, S.W.—C. F. H. writes: "What is the latest book on isolation-hospital planning and construction, and where can I obtain it?"

"Hospitals for Infectious Diseases," by Sir Richard Thorne-Thorne (5s. nett), and "Healthy Hospitals," by Sir Douglas Galton (8s. 6d.), are books that will be found useful. They can be obtainable from Mr. B. T Batsford, of 94, High Holborn, W.C. Articles on "Hospitals," by Mr. Frederick Batchelor, appeared in our issues for April 7th and 14th, 1897; "Modern Hospitals," by Mr. William Henman, in our issue for March 21st, 1900; and "The Construction of Hospitals for Consumption and other Infectious Diseases," by Dr. John W. Hayward, in our issues for November 23rd and 30th and December 7th, 1898.

Initials in Door Head.

Burton-on-Trent.—H. R. N. writes: "I enclose photographs (not reproduced) of an old doorway of a house (formerly a hall, but now a farm) near here. Kindly state what the letters are contained in the monogram. I have failed to decipher them."

The initials are B, M, C, D, E, but in what order they should be arranged we cannot tell. A crown surmounts them. We should infer they are connected with the family to whom the house first belonged, and we advise that the date of the house be obtained and the records searched for some name or names corresponding to the above initials.

Apportioned Cost of Repairs to Adjoining Drains.

London, S.E.—A. H. writes: "The drain in the next house to mine has been condemned by the sanitary inspector, and the owner is ordered (magistrate's order) to take up and relay it. My house drain runs into this drain. My next-door neighbour says that the alteration of his drain will cost him £18, and that I am liable for half of this sum, because my drain runs into his. I am under the impression that I have to pay for all alterations to drains on my premises, and that he has to pay for alterations to drains on his premises, although my drains run into his. Is this so?"

If the drain in question is a "combined private drain," and not a "sewer" vested in the local sanitary authority, then the cost of reconstructing or repairing the combined drain should be kept quite distinct from other work, and divided equally between the owners of the two houses draining into it. Each house-owner should, however, bear the cost of reconstructing or repairing their own branch drains from their respective houses to the junction with the combined drain. T. E. C.

Fall for Drains.

Bolton.—J. T. writes: "Kindly state the smallest falls for drain pipes of 4in., 6in. and 9in. diameter. Mr. Baldwin Latham gives the minimum inclination for a 4in. drain pipe as 1 in 92; 6in., 1 in 106; and 9in., 1 in 206. Would this be of use to refer to for house drainage?"

The inclinations should never be less than 1 in 62 for a circular pipe 4in. in diameter, 1 in 107 for a 6in. pipe, or 1 in 183 for a 9in. pipe, but greater falls than those given are advisable for ordinary house drainage—say, 1 in 30 to 1 in 40 for a 4in., 1 in 40 to 1 in 50 for a 6in, and 1 in 60 for a 9in. There should be some means of flushing the drains where the fall is less than these latter, either by a small flushing-tank or a quickly-discharging bath.

Material for Forming Ceiling.

Brighton.—Roof writes: "It is proposed to turn the waste space under the roof of a house into a large room, and for this purpose it is necessary to line the underside of the rafters with some suitable inexpensive material that shall be fire-resisting, vermin-proof and warm. Lathing and plastering is objected to, as the house is occupied and plastering work causes excessive dust and dirt. Compo-board and Willesden paper are also objected to, as neither quite fulfil the requirements. Asbestos slate would be too expensive. The rafters and collars are the usual 12in. apart."

We would suggest the use of fibrous-plaster slabs, which are cheap, easily fixed, and, when stopped, can be papered; or slabs with finished faces can be obtained, and when stopped are equal to an ordinary plastered surface. If these are objected to, you might use "Uralite," a fireproof and non-conducting material in thin sheets, or "Salamander" fireproof ceiling decorations in relief. Particulars of these latter materials can be obtained from The British Uralite Co., Ltd., at 37, Lombard Street, E.C., and the Wall-Paper Manufacturers, Ltd., 158 & 160 Charing Cross Road, W.C., respectively.

Sewer Pipes.

Yeovil.—R. S. K. writes: "What is the best material for sewage pipes of 30in. diameter? Why are not such large pipes made in ordinary stoneware? What is nalethric stoneware; and does this latter make a good sound pipe for the above purpose?"

Concrete pipes have been largely used when required of large size. Ordinary stoneware pipes are liable to crack and warp in the firing, and would be extremely difficult to make to this size. "Nalethric" stoneware is made from a special heavy fireclay worked by Messrs. Oates & Green, of Halifax; extremely good sanitary tubes are made by them of this ware.

Sewage Treatment.

Wellington.—Outfall writes: "I should be glad to know where the bacterial treatment of sewage is carried out on the following lines: With two series of beds, the first filled with rough material with upward continuous flow and having a rest of a week or so, say, once a month; the other filled with fine material having downward flow and the usual times for filling, standing full, emptying, and resting, as adopted by Mr. Dibdin. There would be a sedimentation tank, holding at least one day's flow before entering the beds."

We do not know that the system referred to is worked anywhere, but in all probability it has been tried. The nearest approach to it is the Scott-Moncrieff system, in which the sewage passes up through a false bottom, rises between successive strata of flint, coke and gravel, and flows at its original level (or thereabouts) on to a thin layer of filtering material on a tray, then falls a few inches and encounters similar layers. This system is adopted at Caterham and works very satisfactorily. The short paper on the bacterial treatment of sewage in our issue for February 21st, 1900, summarises the system. If you construct beds on the system proposed we should certainly advise a sedimentation tank. The beds if worked with a sedimentation tank would not require a rest so often as once a month.

Laying of Purlins on Rafters.

Portmadoc.—Student writes: "Kindly explain which to notch in laying purlins on principal rafters, and give the reason for notching one more than the other. What is your opinion of Burrell's Building Construction (Elementary Course)?"

The purlins are always notched, and not the principal rafters. The reason for this is to keep the principals firm, and although it is of course possible to devise some other method of fixing them it would be of no particular advantage, and would be likely to weaken them more than the usual method. To notch the principals would be distinctly unscientific and to no purpose, as they would then be free to overturn. There is also the question of economy to be considered; small timbers are more abundant and more easily obtained than large ones, and therefore it is preferable to increase the size of the purlins to allow for the weakening by the cutting than to increase the size of the principal rafters for that purpose. Burrell's Building Construction is a useful little book to use to study in preparation for the South Kensington Examinations, but of course is not so useful a guide to practical work as the larger works.

Books on Timber.

V. W. sends the following further reply to the query of "Renuad d'Est" (see p. 244 of our issue for May 1st last): "Wood and its Use as a Constructive Material,' by W. Stevenson (published by Mr. B. T. Batsford, 94, High Holborn), is a most excellent work, full of most valuable information. The author is a timber merchant, of Hull and Scarborough, a traveller in the chief wood-growing countries, and one who takes an enthusiastic interest in the material he deals in beyond its mere buying and selling. He is a frequent contributor to the timber trade journals and the architectural periodicals."

R.I.B.A Examinations.

Aberavon.—Libro writes: "I am desirous of entering for the R.I.B.A. examinations. I have passed the London Matriculation in the first division, and hold the senior certificate of the Central Welsh Board. In addition to this I have certificates (elementary) in the Science and Art Department for model drawing, freehand drawing and geometrical drawing. Do these give me full exemption from the first examination, and if so how can I get a certificate to prove this when I take the next examination?"

The London Matriculation exempts you from examination in Subjects 1, 2, 3, 4, 5 and 7 in the R.I.B.A. Preliminary, but to be exempted in Subject 6 you need to hold first-class certificates in the elementary Science and Art Examinations in both Geometrical Drawing, Subject 1*a*, and Perspective, Subject 1*c*), and to be exempted from Subject 8 you need to hold a first-class certificate in the advanced stage Science and Art Examination for outline drawing of ornament from the cast (Subject 3*b*). Full particulars can be obtained from the Secretary, R.I.B.A., 9, Conduit Street, Hanover Square, W.

Halifax.—F. O. writes: "Kindly give me a list of text-books (exclusive of larger reference books) which one should obtain for preparation for the R.I.B.A. Intermediate examination."

A list of suitable books is to be found in the R.I.B.A. Kalendar, obtainable from the Secretary, 9, Conduit Street, W., price 2s. 6d.

Cracked Plasterwork.

Preston.—Ribble writes: "The flue from the heating apparatus of a chapel passes through the vestry. The flue is of 4½in. brickwork, plastered and painted. The plaster is full of unsightly cracks, due, I suppose, to the heat of the flue. Do you know of any cure for these cracks?"

The plastering has in all probability been badly done, either as regards materials or workmanship, or both, although the heat of the flue would also have something to do with the cracks. Cracks may be ascribed to any one or several of the following causes: too quick drying, considerable variations in temperature just after the plaster is put on, the laying of one coat of mortar on another, too strong a suction of the backing due to dryness, thus absorbing all the moisture from the plaster and causing it to shrink and become crumbly; use of bad materials, and bad workmanship. The brickwork of the flue is also not thick enough; for if the heat is considerable the bricks will expand, and this with the subsequent contraction is productive of cracks. Plaster and sand resists heat well. There would appear to be no adequate cure if the heat is great, except to build a new flue and replaster.

Sand for Plastering.

Mansfield.—En Avant writes: "Which is the best sand to use for coloured setting for internal plastering; also for Portland cement for exterior work?"

A good gritty silicious sand should be used, free from loam or muddy particles, as these are detrimental to the setting. Obtain samples of the sands you have handy, and shake them up with water. If the water is much discoloured after the vessel has been kept still for several seconds, the sand is not suitable. Silver sand being fine grained gives a good internal finish, but the calcareous kinds are bad. For external work a larger grained sand can be used.

Sewer.

Taunton.—One in Doubt writes: "Would a circular brick sewer 24in. diameter, 6,500ft. in length, having a total fall of 15ft., or 1 in 433·33, with a minimum flow of 180 gals. per minute, be self-cleansing, and if so what would be the velocity? Also what would be the least safe fall for the efficient working of such a sewer? Is the same velocity maintained with the same rate of fall, no matter what the length?"

The sewer would not be perfectly self-cleansing, but would require, as most sewers do, to be periodically flushed in parts. The velocity with the minimum flow of 180 gals. would be about 1·8ft. per second, and when full about 2·88ft. per second. The discharge running full would be about 4,000 gals. per minute. Sewers, to be self-cleansing, should have a mean velocity of flow of not less than, 2½ft. per second; however, the velocity need not be so high to be quite efficient enough, but the velocity should never be less than 1ft. per second at any time nor more than 4½ft. per second; beyond the latter the bed would be worn away. The least fall advisable for the sewer mentioned would be 1 in 577.

Our New Insurance Schemes are summarised on page 290 of this issue.

Keystones.

A Swimming-Bath for Women.—The Local Government Board has sanctioned the borrowing by the Reading Town Council of £4,500 for the erection of a ladies' swimming-bath.

County Offices at Newport, Mon.—A Local Government Board enquiry was held recently into an application by the Monmouthshire County Council for permission to borrow the sum of £10,000 for the purpose of providing a council chamber and extending the county offices at Pentonville, Newport.

The Wagner Theatre at Munich.—The new Prince Regent Theatre, or Richard Wagner festival playhouse, in Munich, is now rapidly advancing towards completion. It is being erected on the banks of the River Isar, not far from the spot where King Louis II. of Bavaria intended to build a Wagner theatre. The stage is to be built according to Wagner's ideas of theatre construction, and the scenic arrangements will, it is said, be in advance of anything yet attempted. The auditorium will be in amphitheatre form.

Mr. R. Ll. Jones, Architect and Surveyor, of Carnarvon, died recently at the age of fifty-three years. Deceased served the early years of his career with Mr. R. J. Davids, C.E., who, among other things, carried out the water supply scheme of the town. Subsequently, for a period of twenty-five years Mr. Jones filled the appointment of surveyor to the Carnarvon Corporation. Resigning this, he became a member of that body, but afterwards took up the surveyorship a second time. He retired again some four years ago.

The Foundation Stone of the New Cathedral at Brisbane will be laid by the Duke of Cornwall and York on May 22nd. The site of the building is described as excellent. The desings were drawn up by the late Mr. J. L. Pearson, R.A., and will be carried out by Mr. F. L. Pearson, in conjunction with Mr. W. D. Caröe. The complete design, of which the probable cost would be £100,000, and which would provide 3,000 sittings, will not be carried out at present, for want of funds, but it is proposed to begin with the choir and transepts, to accommodate 1,200 worshippers. This will cost £35,000.

A New Baptist Church at Haslingden, Lancs., has just been opened in Bury Road. It accommodates on the ground floor 328 persons, in the galleries 279, and in the choir 20—total 627, or a mixed congregation of over 700 persons. There are four vestries attached, and also a choir vestry adjoining the organ chamber, which is in the form of a semicircular apse, with the choir in front of the organ and behind the pulpit. The seating is varnished pitch-pine. The gallery fronts are of pitch-pine with carved oak panels, and the pulpit of oak with carved panels. The ceiling is of plaster, curved in the centre, with open timber trusses. The ventilation and heating are on the most approved principles. The walls are of rock-faced stone, with Ashlar stone dressings. The cost has been over £5,250. The architects are Messrs. George Baines, F.R.I.B.A., and Reginald Palmer Baines, 5, Clement's Inn, London. The schools adjoining were erected previously from plans by the same architects.

Worcester Victoria Institute has had a marked success in the recent examinations in building construction at South Kensington, four of its students having gained first classes in Honours, only ten candidates from all parts of the kingdom being placed in the first class. These four students passed through Honours, Part I., during the Session 1898–9, and continued Part II. last year with the success mentioned, thus covering the two stages successfully in two consecutive years' work; they were also the full complement of the class in these stages during the two sessions. Mr. Alfred G. Parker, the youngest of the ten referred to above, was first in order of merit in the whole of the kingdom. Mr. Edward Higgs was fourth, Mr. William J. M. Thomasson sixth, and Mr. J. Pitcher bracketed seventh. The two last-named were, except Mr. Parker, the only students of the ten under twenty-one years old at the time of the examination. The result reflects the highest credit on the students and their instructor in this subject, Mr. Joseph Mottram, himself a First Honours Medallist.

A New Mission Church, in East Twickenham, is to be built on some land to the north of St. Margaret's Railway Station, in connection with the parish of St. Stephen's.

The Max Müller Memorial is to take the form of (*a*) a bust, relief, or portrait in the Bodleian Library, and (*b*) a fund to be called the "Max Müller Memorial Fund," which may be held by Oxford University in trust for the promotion of learning and research in all matters relating to the history and archæology, the languages, literatures and religions of ancient India.

The Royal Institute of Architects of Ireland held a meeting on May 2nd, when the following resolution, proposed by Mr. J. J. O'Callaghan and seconded by Mr. F. Franklin, was carried unanimously: "That the draft by-laws of the Ulster Society of Architects be approved of, and that the Council of this Institute be authorised to make the necessary alterations in the by-laws of the Institute to make them conform with those of the Ulster Society." The following candidates for membership were declared duly elected—Messrs. William A. Scott, London; Jerome O'Connell, Curragh Camp; Henry Seaver, Belfast; and Anthony Thomas Jackson, Belfast.

A New Parish Church at Insch is being erected on the south side of the Western Road, almost immediately opposite the church. It is being built of granite, with freestone dressings. The gable will abut on the street. The main entrance will be sheltered by a porch, and will lead into the hall, which measures 26ft. by 40ft. Behind this hall there will be a guild room 15ft. by 21ft., a classroom 14½ft. by 8ft., a kitchen, and other conveniences. The estimated cost of the undertaking is £592, without the surrounding walls and furnishings. The architects are Messrs. James Duncan & Son, Turriff; and the contractors Mr. F. Manson, builder, Insch: Mr. Thomas G. Archibald, carpenter, Huntly; Messrs. William Milne & Son, slaters, Huntly; Messrs. Seivwright, plasterers, Inverurie; Mr. Robert Douglas, plumber, Huntly; and Messrs. Sutherland & Son, painters, Inverurie.

New Bank Premises, at Littlehampton, are being erected for the Capital and Counties Bank in the Beach Road. A stone porch looking west, and facing the High Street, forms the entrance. The building will be of red brick relieved on the ground floor with stone for the porch and bays. On the first floor the facings will be picked out with stock filling and red brick quoins, while the roof will be of green slates; the eaves being of wood, painted white, and surmounted by two pediments, with carved coats of arms. The inside accommodation should be ample for all local calls, the general office and public space measuring 31ft. 6in. by 23ft. 3in., and having at the rear a two-storey strong room fitted with lift. The estimated cost is between £4,000 and £5,000, and the work is being carried out by Messrs. James Linfield & Son, builders, of Littlehampton; Mr. G. H. Hunt, F.R.I.B.A., of Bedford Row, London, W.C., being the architect.

St. Matthew's Established Church, Morningside, Edinburgh, has been extended by the addition of a chancel. A memorial stained-glass window has also been added. The scheme for the provision of a chancel and an organ has cost £2,236. The chancel is of rectangular shape, externally simple in design and in harmony with the rest of the building. The roof is vaulted in timber, the walls panelled in oak, and the floor laid with richly-coloured marble. In the east gable is the window of four lancet lights, comprised within a moulded pointed arch, the upper part of which is treated with cusp vesica and quatrefoil openings. The figures and scenes, with one exception, were designed by Sir Edward Burne-Jones, and the work was executed by Messrs. Morris & Co., of Merton Abbey, Surrey. The vesica in the upper portion of the window shows our Lord in Glory, with hand upraised in benediction. Two small medallions contain a representation of works of Mercy. In the principal lights are portrayed the four Evangelists with their respective emblems—the winged man or angel being attached to St. Matthew, the lion to St. Mark, the ox to St. Luke, and the eagle to St. John. Below the figures of the Evangelists are depicted four scenes more or less characteristic of each Gospel.

New Council Chambers and Fire Station at Burton Latimer have been opened. Mr. J. Boardman was the architect.

Public Baths for Elland are being erected at a cost of £6,000 on South House Estate, adjoining the District Council Offices. The baths are to be Elland's memorial to the late Queen Victoria's Diamond Jubilee.

A Memorial to the Author of "Lorna Doone" is to be erected in Exeter Cathedral, and Mr. Harry Hems, of Exeter, has, at the suggestion of Mr. Blackmore's representatives, been selected to carry out the work.

Home Arts and Industries.—The Queen has graciously signified the continuance of Her Majesty's patronage to the Annual Exhibition of the Home Arts and Industries Association at the Royal Albert Hall. The exhibition will open on Thursday next.

A New Town Hall at Paddington is proposed to be erected to comprise municipal offices and halls for public entertainments, on the site of the existing inadequate Paddington Town Hall, Harrow Road, and land adjoining. Designs for the new building are to be invited.

Proposed Baths at Swinton.—A Local Government Board enquiry was held recently into an application of the local authority for sanction to borrow £6,880 for the erection of public baths and the purchase of land; £5,062 for private street improvements, and £4,247 for pleasure grounds and public walks at Newton, the amount asked for altogether being a little over £16,000.

A Monument to Mr. G. W. Johnstone, R.S.A., the landscape painter, is proposed to be erected in Morningside Cemetery, Edinburgh, where he is buried. The committee includes Messrs. Hippolyte J. Blanc, Robert Gibb, W. D. Mackay and J. Lawton Wingate, all Scottish Academicians, and the secretary is Mr. J. C. Strettell Miller, W.S., 38, Greenhill Gardens, Edinburgh.

The Agitation about the Decoration of St. Paul's is on the eve of breaking out afresh. Sir William Richmond has completed for the Whispering Gallery a design which will gradually extend itself over the dome. Various architects are stated to have approached Sir William in the friendliest way asking if they may look and speak. In one case he seemed to half promise a consultation, which has, however, never come off.

Masters and Men.

The Swansea Painters, Masons and Labourers have struck for a ½d. increase of wages and alterations of working rules.

The Merthyr Tydfil Stonemasons have struck for an advance from 8d. to 8½d. per hour and a new code of rules.

The Tyldesley House and Ship Painters' Society has secured for its members a rise in wages of ½d. per hour.

A Strike at Bolton has occurred of the plumbers, slaters and slaters' labourers for an advance in wages and an alteration of winter hours. About 300 are idle.

The Plasterers' Strike at Barnsley for an advance of wages to make the pay 9d. per hour, and for alterations in the working rules, has been settled, the men being accorded the advance they asked for, and their working hours reduced to 49½ per week.

A Strike at Leigh and Atherton has occurred of about one hundred men employed in the building trade for a wages advance and improved conditions of labour. The plasterers ask for an advance of from 9d. to 10d. per hour and alterations of working rules, and the painters desire an increase of from 8d. to 8½d. per hour and similar alterations of rule. About seventy men are affected.

The Gosport Bricklayers and Labourers have been granted an increase in wages. The wages for fully qualified workmen will be 8½d. per hour, and for labourers 5½d. per hour. The general working conditions will be the same as heretofore. This means that only bricklayers who know their work will be in a position to claim the additional halfpenny, and that the less skilled men with the trowel will have to carry on under the old conditions.

New Patents.

These patents are open to opposition until June 17th.

1900.—Concrete Piles.—4,548. G. L. MOUCHEL, 124, Holborn, London, W.C. This invention relates to hollow concrete piles. To prevent buckling, a series of struts and diaphragms are arranged internally. The head of the pile is made solid with concrete alone, or in combination with metal. The chief advantages of the invention are that the metal skeleton is completely wrapped in concrete, and so preserved, and the pile is more cheaply made than one wholly of metal.

Concrete Floors, &c. — 9.808. L. DE VALLIÈRE, Lausanne, Switzerland. Round iron bars are combined with flattened coils of wire having the lower portion of their windings passing underneath the bars, the upper portion being buried in that portion of the concrete which is subjected to compression.

Imitation Marble. — 15,830. J. TUCKWELL, 180A, Hope Street, Glasgow. To a mixture of one part each of Keen's marble cement and fine white silver-sand is added ground alum in the proportion of about 1 part to 200 parts of the mixture. Sufficient water is used to form a paste, which is then moulded as desired. The surface may be coated with enamel or painted and then stoved, being afterwards polished, first with rotten-stone and water, and then with a composition of beeswax, turpentine and precipitated chalk.

Wooden Planks.—19,901. J. RATCLIFFE, 181, Denton Lane, Hollinwood, Oldham. Instead of discarding planks because of knots in them, these latter are removed, a true hole is bored and then filled with a screwed wooden plug, which is planed level with the surface.

Parquet Floors.—21,950. F. BOSSHARDT, 4, Corporation Street, Manchester (communicated by the *Société Anonyme Parqueterie Franco-Hongroise*, of Jumet, Belgium). The floor consists of strips of wood (preferably oak) laid on a basis of cement of the same thickness as the strips. Dovetail projections are provided to secure a firm hold.

Flat Roofs.—22.823. H. R. VAUGHAN, Ash Grove, Stranmills Road, Belfast, and the PATENT VULCANITE ROOFING & ASPHALT CO., LTD., Laganvale, Belfast. Wood trellis girders are constructed with double lower chord-pieces and bow-shaped ribs enclosing wood trellises, forming struts, which are continued above the bows to a double upper chord. On top are joists and boarding covered with impregnated felt fastened with "Vulcanite" composition, a covering of sand and gravel being also provided. Unobstructed space from floor to roof is thus obtained.

The following specifications were published on Saturday last, and are open to opposition until June 24th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—5,791, HOW & KING, fasteners for fanlights and ventilating hoppers. 7,219, BALDRY, devices for rendering cranes applicable as excavators. 7,751, SEAGRAVE, apparatus for generating acetylene gas. 7,859, JOHNSON (*Compagnie Francaise de l'Acetyléne Dissous*), means for generating acetylene gas and for lighting by such gas. 7,884, PULLON (partly by *Van Blarcon*), filter applicable for use in sewage treatment. 8,548, RYDILL, couplings or unions for taps, pipes, &c. 8,820, BLUNDSTONE, method of producing white lead. 8,849, THURMAN & SMITH, pulleys and pulley stiles for windows. 9,063, NIXON, screw-down taps and valves. 9,854, WOLFF, foot bridges. 9,870, SWAIT, covers for street gulleys, &c. 10,680, SWIERS, means for automatically fastening gates 10,865, SOHEGÉ, composition for tiles, roofing, &c. 10,895, EWING, joints of stoneware and other pipes. 10,900, HOWARD (*Cormack*), air coolers and refrigerators. 10,952, ALLEY, stop valves. 10,975, MILNES, steps or treads. 11,048, GRISSON, hoists, winches, &c. 11,084, TWYFORD, urinals. 11,087, TWYFORD, fittings for surgical and other sinks, water-closets, &c. 11,146, TWYFORD, cantilever and other brackets for supporting flushing cisterns, lavatories, &c. 11,542, KEAY, pavement lights. 12,176, BRODIE & PRIOR, fire-grates. 12,307, BERESFORD, water-closets for railway carriages. 12,340, REBOUL, smoke-consuming apparatus. 18,903, TATTERSALL, emery-grinding machines. 19,288, GREEN, portable apparatus for hoisting heavy lamp columns, pillars, &c., into place.

1901.—1,479, LAKE (*D. Wachtel & Co.*), production of slaked lime. 3,186, TUCKER & WHITE, apparatus for testing house drains. 3,282, BROMHEAD (*Möller & Pfeiffer*), manufacture of solid blocks of cement out of cement slush. 3,290, HARCOURT, indicator latch for closet doors. 4,954, COOK & HEUSNER, acetylene-gas machines and regulators. 5,346, LATHBURY & SPACKMAN, apparatus for calcining cement. 5,373, ADAMS, siphon cisterns.

BAWTRY CHURCH.

THE reopening of Bawtry Parish Church after restoration took place recently. The restoration has been carried out under the superintendence of Mr. Hodgson Fowler, F.S.A., of Durham, at a cost of £2,800. The extensive alterations include the cleaning of the beams of the nave and the chancel roof, and panelling under the rafters; renewing the aisles, roofs, and externally recasting the old lead and relaying it; the insertion of five clerestory windows on the north wall, both for the sake of light and ventilation; cleaning all the dressed stonework of the walls from colour wash, and re-plastering them, taking up the floors and laying a 6in. bed of concrete under solid wood floors. The old high pews have been entirely removed from the body of the church, and have been utilised as panelling in the vestry; the pews are replaced with open deal seats, which have been polished a dark green; oak seats and other fittings of oak have been supplied for the chancel. Other alterations and renovations include trenching the building outside as a preventative against further damp, the removal of the organ—which has been thoroughly cleaned and repaired—a few feet, thus providing a vestry, replacing the present staircase to the ringing chamber by a new one, removal of the gallery from the west arch, and providing a new heating apparatus. A new lighting arrangement has also been carried out. It is desired to have a screen for the separation of the chancel from the nave, and also screens for the aisles, but these matters have been deferred for the present owing to want of funds. The repairing of the chancel has been undertaken by the Master and Fellows of Trinity College, Cambridge, the patrons of the living.

REALITY IN RELIGIOUS ART.

THE half-yearly general meeting of the Church Crafts League was held last week at the Vale Studio, Chelsea (kindly lent for the occasion by Mr. T. Stirling-Lee), the Bishop of Rochester being in the chair when a discussion took place on the subject of "The importance of Reality in Art and Religion." Canon Scott Holland, the first speaker, said that it was important to remember that individuality in art was not, a mere eccentric detachment from the spirit of the time, but was the embodiment of the feeling of the great corporate body. In the matter of church music much had been said by expert musicians as to the folly of having a precentor to direct the music in churches where the organist was a competent artist. But it was not as if the art was standing alone. It was called in to *assist* the worshippers, and therefore the precentor was for the time being the expert. The same principle applied to all other branches of Art, and it was just this that distinguished religious art from secular. Mr. Henry Holiday dealt at length with the conditions under which the modern journeyman had to live and work. It was impossible, he said, for a man to take any intelligent interest in, or to put his heart into, his work now, because the conditions of modern commercial life had converted him into a mere machine. Rev. Percy Dearmer said that when one looked at the homes of the people, one saw an utter absence of beauty—everything was shoddy and cheap. When one looked at the churches, one found much the same thing. Most of the fittings were made to look as if they had cost twice their real price. There was an entire absence of that reserve which goes so far towards making a thing beautiful. If the decorations of a church were so vulgar and bad that one's nerves were so affected that it was impossible to worship, one was considered affected if one said so. But if the music at a church was noisy and vulgar and in bad taste, one was considered to have a very plausible reason for staying away. Mr. Halsey Ricardo said that art was a man's message to his fellow-men. Every artist had to learn all that his predecessors had learnt, and then go on beyond them. Thus Mozart in one age learnt all that could then be learned about music, and built up his own work on that. Beethoven in another age had gone beyond all his predecessors, and, still later, Wagner had done the same. Miss Lowndes, Mr. T. Stirling Lee and the Rev. A. W. Hutton also spoke. In summing up, the Bishop of Rochester warned his hearers against the danger of hopelessness in thinking of the Church's attitude to art.

Builders' Notes.

Mr. James M'Kenzie, joiner and builder, of Longside Village, Aberdeen, died recently at the age of seventy-eight years.

Mr. Thomas John Penton, of Conheath, Richmond Park, Bournemouth, died recently at the age of fifty-one years. Deceased was a member of the firm of Bath and Penton, builders and contractors, of Bournemouth.

Ex-Bailie Jaffrey, of Johnstone, died recently at the age of fifty-three years of age. Deceased was the senior partner of William Jaffrey & Sons, builders, and was connected with the erection of many of the prominent buildings in the town and district.

British Fire Prevention Committee.—Owing to the serious indisposition of Edwin O. Sachs, chairman of the committee, the formal opening of the new testing station at Westbourne Park will be postponed to the end of the month; but the first private test took place last week under the direction of Mr. Ellis Marsland.

London County Council.—At last week's meeting the annual estimates for the ensuing financial year were discussed. Last year an expenditure of £3,996,737, was estimated for, while the actual expenditure was £3,927,352, or £69,385 less than the estimate. For 1901–2 they estimated for a total expenditure of £4,215,395, and a revenue of £4,168,771. In 1889 the Council inherited from the Metropolitan Board of Works a debt of £28,373,729, although certain assets taken over reduced the nett debt to £16,867,909. To this needs to be added debts taken over from Middlesex, Kent and Surrey, so that the Council commenced its career twelve years ago with a nett debt of £17,563,262. During these twelve years they have provided a sinking fund of £7,257,616. On the other hand, they have considerably increased the indebtedness by the issue of stock to defray their own expenditure on street improvements, new drainage, fire brigade, housing schemes, tramways, and other permanent works, and for the purpose of lending money to other local bodies. The nett debt on March 31st was £24,813,694, an increase of £7,250,432. Of this £2,491,520 represents debt incurred on tramways and working-class dwellings, which involved no charge on the rates whatever. Therefore the additional dead-weight of debt incurred by the Council during its administration was £4,758,912. Against that increase, however, is to be set the growth of the ratable value of London, £8,192,000.

A Keighley Competition.—Mr. Leonard Stokes, F.R.I.B.A., has been appointed to adjudicate the 146 designs received by the Keighley Corporation for the proposed free library. The total value of the plans probably amounts to about £5,000.

Surveying and Sanitary Notes.

Messrs. J. M. Klenck & Co., auctioneers, surveyors, valuers, &c., owing to the increase of their business, have removed from 64, Bishopsgate Street Within, E.C., to more suitable offices at No. 72 in the same street.

Paving at Dewsbury.—The Local Government Board have sanctioned power to the Corporation to borrow £4,733 for granite paving of Huddersfield Road and Thornhill Road, Dewsbury; £417 having been deducted in respect of value of outstanding loan in respect of Huddersfield Road.

Lowe's Patent Sanitary Pipe Joint Syndicate, Ltd., of Dashwood House, New Broad Street, E.C., have recently effected an arrangement with Messrs. J. Stiff & Sons, of Lambeth, whereby this well-known firm become their sole agents for London and suburbs. The advantages claimed for this system of drain pipe jointing are that a perfect and reliable water-tight joint is formed as soon as it is made; that a number of pipes can be jointed on the surface of the ground before laying them in the trenches; that the elasticity of the joints gives absolute security against the escape of sewer gas from the joints, which so frequently occurs with other systems of drain pipe jointing; and that the pipes being socketless lie more evenly when laid.

Engineering Notes.

The Thornhill District Hospital, Dumfriesshire, is being warmed and ventilated by means of Shorland's patent Manchester stoves, patent exhaust roof ventilators and special inlet tubes, supplied by Messrs. E. H. Shorland & Brother, of Manchester.

Southport's Water Supply.—The Earl of Jersey's Committee in the House of Lords has passed the preamble of the Bill, promoted by the Corporation of Southport, the Birkdale Rural District Council and the West Lancashire District Council, to authorise the formation of a Joint board representing the three local authorities, and the purchase by such board of the undertaking of the Southport Waterworks Company, which has a capital of no less than £425,000. The Bill was strongly supported locally, its only opponent being the Waterworks Company itself.

The Cause of Tube Vibration.—Lord Rayleigh's Vibration Committee on Underground Railways, in their report to the Joint Parliamentary Committee on Underground Railways, declare that they have satisfied themselves by personal inspection of the fact that "there is serious vibration to be felt in many of the houses situated along the course of the Central London Railway." Observations made by means of self-recording instruments trace the vibration mainly to two causes—the large proportion of the weight of the electric locomotive not borne by springs, and want of rigidity in the rail. The Central London Railway Company has ordered a new type of locomotive from America, and when it has been tried the Committee will report further; but they believe that "on new tubular railways under proper conditions no objectionable amount of vibration need be apprehended."

The Iron and Steel Institute held its annual meeting last week at the Institution of Civil Engineers. The Report of the Council, which was presented, gave the number of members on the roll of the Institute at the end of the year as 1,644. The income for the year was £4,157, and the expenditure £3,771. The officers and council for the year having been appointed, the president-elect, Mr. William Whitwell, delivered his presidential address, in which, glancing at the progress of the past century, he dwelt on the value of research. As to the value of research in the solution of metallurgical problems, and the improvements of our methods of manufacture, there could be no question. In the progress of the past century, certain achievements stood out more prominently than others. Two of the most important were the reduction of waste and the utilisation of waste by products in all manufactures. Though we had advanced so greatly, there were still many problems in our iron and steel industries awaiting solution. In conclusion, Mr. Whitwell touched upon technical education, and asked the question: Were we using that education to the best advantage in our industries, or letting much of it go to waste and the mental abilities of our workers to rust? That was a matter our manufacturers must look to, and make sure that the education given to our workers was not lost or only indifferently used.

LIFE

is so precious and accident so frequent that every Subscriber to the "BUILDERS' JOURNAL" should hasten to avail himself of the advantages of our **Insurance Tickets.** Apply at once for them to

THE MANAGER,
"BUILDERS' JOURNAL,"
Effingham House,
Arundel Street.

There are **Three Schemes of Insurance** connected with our Papers, guaranteed by the OCEAN ACCIDENT AND GUARANTEE CORPORATION, LTD. They are of the greatest importance to our Subscribers.

Scheme No. 1 is a free Accident Insurance of **£500.**

Scheme No. 2 is an Accident Insurance of **£500,** giving the following additional advantages:

£250 for Permanent Total Disablement.

£2 10s. 0d. per week for Temporary Total Disablement.

The premium for this Scheme is 1/-

Scheme No. 3 is an Accident Insurance of **£1,000,** with these additional advantages:

£500 for Permanent Total Disablement.

£6 per week for Temporary Total Disablement.

£1 10s. per week for Temporary Partial Disablement.

£30 Annuity.

£3 per week during confinement from such illnesses as Diabetes, Scarlet Fever, Carbuncle, &c., &c.

The Condition attached to these Schemes is that they only apply to Annual Subscribers to

The Builders' Journal.

The Architectural Review.

If these schemes interest you, write for full particulars to

**THE MANAGER OF THE
BUILDERS' JOURNAL,
EFFINGHAM HOUSE, ARUNDEL ST.,
STRAND, W.C.**

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDERS MAY BE OBTAINED.
	BUILDING:		
May 17	Aberdeen—House	———	A. Taylor, Overseer, Wardhouse.
" 17	Cadoxton-j-Neath, Wales—Vicarage	Rev. J. D. James	G. E. Halliday, Architect, Cardiff.

An Architectural Causerie.

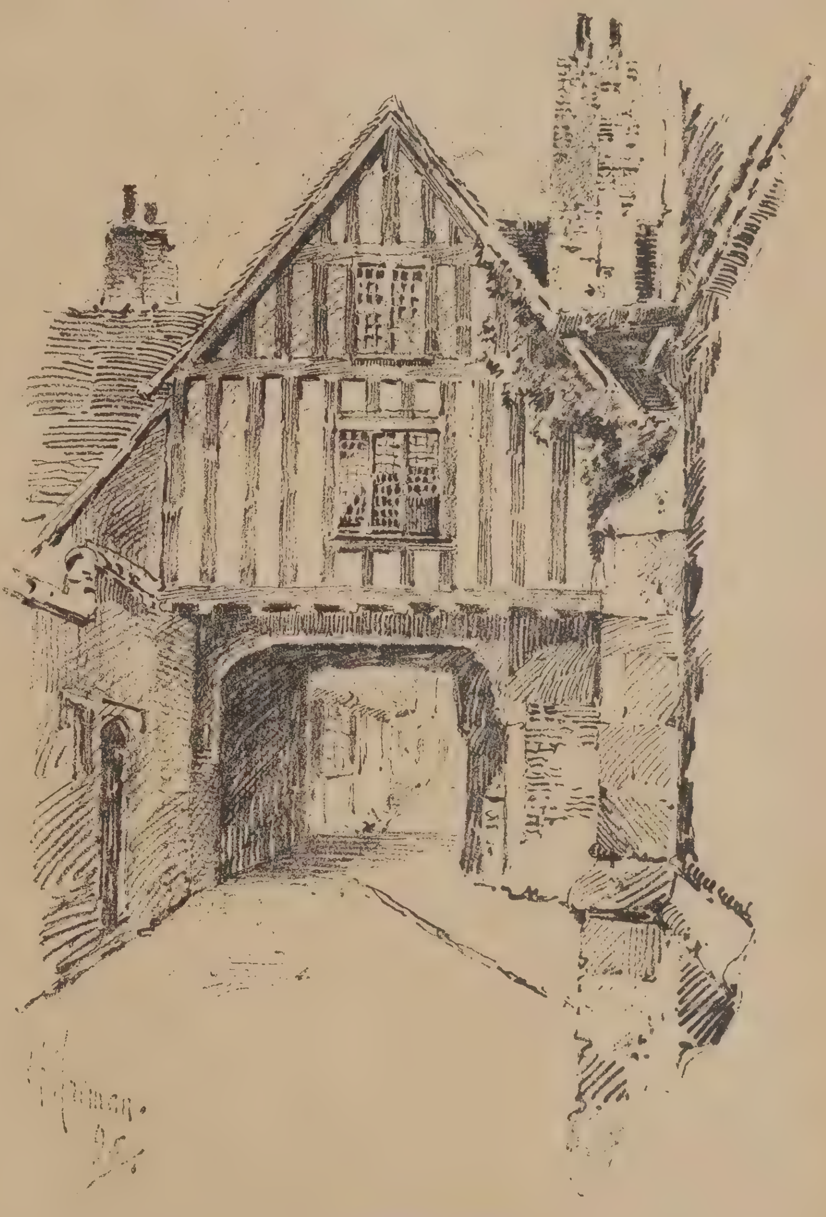
Once More. THE London County Council, in its eagerness to be artistic, is responsible for the new set of florid electric-lamp standards now being erected along the Victoria Embankment. These have been cast by Messrs. Walter Macfarlane & Co., and have an ornate base decorated with ornate fishes possessing ornate tails; while at the top of the shaft there is spiral—design (shall we say) from which the arc lamp will depend. Why will the Council spend money on such things, when so much better are obtainable? It is no more expensive to cast a good design than a bad one. We do not know whether these standards were designed in the Council's offices or in those of Messrs. Macfarlane, but that they are artistically a failure is at once evident by comparing them with those elegant standards by Vulliamy which extend in close proximity along the top of the Embankment wall.

A Half-timbered House. THE sketch of a half-timbered house on this page was made from a photograph by Mr. Herbert Norman as a time study (one hour being allowed) at the sketching class that used to be held in connection with the Birmingham Architectural Association.

The Pyramids. OF all the problems associated with the Egyptians none is more interesting than that summed up in the question, How were the Pyramids built? The land of the lotus is ever a mystery to us, the civilisation of its ancient people an enigma, its colossal ruins awe-inspiring, wondrous and unique in the history of the world. Our knowledge, however, of their aims and achievements is slowly growing in extent and lucidity, thanks to the painstaking investigations of archæologists, scientists and engineers, and we now know for certain that the Egyptians were a most scientific and mechanical people. Nebka, a king who lived nearly six thousand years ago, was "skilled in the art of erecting solid masses of hewn stone," and the practice continued for thousands of years, the passion for building colossal structures being most predominant between B.C. 1600 and 1200. Cheops, in his great pyramid, was content with stones weighing about fifty tons each, but stones twenty times as heavy were used in the two huge statues of Amenhotep III. on the plain of Thebes. Solomon put a 90-ton stone in the outer wall of Temple Hill at Jerusalem 100ft. from the ground, while the portal of the treasury of Atreus is covered by a stone weighing 130 tons. Then, again, coming to later times, we find stones 40ft. long, 10ft. thick, and no one knows how wide, in the castle wall at Osaka in Japan, and even if they are only 10ft. wide they would each weigh 300 tons. It cannot be denied, as Commander Barber says in his recently-published book on "The Mechanical Triumphs of the Ancient Egyptians," that a huge solid stone statue is more imposing than anything built up in small pieces. What are the Goddess of Liberty (150ft. high) at the entrance to New York Harbour or the Sleeping Buddah of Bangkok (160ft. long), both hollow, in comparison to the granite statue of Rameses the Great! "They need care to prevent decay, and they will never remain of themselves an everlasting monument of the Godlike power of a king." But the problem is, How did the Egyptians erect such wonders? There have been a great number of theories expounded, but after all the old one of the inclined plane is the most probable and the most satisfactory.

There is no doubt (or there is ample reason to believe) that the Egyptians were acquainted with the principles of the lever, the wedge, the wheel and axle, and the screw. The weighing of the heart as described in the Book of the Dead (a work already ancient more than six thousand years ago) shows a lever with the fulcrum between the power and the weight, and the shadoof (for raising water) is another example that might be mentioned. Then the sagguieh, which no less an authority than Viollet-le-Duc says was common in Egypt in the first three dynasties, contains the principle of the capstan and the windlass. Most writers do not think the use of the pulley was then known, but Commander Barber maintains (by Queen Hatasoo's "Expedition to Punt") that it was.

As already stated, the inclined plane offers the most feasible solution of the problem under consideration. The Pyramids, it has now been conceded, were tombs, and nothing but tombs. When they were built labour and material were unlimited. The first stones were dragged from the quarry to the site and there laid. Then the incline was built of sun-dried bricks, and it increased in length as the structure grew higher and higher, until eventually it was miles long. The heaviest stone in the Pyramid of Cheops weighs sixty tons. Assuming it was placed on a kind of cradle, and grease employed to reduce friction, a force of twelve tons would then need to be applied in order to drag the block up the incline—that is, about 900 men. (M. Le Bas, who brought the Paris obelisk from Luxor in 1832, estimated then that one-fifth or one-sixth of the total weight of an object was ample for all grades up to 1ft. in 10.) It is a local tradition that an incline plane five miles long was employed in the building of the great Hindu temple in Tanjore, which conforms with the generally accepted theory respecting the Pyramids. As to the idea that the Egyptians possessed a number of wonderful inventions with which we are not now acquainted, this may or may not have been so; but there is no proof forthcoming that they did. The probability is that they executed their works with lever, wedge and other simple mechanical appliances, combined with an unlimited supply of material and a vast army of men. (It may be mentioned that Commander Barber's book is published by Messrs. Kegan Paul, Trench, Trübner & Co., of Paternoster House, Charing Cross Road, price 3s. 6d.).



A HALF-TIMBERED HOUSE.

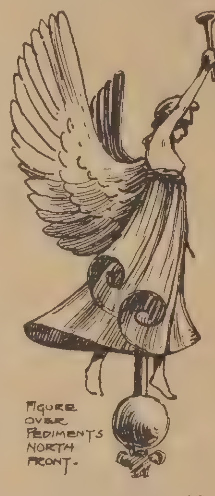
In Abeyance. IT is only natural that the zeal displayed in connection with the Queen Victoria Memorial should now have abated, leaving matters in abeyance for a while; but during this time the five selected architects are still busy with their designs, and it is probable we shall hear little further of these till they are exhibited at the end of June. Whether the committee will then put into practice the general demand for a public competition remains to be seen, but we are inclined to think they will not. We do not see how, having embarked upon their scheme, they could very well inform the chosen architects that they had changed their mind and would not therefore require their services.

With Special Sketches by J. Jeffrey Waddell.

THERE can be but one opinion about the International Exhibition now open at Glasgow; it is undoubtedly a great success, both as regards the buildings and the exhibits contained within them. Since Prince Albert planned the great gathering of the industries of all nations which marked the close of the first half of the nineteenth century, similar displays have been held in many countries. Some have been attended with success, others have been marred by failure; but the general effect of them all has been to promote friendly intercourse among the races. Scotland came late into the field, and the last quarter of the century had run many years of its course before anything of an international character was attempted. Although slow in beginning, however, the people showed that they knew how to succeed. In 1886 Edinburgh organised an exhibition memorable on account of its wealth of art treasures, and then two years later came the Glasgow display, the success of which is visible in the handsome building at Kelvingrove, which will, before many months are over, accommodate the celebrated collection of pictures belonging to the Corporation. Other exhibitions there have been, but those mentioned will be most widely remembered. The Exhibition of 1888 occupied the plain opposite the University, and the promoters of the present enterprise did not see that they could do better than use it again. More than two years have elapsed since the project of organising an International Exhibition in 1901 was decided upon, and during that interval the Executive Council worked most assiduously to perfect the details of the vast undertaking. The buildings, which extend over more than 100 acres, are divided into three great sections—the Industrial Hall, the Machinery Hall and the Art Galleries. With the exception of the Machinery Hall, together with the boiler and dynamo house, they are situated in Kelvingrove Park, and on the slopes of Gilmore Hill, the site of the Exhibition of 1888. The Machinery Hall is situated on Bunhouse Grounds (about six acres in extent) on the south side of Dumbarton Road, but connected with Kelvingrove Park by a wide bridge.

One great advantage possessed by the site is its hilly and diversified nature. Most exhibitions are all on the flat, but in Kelvingrove Park there is hardly any flat. It is in reality a ravine or glen, which must once have been wild and romantic, but is now subdued to the uses of an artificial pleasure ground and surrounded by houses or other buildings. The river Kelvin enters through a deep cleft, from which the hills rise abruptly on both sides, curves sharply round, and then winds away in the opposite direction. The banks of this winding stream are the park. The north bank, on the top of which the University stands, is steep and lofty all along; the south bank, high at first, slopes down and spreads out into more undulating ground. The main buildings occupy this undulating ground and extend along the whole length of it in a broken and irregular line, with separate pavilions and kiosks dotted here and there; but the Exhibition is not confined to the south bank, as one rather supposes at first sight. It extends also to the steep side opposite, below the University, and visitors should not miss this part. Here are a lighthouse, a large restaurant, and a whole street of important private stands high up the hill, and below them again, close to the river, a street of amusements.

The best point of view is the hill close to the lighthouse or the large restaurant near it. There you have the whole thing laid out before you from end to end, beginning with those fantastic Russian roofs and pinnacles on the extreme left and ending in the Machinery Hall on the extreme right with the great central hall in face, a cluster of towers and minarets, surmounted by gilded dome and soaring white-winged figure, which seems to be taking flight upwards into the sky, so lightly it touches the golden ball at its feet, so airily it is poised, gleaming white like a sea-bird in the sun.



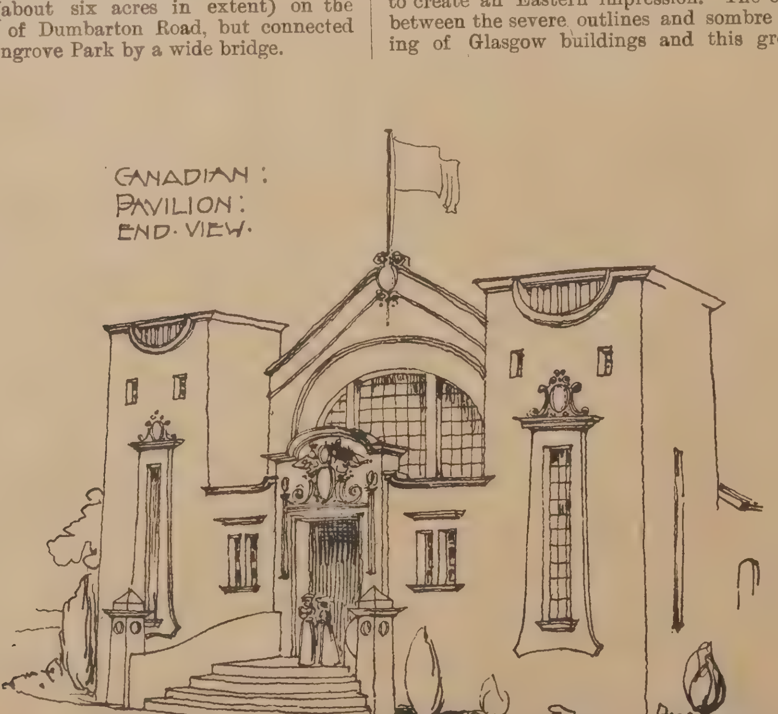
The prevailing colour is pure white, set off with harmonious reds, greens, gold and sky-blue. The prevailing form is Oriental, in suggestion rather than in strict design. The Moorish spirit of the Spanish style, which has been largely used, combines with Byzantine forms, minarets, cupolas, kiosks, bungalows and pagodas to create an Eastern impression. The contrast between the severe outlines and sombre colouring of Glasgow buildings and this group of bright, fanciful and bizarre erections suddenly reared in their midst is startling. It is a sudden transition from the most uncompromising prose of everyday existence to fancy, imagination and romance. And then you find, after all, that the romantic exterior is only a setting for all that is most strenuous and actual in the real world of to-day.

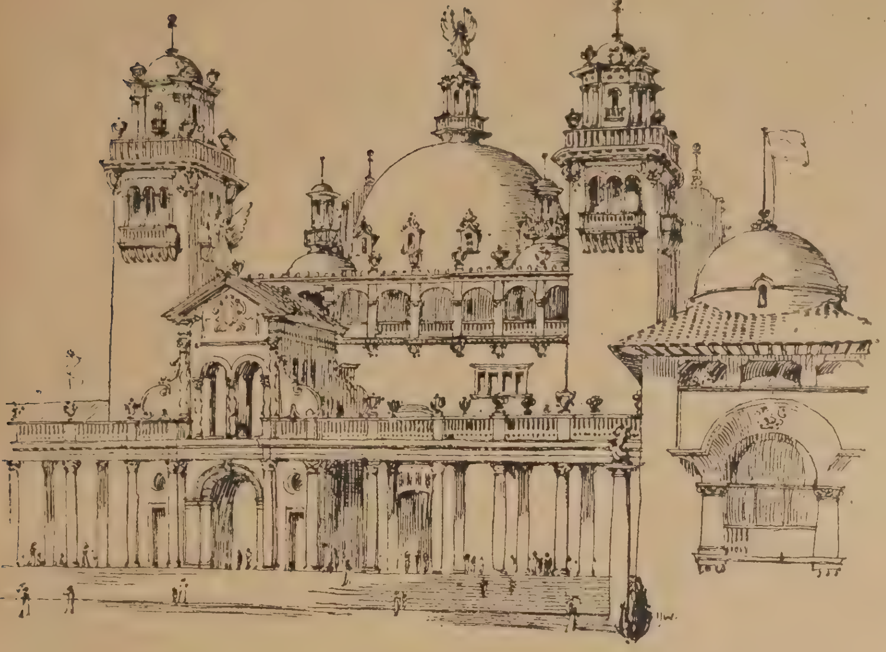
With regard to the disposition of the buildings, however, a Glasgow architect writes in the "Glasgow Herald" as follows: "In the all-important matter of plan, and in the first place, as regards the distribution of the various buildings throughout the grounds, it is regrettable that more attention has not been paid to the symmetrical arrangement of these on main axial lines. The irregular nature of the ground to be dealt with no doubt rendered this difficult of achievement, and the fact that the number and importance of the minor buildings were not anticipated when the scheme was first set afoot must also be taken into account. Still the fact remains that the general effect is rather that of a jumble, picturesque undoubtedly, but not comparable with the grandiose impression produced by long vistas of buildings, culminating in a central dome or other important feature, such as has characterised previous Exhibitions elsewhere, and not less notably Glasgow's rival across the Atlantic, the Pan-American Exhibition being held in Buffalo this summer."

The exterior of the Exhibition is designed after the style of an Eastern palace. It is in every way a bold design, and at the same time reveals qualities of restraint and judgment. Mr. James Miller, the architect (who was awarded the first premium of 200 guineas in open competition), has chosen as his style of a building a phase of Spanish Renaissance which flourished in the sixteenth century; but although the design is touched with Spanish characteristics, the general feeling is decidedly Eastern. There is great freedom of detail and exuberance of ornament, especially shields and vases, of which Mr. Miller always makes a feature: his balustrades also have always great originality and beauty of outline. In general character and picturesqueness the buildings harmonise well with the new Art Galleries. The style is most conspicuously developed in the Industrial Hall, which constitutes the main portion of the Exhibition.

The grand, or ceremonial, entrance is towards the Park, in the centre of the north facade, nearly opposite the bridge to the east of the Museum. Here the architect has displayed much originality. The front of the building is deeply recessed, so as to form a piazza about 200ft. long by 100ft. wide, behind a double range of classic columns 30ft. high, which, forming a screen nearly 200ft. long, continues the line of the north part of the buildings. Right round the whole building there runs an arcade of arched windows, the openings being divided by balustrades, which are supported in a very artistic manner on cherubs' heads moulded into the cornice beneath. These arches are flanked at the end of each bay with corner towers about 32ft. square, rising to a height of almost 60ft. The towers are surmounted with flattish domes—a feature of the period from which the style has been taken—terminating with flagstaffs carrying national flags. At the centre of the side wings there is an ornate hanging Spanish balcony, at the top of which is a figure emblematic of the Age of Electricity.

The approach to the grand entrance is made by a great flight of steps, rising from the main promenade in the Exhibition. This promenade extends from the Russian section, and has a continuous stretch on the east side past the Canadian section, along the front of the Industrial Hall and Art Galleries, terminating at the east of the Kelvin valley. Entrances of a less imposing character are provided in Sandyford Street and Gray Street. The central feature of the former entrance is entirely different from that in the main facade. It is flanked by two tall towers, and projecting towards the street there is a huge semi-dome bulging out into a verandah, thereby giving a variety of curve which harmonises well with the straighter lines of the towers and gables behind. The Gray Street front is flanked by two tall towers, about 120ft. high, with a great, deeply-recessed semicircular arch springing about 20ft.





VIEW OF DOME AND TOWERS FROM THE RIVER KELVIN.

off the ground, and nearly 50ft. in diameter. A verandah runs along the whole length of the towers. There is also an entrance to the Exhibition from Dumbarton Road, opposite the main entrance to the Art Galleries, leading into the main avenue.

The striking feature of the whole design, however, is the group of towers in the centre of the Industrial Hall. This occupies the centre of the grounds and faces the University The building is 700ft. long and 330ft. wide, and covers an area of more than 23,000 sq. ft. It consists of a great central dome, surrounded by four huge towers, rising to a height of about 160ft. From the apex of the dome, which is 135ft. from the ground level, there rises a beautifully-decorated fleche, 32ft. high. Resting on the fleche there is a large winged female figure of "Light" by Mr. Albert H. Hodge, of London. It is 12ft. high, the wings stretching 12ft. The right arm is extended upward, and in the hand she carries a torch electrically lighted, while in the left hand she bears a branch of palm. The lips are parted as if making proclamation. On the head is a helmet, while the robe from waist to ankle spreads out in ample folds. The main avenue of the Industrial Hall has a roof span of 103ft. designed on the "three-hinged arch" principle to counteract the expansion and contraction due due to changes in temperature.

The interior of the dome is decorated in colour and by groups of figures emblematic of Art, Science, Industry and Commerce. The spandrels are ornamented in a very effective way by colossal groups representing the Triumph of Navigation, and modelled by Mr. Albert H. Hodge. Immediately under the dome is a colossal figure of the King. The four towers which surround the dome at an effective distance form at their base the corners of an open arched balcony, to which visitors have access by means of two electric lifts in the south-east tower and by staircases built within the north-west tower. This balcony is 500ft. in circumference. Between the dome and the four main towers, and in line with the diagonals of the latter, have been erected four artistically-designed minarets. Apart from the elegance of the decoration, the whole group of minarets, towers and dome makes a unique spectacle, and gives a bold and striking character to this central part of the design. The cupolas of the four great towers, and also the cupolas of the minarets, are covered with gold; the main building is finished in pure white, while the roofs of the domes are painted pale green.

A fine contrast is made by the decorative treatment of the eight corner towers. These are covered with red Spanish tiles, the corrugated iron running along the roof between the towers being painted a bright orange tint, while the woodwork of the red-tiled wide-spreading eaves is treated in green.

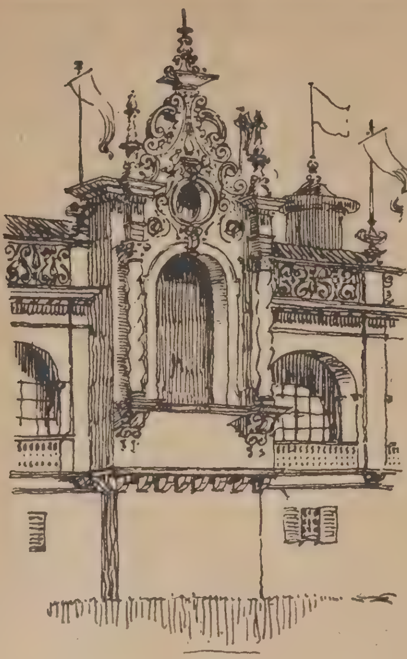
The whole of the external finishing of the buildings, including all the decorative work, is formed of fibrous plaster, composed of stucco, canvas and wood. This material is run into a mould and allowed to harden. The plain work is made in boards about 2ft. by 4ft. and $\frac{3}{4}$in. thick, nailed to a wooden framing, pointed, and then flushed up in stucco when in position. The ornamental work is cast into large moulds of the same material. Messrs. George Rome & Co. undertook the work. Quite half a million yards of cloth have been used, and the plastered work has cost altogether something like £25,000.

Far eclipsing any foreign exhibit in the grounds, the Russian section is deserving of special notice. It is the largest and most costly section ever staged by the Tsar's Government at any exhibition, and £30,000 was voted for its support last year. The space allocated to Russia covers 29,705 sq. ft. in the grounds and 11,131 sq. ft. in the Industrial Hall. The chief feature, or features rather, are the four buildings which have been erected at the north-east corner of the grounds. The buildings are almost entirely constructed of wood, and were built by Russian artisans sent over to this country about the New Year. There were 180 men employed, and as the work took fully four months an idea may be formed—even allowing that the visitors are slow tradesmen—of the nature of their handiwork. The kiosks were designed by a prominent Russian architect, M. Zelenko, of Moscow, and erected under his personal supervision.

The designs are intended to represent the old national architecture of North Russia. They are not copied from any existing buildings, but from old prints and drawings, various details being taken from different sources and put together. This explains the fantastic effect, as there is not only a mixture, but the decorations which may have been suitable enough on a small scale, in private houses for instance, are here magnified to colossal proportions. For the purpose of attracting attention nothing could be more effective. These huge and curiously-shaped structures, with their bright red and green roofs, draw the eye almost more than anything else in the Exhibition. The agricultural pavilion is being prepared inside for the reception of the Tsar, who will visit the Exhibition. The whole enterprise may be regarded as a deliberate step in that policy of commercial development of which the Siberian Railway and other large undertakings are recent signs.

The Canadian Pavilion is very effective. Messrs. Walker & Ramsay, of Glasgow, were the architects. The building measures 180ft. long by about 60ft. broad, and has 11,000 sq. ft. of space for exhibits. The Canadian Govern-

·THE· MAIN·ENTRANCE·
·SANDYFORD·STREET·



GABLE, SOUTH FRONT OF MAIN BUILDING.

ment have taken up the matter with great enthusiasm, and every State in the Dominion is represented.

The Grand Concert Hall, a circular building having a wide gallery and promenade supported on cantilevers, is connected by a covered way with the Industrial Hall. The structure is best described, in Mr. Miller's words, as a gigantic steel umbrella. The dome is coloured blue on the outside. With regard to the entrance front, however, one does not look for, or even desire, purity of style in such work; but angle pavilions of Venetian Gothic, a central doorway and balcony Italian in scheme (though certainly not in proportions), with connecting wings closely based in design on the loggia of a Spanish "patio," if the combination is to be successful, require more care and skill in the blending than have been bestowed in the present instance. The hall itself is admirably arranged, though it has not been improved by the colour decoration, particularly in the interminable repetition of shields with the same armorial bearings "picked out" in gold and colours on the balcony front. On the whole, this portion of the Exhibition is the least satisfactory, and one is as sorry that it is to be permanent as that the centre group of dome and towers on the main building must be temporary. The hall, moreover, is not a success acoustically.

The internal colour decoration throughout the various buildings, and more especially the lack of it, forms indeed one of the least satisfactory features of the scheme. The decoration of the main dome, designed and carried out by Messrs. Dall & Neave, is not altogether successful. The individual figures are good, some of them particularly so, but the scheme is not sufficiently large or dignified for such a situation and the vast scale; and the colour is thin and not particularly harmonious.

By contrast, the sculpture work throughout the Exhibition is worthy of the highest praise. In this Mr. Albert Hodge, with his assistant modellers, Messrs. Holmes & Jackson, has rendered the architect yeoman service.

(*To be concluded.*)

A New Church at Telford Park is being erected, and is to be dedicated to St. Thomas. The plan of the church is cruciform, and the style Transitional. At present only the nave is being built; the additions of chancel and transepts are to be added as funds come in.

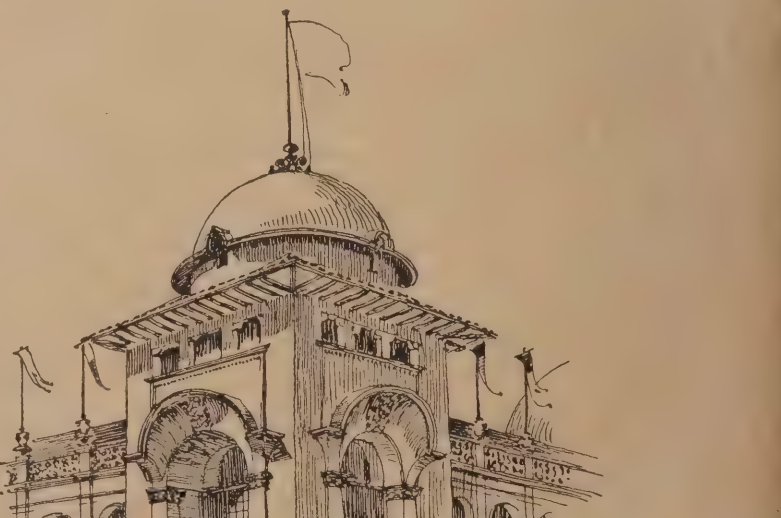
A Town Hall for Cheltenham recently formed the subject of a Local Government Board enquiry into an application by the Town Council for sanction to a loan of £35,000. It is proposed to be erected upon the northern portion of the lawn surrounding the winter garden structure in Imperial Square.

PLYMOUTH CITADEL.

PLYMOUTH CITADEL, which figures prominently amongst the few remaining ancient institutions in the borough, is undergoing extension, and the increased accommodation will entail an expenditure of something like £40,000. The fortress is being transformed into an artillery depot. Entering the Citadel by way of the famous gate which overlooks the town—the bold and spirited carvings on which are supposed to have been the work of Sir Christopher Wren—one is faced by a tall block of buildings, for the officers' quarters and mess, forming a striking contrast to the erections close by. The buildings are of local limestone, with Portland stone dressings.

On the east curtain wall of what a few years ago formed the inner ramparts of the old historic fortress an effort is being made to engraft in the new building some of the spirit of historical antiquity with which it is surrounded. Access is only obtainable on one side. The demolition entailed for the erection of the new recreation and soldiers' block affects the least interesting portion of the fortress, and the elevation has been so designed to disturb as little as possible the repose of the old ramparts. The old massive granite plinth and string course are rebuilt in the new work at their original level, thus preserving that continuity of long low lines with which the eyes have become familiar, and which is characteristic of the Citadel. The walls are built of local limestone with Portland stone dressings, a 3in. cavity and a lining of 9in. brickwork. In the centre of the quadrangle has been placed the fine old statue of George II., which has been removed from the site of the new officers' mess. The statue was erected in 1728, at the expense of Captain Louis Dufour, and is the work of an artist named Robert Pitt The centre portion of the eastern elevation bears a carving of the royal arms in the pediment. The work is done in Portland stone, and immediately below are the words: "Built on the old ramparts in the 60th year of Her Majesty's reign." The wings of the block, which form the quadrangle, each contain accommodation for thirty men, offices and bath and cook-houses. The tail ends of both wings are only about half the elevation of the main buildings, and have granite porticos. The general arrangment and treatment of the interior is simple. The recreation block, with its reading and recreation-rooms, coffee-room and bar, grocery shop and manager's quarters, is placed in the centre, with the long soldiers' barrack wings flanking it on either side, and, at a point dictated by the conditions of the site, returns to form three sides of a quadrangle. The cook-houses and baths terminate the wings, and are, therefore, conveniently situated for all the barrack-rooms. In close proximity to the northern wings of the soldiers block a large building—a canteen and recreation-room—is nearing completion. Like the large block of buildings to be erected for married men's quarters outside the east curtain wall, adjacent with the roadway, it consists of local granite, with Portland stone facings. The architect who has suggested and designed all the Citadel additions and improvements is Mr. T. Rogers Kitsell, F.R.I.B.A. The foundation of the Citadel is said to have been laid on June 12th, 1671; but six years before that date the great fort on the Hoe is recorded to have been commenced, taking the place of a small fortress built with money raised by means of a tax laid upon pilchards brought into the port. The Citadel was designed by Sir Bernard de Gorme, and whilst it was in progress the works were inspected by Charles II. and his brother James. It consisted of five bastions, with intermediate works, and was originally mounted with 165 guns. Immediately outside the northern rampart of the Citadel, on ground granted by the Corporation, it is proposed to erect headquarters for the 2nd Devonshire Volunteer Artillery, W.D.G.A. The work of designing plans is now in hand. The covered drill-shed will be about 120ft. by 60ft., and the armoury 30ft. by 20ft. There will be spacious rooms for all ranks, coffee bar for the gunners and junior non-commissioned officers, an orderly room, adjutant's office, lobby, store and caretaker's premises. The frontage, which will probably be of local limestone with Portland stone dressings, will have a northern aspect.

Twenty New Almshouses at Wakefield are being erected in Denby Dale Road, ten for men and ten for women, with a nurses' home in the centre, for the Governors of Wakefield Charities.



ANGLE PAVILION, GLASGOW EXHIBITION.

HITCHIN NEW TOWN HALL.

THE new Town Hall at Hitchin was opened recently, after having been in course of erection for eighteen months, on the site at the top of Brand Street, with a frontage of 78ft. The accommodation provided in the building is as follows: The entrance vestibule, which is 18ft. 6in. by 17ft., is entered from Brand Street, under a deeply recessed arch. The vestibule contains a ticket office, a fireplace, two doors into the hall, and opens by arches on the left to the principal staircase, and on the right to the communication corridor. This corridor, which is 6ft. wide, and with the staircase at the far end, runs the whole length of the hall, is lighted by glass domes in the ceiling, and has entrances into the hall and an emergency exit door into the joint right of way between the Town Hall and Blue Cross buildings. This corridor is a special feature of the building. As well as the above, in the front or public office block, are contained, on the ground floor the town surveyor's office 14ft. 6in. by 14ft. 6in., with ample cupboard room; the gallery entrance into Grammar School Walk and gallery stairs; the principal staircase, and ladies and gentlemen's cloak-rooms with lavatories to each, the gentlemen's being entered from a door off the corridor. In the basement is a heating chamber. On the first floor are the landing of the gallery staircase with a small ticket office and a pass door into the principal staircase landing. The gallery entrance and the stairs, which are constructed of teak 2in. thick, is so arranged that it can be used as the ordinary office entrance, but during entertainments the pass door at the top is intended to be locked. On the first floor are also the town clerk's office, 19ft. 3in. by 14ft. 6in., a waiting lobby to the Council Chamber, 9ft. by 7ft. 6in., with a secondary entrance to the gallery; a committee room, 11ft. by 10ft., and the Council Chamber—a large room 30ft. long by 19ft. 3in. wide, and 16ft. to the highest part of the ceiling. The hall is in length 76ft. 6in., and the breadth is 40ft.; the height to crown of ceiling is 26ft. and to the spring of the arches (that is to the top of cornice below the windows) 11ft. 6in. It is lighted by ten large semicircular windows, and four dormer windows, all of which have swing casements, and has a gallery across one end. The entrances are as follows: Two from the vestibule, an emergency exit to the Grammar School Walk, and two exits into corridor. There is a communication door from the hall to the stairs to the stage, &c. The stage floor is 3ft. 6in. above the hall floor, and is laid to a slope upwards from front to back of 6in., and there are steps at each side on to the hall floor. The width of stage is 26ft.; the depth, from face of pilasters to the back wall is 18ft. 6in., and the stage projects into the hall 2ft. 6in., making a total depth of 21ft. There are doors communicating with a retiring room on the Blue Cross New Building side and with the stage exit and retiring rooms on the Grammar School Walk side. The retiring rooms from the stage are 11ft. by 10ft. on the Grammar School Walk side, and on the Blue Cross Brigade building side 17ft. by 7ft. 6in. The latter room has a fireplace, and each has lavatory accommodation attached. There is a third retiring room 14ft. 6in. by 13ft. 8in. on the first floor on the Grammar School Walk side, approached by stairs 3ft. wide from the stage entrance. On one side of the stage is arranged a storage for stage properties, divided from it by movable shutters and a hinged door, and at the back of the building is a large yard, a portion of which is covered by a glass roof forming a shelter for storage purposes. The whole space under the stage block is used as a chair storage, and there is also kitchen accommodation.

The architectural style of the building may be described as a simple treatment of the late English Renaissance. The main object in view in the structure was to bring the building into line with such fine houses as the old Brewery House in Sun Street, or the smaller houses of like character in Bridge Street, as well as others about the town. The circular form of ceiling to the hall was adopted for various reasons, the principle being that it was good for sound, and was economical in construction. The roof is carried by steel trusses which do away with all thrust, and reduce the load to a dead weight. The main front is towards Brand Street, and consists of a central portion containing the principal entrance in a deeply recessed arch, and flanked by Ancaster stone pilasters which run right up to the cornice; the space above the arch and between these pilasters is filled with rough-cast. It is crowned by a pediment containing a device executed by a modeller from Mr. Gilbert Seale's studio in London, who executed all the ornamental plasterwork. It is in Portland cement, and is built up on the face of the brickwork in some places to a depth of 8in. Flanking this central portion are six windows on each side, the larger ones being on the first floor, set in red brickwork, which is the general wall facing, and at the angles are Ancaster stone quoins; the set-off of the plinth is also of Ancaster stone. The window-frames and cornice are of wood, and the windows filled with lead glazing in small squares; the roof is of Sandy tiles. There are chimney stacks at either end, and the whole is crowned by a turret covered with copper. It was found necessary to reface the end of the adjoining building, and in doing this the opportunity was taken of throwing an arch across between the two, over the gate to the joint right of way. The sign of the hall to Grammar School Walk shows five semicircular windows high up from the ground, framed in rough-cast up to the buttresses and the eaves of the hall roof. In this latter are two of the dormers referred to before, and in the centre of the building is the emergency exit porch. The length of the hall is flanked at one end by the projection of the office block, and at the other by that of the stage portion. The brackets of fibrous plaster over the window-heads in the hall have a modelled ornament of roses and lavender, a compliment to Hitchin products. The same device of roses and lavender is carried round the stage arch, but in the cornice above the more usual architectural decoration is employed. In the council chamber over the fireplace is a piece of plasterwork, executed by Mr. J. Pepper, and the lettering is based on some old tablets in the town. The iron fireplaces are from the excellent stock of Messrs. T. Elsley, Ltd., who are also the executants of the gas pendants, which were specially designed by Mr. Geoffry Lucas. The tiles to the fireplaces are of Dutch manufacture. The door fittings are in bronze metal. The building throughout is fitted with curtain blinds by Mr. W. Phillips, Hitchin, those in the front being of taffeta, and adding to the appearance of the windows. In the hall they are of green cotton rep, answering the purpose of excluding the light during any afternoon performances. The stage curtain and frontispiece is of red cotton plush. It is managed from one side of the stage. All the curtains are on brass rods.

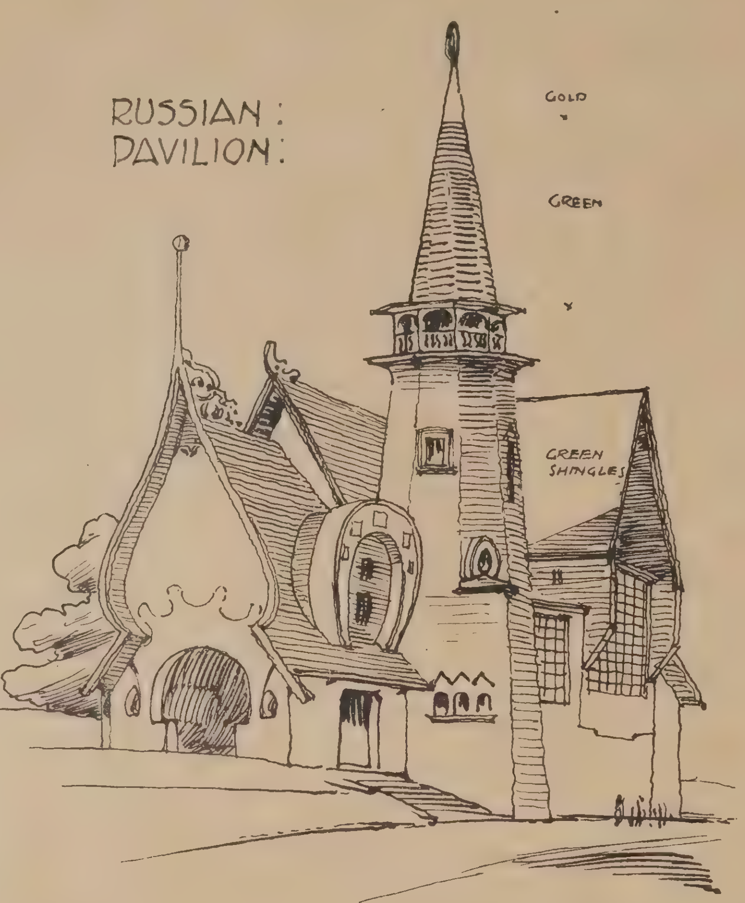
AND PROSPERITY · WITHIN · THY · PALACES : THE · EARTH IS THE
JJW.

As to the seating, accommodation is provided as follows: The body of the hall provides for fifteen rows of twenty chairs each, and fifteen rows of benches, each with twenty-two seats. The gallery has six rows of benches, each providing twenty-four seats, and two smaller ones, giving a total capacity of 780 seats, exclusive of stage and standing room. The gangway across the hall in front of the stage is about 4ft. wide, and that at the back of the hall 4ft. 6in. There are alsoe gang two sidways 3ft. 6in. wide, and a narrow one down the centre. As ample room had been allowed in the above calculations it is quite possible that when necessary the building will easily accommodate 1,000 persons.



For the new building Mr. E. C. Pinks, of Messrs. Pinks & Watson, Westminster, was the quantity surveyor; and the joint architects were Mr. E. W. Mountford, F.R.I.B.A., London, and Mr. Geoffry Lucas, A.R.I.B.A., Hitchin. The cost of the building has been £5,800.

The following is a list of the various firms engaged in the building or from whom articles were obtained: General contractor, Mr. S. Redhouse, senior, Stotfold, Baldock Stone, The Lindley Quarries, Ancaster. Mason's work, Mr. James Pepper, Hitchin and Shefford. Bricks, Messrs. Plowman, Henlow. Steel roof trusses, Messrs. Drew, Bear, Perks & Co., London. Roof tiles, Mr. A. F. Love, Sandy, Beds. Plasterer, Mr. Thomas Walker, Arlesey. Gas-fittings and general ironmongery, Mr. George Redhouse, Baldock. Heating apparatus, Messrs. C. Kite & Co., London. Fire hydrants, Messrs. Merryweather, London. Stoves, rain-water heads, gas-pendants and brackets, Messrs. T. Elsey, Ltd., London. Ornamental plaster-work, Mr. Gilbert Seale, London. Iron casements, Messrs. Crittal & Co., Braintree. Plumbing, lead-glazing and glass domes, Messrs. Jenkins, London. Lavatory fittings, Messrs. J. Tylor & Sons, Ltd., London. Iron railings and chains for hall, Messrs. Gatward & Sons, Ltd., Hitchin. Tiles for fireplaces, Messrs. M. Van Straaten & Co., London. Speaking tubes, Messrs. Sheath Bros., London. Door furniture and panic bolts, Messrs. Charles Smith & Sons, Ltd., London and Birmingham. Glazing in yard, Messrs. Rendle & Co., Ltd., London. Asphalt for flats, Val de Travers Co., London. Gallery seats and fittings in cloak room, Mr. Joyner, Hitchin. Benches for hall, Mr. Taylor, Luton. Curtains throughout, Mr. F. W. Phillips, Hitchin. Incandescent gas by-pass supply, Mr. W. R. Phillips, Luton. Matting for hall and doormats, Mr. C. R. Burrows, Hitchin. Ditto for council chamber and dressing-room furniture, Messrs. W. Upchurch & Son, Hitchin. Council chamber tables, Messrs. P. H. Barker & Son, Hitchin.

Workmen's Dwellings for Hornsey.—The Hornsey District Council has purchased a further six acres of land adjoining their workmen's dwellings at a low rate, and this is to be utilised for the erection of more dwellings for the working classes.

EASTBOURNE PIER.

A NEW PAVILION is being erected on the pier at Eastbourne. From the summit of its central dome a view can be obtained of the majestic Downs to the westward. The dome is divided into two storeys, the upper one being intended for a camera obscura. The lower floor will be let as an observatory, museum (in miniature) or mutoscope exhibition. The dome is to be brilliantly illuminated at night by incandescent electric lights. The exterior of the dome and the other roofing is covered by zinc tiles. The contractor is Mr. Grace. The floor (about 10ft. wide) of the balcony running round the building at a height of several feet above the deck is of asphalt. The installation of the electric light is costing £1,000; and in addition there are a number of gas lamps on the balcony and elsewhere. These will be available in the event of any breakdown of the electric light supply. Ample provision has been made in respect of emergency exits, by which when thrown open the audience will be able to make their way out in a few minutes. There is to be accommodation for some thirteen hundred people. In the auditorium (on the ground floor) there will be seven rows of stalls and eleven rows of chairs. These will be tip-up theatre seats, and they will be upholstered in red plush. Upstairs the wide balconies will have four rows of seats, and there will be ample space at the back for a promenade or smoking lounge. The proscenium has been constructed of a composition into which plaster-of-Paris enters largely, and the prevailing colours are white and gold. The front of the balconies will be ornamented with designs illustrative of music and the drama. Outside the inner balcony, directly facing the stage, there will be a bar, with two tea-rooms adjoining it; and the principal bar downstairs will have walnut fittings, and will be on the western side of the building. Lavatory accommodation for ladies and gentlemen has been provided, Jennings' latest sanitary fittings having been used. The dressing boxes for bathers will accommodate a number of swimmers. Some rooms to let as shops form part of the pavilion. There is also a room for the directors.

AN INCIDENT OF THE PARIS EXHIBITION.

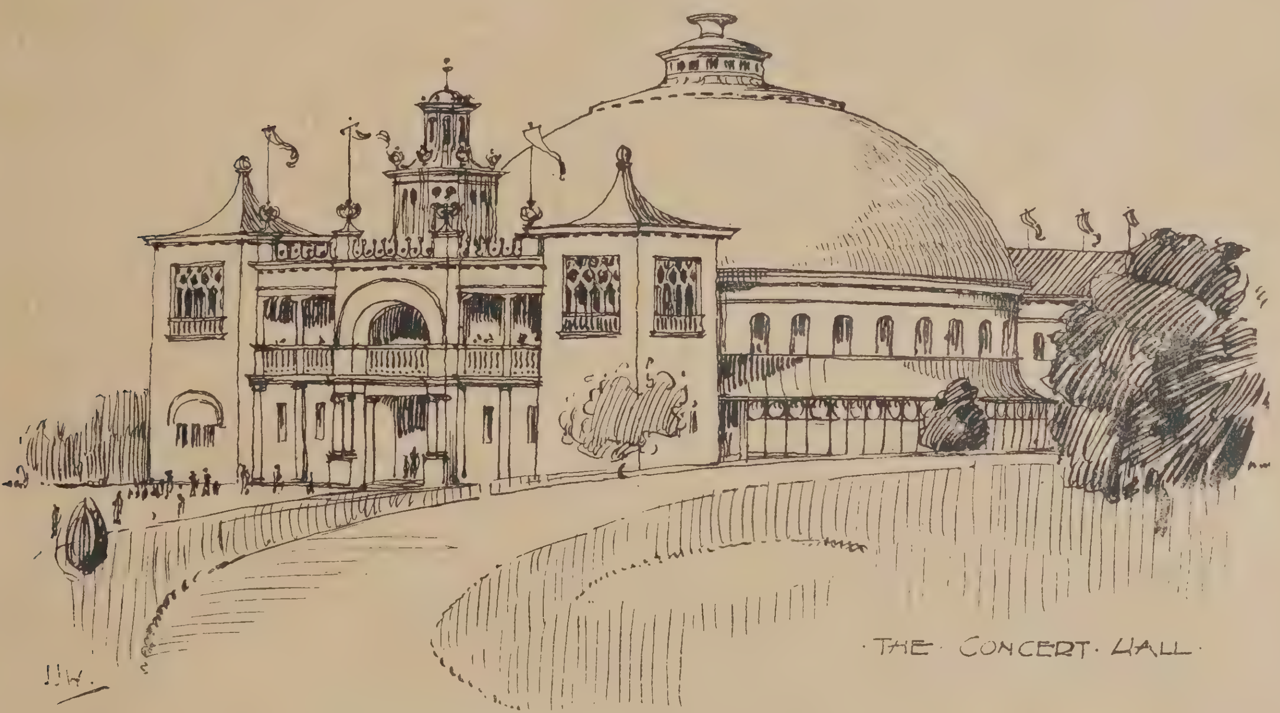
IN their report respecting the exhibit of Great Britain at the Paris Exhibition of 1900, presented to the King, the Commissioners state that one of their greatest difficulties—one, indeed, which threatened to become acute—arose in connection with the representation of the Colonies and India. It was part of the French scheme that colonies and dependencies should not show in the main buildings, but should erect pavilions at their own expense in the Trocadéro Garden. More than half the space was reserved for the French dependencies, and there were so many foreign claimants for the remainder that the Commissioners were only able to obtain an area of 58,884 sq. ft., which, according to the plans, yielded 36,000 sq. ft. of exhibiting space. This was so inadequate that many of the Colonies declined to exhibit, and the colonial representation was confined to Canada, Ceylon, Western Australia and Mauritius, which shared the space with India. No conditions had been attached to the allotment in the Trocadéro Garden, except that the larger trees should not be disturbed, and the Commissioners assumed that they were at liberty to use it to the best advantage. Designs for buildings were accordingly prepared by the Indian and Colonial Committees, and were submitted to the administration for their approval; but, to the Commissioners' surprise, these designs, the fruit of much time and labour, were rejected on the plea that they were out of harmony with the ideas of the administration, since the buildings were pronounced to be too high and to occupy too much of the ground. The Commissioners found themselves confronted on the one hand with the refusal of the French authorities to authorise the execution of the plans, and, on the other, with the refusal of the Colonies to submit to any reduction in their space. It was, in fact, an *impasse* from which there was no apparent escape, and there was reason to fear that the Colonies would withdraw altogether from participation in the Exhibition. Such a lamentable result was, however, averted, and by the joint efforts of Sir Edmund Monson, Her Majesty's Ambassador, and others, a compromise was arrived at by which the French authorities agreed to increase the space, in consideration of the designs being altered to meet their views. Fresh plans, which were accordingly prepared, were accepted, and a very troublesome incident closed with nothing worse than the loss of seven and a half months of valuable time.

LEICESTER AND LEICESTERSHIRE SOCIETY OF ARCHITECTS.

THE twenty-eighth annual report, of which we have received a copy, states that the membership now numbers 100, being an increase of fourteen since the last report was issued, while the statement of accounts shows a balance carried forward of £148 1s. 1d. The late Bishop of London (Dr. Creighton) and the late Mr. Joseph Goddard, F.R.I.B.A., were members of the society. In December last a communication was received from the Leicester Master Builders' Association asking the Council to receive a deputation to discuss certain matters affecting contracts and quantities. This was agreed to, with the result that the Council now make the following recommendations: (1) That where contractors are invited to tender, the lowest tender should be accepted. (2) That a clause be included in the quantities to provide for insuring workmen against accidents in a similar way that insurance against damage by fire is included. (3) That payments be made in the following manner: 80 per cent. of work executed during course of erection, 10 per cent. of the remaining 20 per cent. on completion of the work, 5 per cent. of the remaining 10 per cent. at the expiration of half the period of maintenance, and the remaining 5 per cent. final payment. That the accounts be settled within a reasonable period after the final accounts have been deposited with the architect by the contractor. (4) That on all large contracts an item be included in the quantities for damage that may be caused by excessive carting to the highways outside the Leicester borough boundaries. (5) That it is but fair to contractors the schedule of prices should be held by architects as a private and confidential document, and due care be taken that the contents are kept secret for all time. (6) That with regard to prime costs the Council cannot advise the inclusion of a specified profit, but suggest that the words "and builder's profit" follow as a separate item after every prime cost sum.

It has been decided to offer the sum of five guineas for the encouragement of the study of architecture at the Leicester School of Art, the prize to be awarded to the student who does the most meritorious work at the school during the winter session 1901–1902. The prize is to be spent in an architectural sketching tour of not less than ten days' duration. The Committee retain the power to withhold the £5 5s. in case the sketches are not considered satisfactory.

The report is illustrated by three drawings of old buildings in Leicester by Mr. John Fulleylove, R.I., honorary member of the society, and by a drawing of the south aisle of Gaddesby Church from the pen of Mr. A. H. Hind, a good specimen of fourteenth-century work.



·THE· CONCERT· HALL·

HULL'S NEW COMMERCIAL EXCHANGE.

THE new Pacific Commercial Exchange, Ltd., in High Street, has been built to the architectural design of Mr. B. S. Jacobs, of Hull, on the lines of the Great Baltic Exchange in London. The entrance to the new 'change faces Bishop Lane and is vis-a-vis to the entrance of the Hull Exchange. To the right, on entering, is found a spacious waiting hall and staircase, the former having an oak floor and high oak panels around the walls. The staircase, which is covered with thick Anglo-Turkish carpet, is also constructed of oak, with mahogany handrail and newels. Passing through the swing doors on the ground floor the main hall is entered. This is a lofty room 64ft. long and 41ft. wide, with aisles on either side, in which are tables of mahogany with beaten copper tops and chairs. The walls are in light terra-cotta and white, and the columns, which have white panelled outer covers, stand on hard brick pillars driven 28ft. in the ground. The room is lighted by a powerful installation of electric light, fixed on electroliers of beaten copper and wrought-iron. The hall is aired by a couple of electric fans, and heated by low-pressure steam-radiators. Above the entrance doors is a balcony. At each end of the hall are deeply-recessed chimneypieces and fireplaces. On the left of the entrance is the hall porter's lobby, and on the right the members' writing-room, furnished on an elaborate scale, with bookcase, writing desks, &c. At the far end are the lavatories, serving-room and telephone-room, the latter containing six telephone boxes—two trunk wires and four locals. Above these is a mezzanine floor comprising larders, store-room and serving-room, beer and wine cellar and cigar-room. Up the staircase is the lounge—an elongated room 32ft. by 17ft., furnished and carpeted luxuriously at considerable cost. This has communication direct with the restaurant, 42ft. by 27ft., which is entered by Classic swing doors, with bevelled plate-glass panels. The ceiling of the restaurant is carved and deeply panelled and enriched. At the far end of the board-room are two cross ventilated serving corridors leading to the kitchens and serving-rooms. The kitchens are fitted with a special Eagle range, gas grilles and cookers and hot water, hot plates, &c. Above the kitchens are the caretaker's rooms, and above the lounge is the board-room and lavatories. Beyond the kitchens and at the same level is a servants' hall, steward's office and knife-room, &c. The new exchange has been erected by Mr. Walker Sanderson, contractor, Hull. The sub-contractors were Messrs. M. J. Peers (mason), R. H. Kenningham (plumber), Messrs. Dawber, Townsley & Co. (slaters) and Messrs. Dreyer & Co. (painters and decorators). Messrs. King & Co. were responsible for the electric lighting installation, electro wares, electric bells, grates and the cooking arrangements. The special hammered iron and copper electric-light fixings and wrought-iron palisading were supplied by Messrs. Norman & Ernest Spittle, of Birmingham, and the low-pressure steam heating radiators and electric ventilating fans by Messrs. Ashwell and Nesbit, London; the mahogany and other chimneypieces by Messrs. Lackenby, and the glass and china services by Mr. J. J. Bernard. The whole of the furnishing was done by Messrs. Bladon & Co., of the Bon Marche, Prospect Street, Hull.

A New Home of Rest, at Rostrevor, has been erected in connection with the work of the Girls' Friendly Society in Ireland. The site is in one of the best positions on Carlingford Bay. Mr. W. J. Watson, F.R.I.A., was the architect.

A NEW INSTITUTE IN WALWORTH.

THE new buildings in Larcom Street, Walworth, for St. John's Institute, erected through the munificence of Mr. Arthur Lloyd, of the "Daily Chronicle," have just been completed. There are four floors and a basement in the building, every foot of space being utilised. In the basement is the store for furniture required for concerts or lectures, as well as the heating chamber and apparatus. On the ground floor there are the men's gymnasium, the boys' gymnasium, and boys' reading-room, with a spacious entrance hall and fireplace. On the mezzanine floor is the gallery to the large gymnasium, to be used as a dressing-room, with shower-bath, lavatories and secretary's gallery attached. The first floor contains a meeting-room for allied clubs, a reading and writing room, and a large billiard-room fitted with two full-size tables. On the second floor are twelve cubicles 10ft. long by 5ft. wide for resident members, each being lighted by a separate window, a bathroom, and separate shower bath, with a range of lavatories, store-room, box-room, &c., and a dining-room. The kitchen and caretaker's rooms are placed in the attics. There is a lift serving all the floors, and hot and cold water is laid on to the sinks and lavatories on each floor. The furniture, which has also been given by Mr. Lloyd, is made in oak from designs prepared by the architects, Messrs. Dunn & Watson, of 35, Lincoln's Inn Fields, W.C. All the rooms and passages are lighted by electric light. The building has a frontage to Larcom Street of about 66ft., and the front wall is faced with salt-glazed bricks of a warm colour up to the gymnasium windows, over which there are fine balconies projecting from the billiard-room floor, shaped and moulded and enclosed with wrought-iron railings. Above this the walls are faced with yellow stocks with stone dressings. The entrance doorway has been treated so as to include the mezzanine and first-floor windows immediately above it, having pillars with carved corbels and carved cornice, finished at the top with a shaped and moulded head enclosing the arms of the Institute. The contractor was Mr. John Marsland, York Street, Walworth.

M. Felix Charpentier, the famous sculptor, was awarded a *grand prix* for his work at the Paris International Exhibition, and has recently been promoted to the rank of officer of the Legion of Honour.

A NEW BOARD SCHOOL FOR ST. ALBANS.

THE St. Albans School Board have just provided another school for boys on a site in the south-eastern portion of the city, comprising 1,860 sq. yds., or a little over one-third of an acre, in the Old London Road, near the new and growing neighbourhood of Priory Park, which has given its name to the schools. The site is at the end of the road nearest the town, and is situated about 275ft. above the sea-level, so that it is well away from the river. It has a frontage to the Old London Road of 105ft. and an average depth of 160ft. The school can accommodate 200 boys, and is so planned as to be capable of expansion so as to accommodate 300 without substantial alteration. The lighting in each case is from the left side. With a view to maintaining accurate levels, the school building has its length from north to south, thus presenting a short side only to the road, avoiding the inconvenience which would have been caused by reason of the decided decline of the ground from west to east. The building therefore stands along the top of the slope of the site, and additional advantages are thereby secured. The windows cannot be injured by buildings on adjoining sites, and they are so placed that every room gets the sun.

According to the good rule now sanctioned by the Education Department, the glass of the main windows is brought fairly near to the floor. The size of the windows has been determined by calculation so as to bear a fixed liberal relation to the floor area. A space is left on the west of the building for drainage, command of the roofs, &c. The size of the site will allow a little more than the minimum of space permitted by the Department when 300 boys are provided for. In the school, as now built, there is a schoolroom for 100, hereafter to be divided by a sliding partition, into two classrooms, each for fifty, and two classrooms for infants. The precaution has been taken to build the lobbies, cloak-rooms, &c., of the size that will be required for 300 scholars, so that enlargement in this portion of the buildings will be unnecessary to complete the school. The storeroom of the larger school is to be used as a masters' room for a time before the permanent masters' room is built.

The walls of the buildings are carried out in local red bricks. and the roofs are covered with Woburn red plain tiles. In the oak bell-turret is hung the bell from the house at Colney Park, which was sold when the old mansion was pulled down, and was acquired for this school. The floors in the passages are of Stuart's granolithic, and the rest of the floors are of pitch-pine blocks, of Duffy's Acme, D quality, laid herring-bone fashion in composition on a concrete bed. The heating is by Shorland's stoves. Fresh cold air is admitted by numerous Tobin tubes, some of large size, and the used air finds its way into the roof space and goes out at the gables, and by special ventilation flues arranged in the chimney-stacks.

The floors of the classrooms are in steps, so as to give the teacher a command of the boys, and also to enable the boys to see the blackboards and their teachers without effort. Where dual desks are used there are two on the floor of the classroom and three on the raised steps—five rows in all—the rooms being 22ft. wide where narrowest. Twenty inches of space is arranged for each desk, and passages 16in. wide are left between them. The desks used throughout the school were made by the Educational Supply Association.

The plans for these schools have been prepared by Messrs. Clarkson, architects, of Bricket Road, St. Albans, who have now completed four school buildings for the Board, or five if the Alma Road Infants' and Girls' Schools are counted as two. Messrs. Whibley & Jervis, of Alma Road, St. Albans, were the builders. Their contract was for £2,700. Mr. H. Tanner, of Sandridge Road, was clerk of the works. The lavatories and other sanitary appliances are from Messrs. Adams, of Leeds. The whole of the building is lighted by gas, the fittings having been supplied by the firm of Messrs. Strode & Co., while the blinds have been fitted by Messrs. W. Page & Son, of St. Peter's Street, St. Albans.

OBITUARY.

THE LATE MR. ARTHUR CATES.

THE death took place, at his residence, 12, York Terrace, Regent's Park, on Wednesday last, of Mr. Arthur Cates, the well-known architect, formerly of 7, Whitehall Yard. After leaving King's College School, Mr. Cates became a pupil of Mr. Sydney Smirke, R.A., and afterwards confidential assistant to Sir James Pennethorne. In 1859 he entered upon general practice as an architect, and continued in the active pursuit of his profession until 1898, when he retired. As an architect he acted for the Inner Temple and other public bodies and estates, and from 1870 till his retirement he was architectural adviser to the Commissioners of Woods and Forests for the Crown estates in London. From an early period of his career he was largely engaged as a referee and arbitrator in cases arising out of building and property disputes; and in later years his experience and authority in this branch of professional work were recognised by his appointment as chairman of the Tribunal of Appeal under the Acts of 1890 and 1893 and the London Building Act of 1894. Mr. Cates gave a large amount of time and attention to the affairs of the societies connected with his profession. He was for many years a member of council, and for four years vice-president, of the Royal Institute of British Architects, secretary to the Society of British Archæology, a vice-president in 1891 of the Biblical Archæological Association, chairman of the board of examiners in architecture from 1880 to 1896, and hon. secretary to the Architectural Publication Society. While holding the last-mentioned office Mr. Cates completed the production of the Dictionary of Architecture, at a cost of over £10,000. Besides his contributions to the work named and to the Dictionary of National Biography, Mr. Cates was the author of numerous communications to professional journals in support of his efforts to improve architectural education and to promote the establishment of professional examinations, in which he was ultimately successful. He was seventy-two years of age, and was buried on Saturday last.

THE LATE MR. ARTHUR CATES.

At Melksham Parish Church, in connection with the restoration, a figure of St. Michael has been erected in the niche over the north door. The figure is of Painswick stone, and was carved and fixed by Messrs. Harry Hems & Sons, the well-known sculptors of Exeter.

Coley Church, one of the oldest edifices in the parish of Halifax, is undergoing restoration. The alterations in progress include an enlargement of the chancel by the absorption of the old vestries, the provision of new vestries and the re-pewing of the church. The improvements are estimated to cost £2,000.

New Patents.

These patents are open to opposition until June 24th.

1900.—White Lead.—8,820. E. R. Blundstone, 14, Great Smith Street, Westminster, S.W. The process consists in making an alkaline solution of litharge in lactic acid or lead lactate and precipitating white lead from the solution by means of carbonic acid. One advantage is that the process can be carried out in the cold.

Urinals.—11,084. T. W. Twyford, Cliffe Vale Pottery, Hanley, Staffs. The body of the urinal is constructed in the ordinary manner, but the curved back is provided at the top with a continuous channel, covered by the eave depending from the coping. This channel is fed by a service pipe, and when full the water overflows down the back of the urinal in a thin unbroken stream. The use of sparge pipes is thus avoided. A second part of the invention, however, relates to the connection between a sparge pipe and the water-supply by a two-part fitting which allows the sparge pipe to be detached without disturbing any other part of the urinal.

Water Fittings.—11,087. T. W. Twyford, as above. This invention relates to a water-shunt valve for controlling the flow from a single source of supply to two different parts. The body is quadrant-shaped, and contains a wedge-like valve operated by an outside lever.

Brackets for Cisterns, Basins, &c.—11,146. T. W. Twyford, as above. The bracket is made of fireclay, but encloses an iron arm or rod which is built into the wall.

Lifting Apparatus.—19,288. M. Green, 25, Wakehurst Road, New Wandsworth, S.W. This invention, the object of which is to facilitate the raising of heavy lamp columns, pillars, &c., consists in combining a shear legs with a pair of wheels.

The following specifications were published on Saturday last, and are open to opposition until July 1st. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—3,559, Judge & Garrett, self-closing taps for valves. 7,406, Trier, machinery for surfacing, moulding and turning stone. 7,463, Spray, mantelpieces. 7,690, Carstensen, braces or drills. 7,815, Thom & McCall, windows. 7,834, Cameron, Commin & Martin, automatic apparatus for regulating the working of sewage filters. 9,799, Aveyard, Coveney & Coveney, locks or latches. 10,320, Jones, stone-dressing machines. 10,426, Garside, Carter & Hydraulic Engineering Co., electric safety appliances for lifts. 10,440, Whitton, window frames. 10,714, Read, drain pipes, &c. 11,321, White, apparatus for opening and closing windows, fanlights, &c. 11,376, Chandler, bricks, tiles, &c. 11,403, Dobbie, manufacture and fixing of tiles to walls, ceilings, &c. 11,543, Dennis, metallic hearth-plates. 11,569, Pullan & Mann, brick-moulding machinery. 11,632, Adams, sewage screens. 11,693, Cadman, tops for ventilating shafts. 11,696, McIntyre, automatic fire shutter. 13,755, Müller, siphon-flushing cisterns and fittings. 18,400, Woods, wall, ceiling and other tiles. 18,401, Woods, damp-courses. 20,639, Dunkelberg, manufacture of artificial stone.

1901.—2,446, Haerst, street-sweeper and scraper. 3,116, Haddan (*Sparrow*), joints for window-blind rollers. 3,788, Forster, vices. 5,157, Jumeau, ornamental panels for glazed windows. 5,319, Campbell, sash pulleys. 5,534, Lübbert, locks. 5,584, Boult (*Ledermann*), securing handles to door-locks, &c. 5,756, Price, iron inspection and manhole chambers for drains and sewers. 5,815, Brice, building bricks or blocks.

A New Theatre at York.—The plans for the new theatre in Clifford Street, York, on the site of the Corn Exchange, prepared by Mr. John P. Briggs, of Effingham House, Arundel Street, Strand, W.C., have been approved by the City Council.

SETTING OUT LAND.

By G. A. T. MIDDLETON.

A SURVEYOR is as frequently called upon to set out the lines of new roads, railways, canals, &c., on the land according to a predetermined plan, as he is to make a survey and plot the result. One operation is but the converse of the other, and yet it is more difficult to set out than to survey accurately.

As in surveying, it is possible to work entirely with the chain so long as the ground is fairly open and fairly level, but a theodolite or some other angle-measuring instrument becomes a necessity (if accuracy is to be secured) if there be many or serious obstructions, or if the ground be hilly.

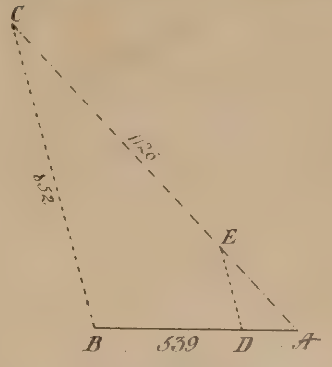
Usually the main points and centre lines are laid down first, their positions having been previously determined on the plan, and strong stakes being driven in where they occur; and it is well to use stakes which are distinctively coloured and numbered or lettered. Thus, bright red, blue and white stakes are admissible on grass land, one colour being kept for, say, junctions of centre lines, another for intermediate points on centre lines, and another for boundary lines of roads, while possibly even a fourth colour may be needed for boundary lines of building plots. As each stake is driven, it should be numbered or lettered, and its position on the plan similarly indicated.

Of the various problems which confront a surveyor when engaged in setting out, one of the easiest and most common is that of joining two ascertained points by a straight line. So long as the line is a short one, on evenly rising or falling ground and without obstructions, this can be done by erecting poles at each of the extremes and "boning" between them; that is, setting up a series of intermediate poles by sighting from one to the other. Simple as this seems, however, work done in this way is rarely accurate, for poles are not always held vertically, and land is rarely level; and a very slight hill or depression between the two extremities will introduce an element of probable inaccuracy.

If it be possible to see the foot of one pole from the other, it is best to erect a theodolite over this other, direct it towards the foot of the first pole where it is seen to enter the ground, level and clamp the horizontal limb, adjust with the horizontal tangent (whether main or vernier tangent does not matter), and then, allowing the vertical limb to swing, fix intermediate points one after another with the cross hairs.

If, however, there be rising ground between the two points, so that only the top of a long pole erected at the first station can be seen from the theodolite placed over the second, this pole top, swinging about in the wind, cannot be depended upon for accurately determining the point at its foot. In such a case a single intermediate station should be determined with the theodolite as nearly as may be in the true line and on the brow of the hill, and the theodolite should be shifted and erected over this new station. On being levelled, the cross hairs should first be directed on to the first station, and then the telescope swung right over vertically, if it be a traverse instrument, or the vernier plate revolved 180 degs. if it be a plain theodolite; when the hairs ought to exactly cover the second station. If not, as is probable, the instrument will have to be slightly moved to right or left until the correct position be found; and as the correction is generally a small one, an instrument having a sliding base plate is a convenient one to use. Once the position on the brow of the hill has been found, other intermediates are readily laid down accurately from it as before, by observations with the vertically swinging telescope.

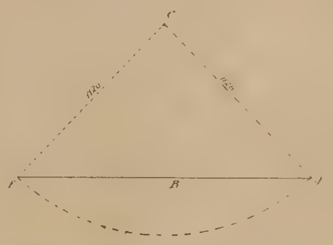
But more often than not it is impossible with a line of any considerable length, to see one extremity of it from the other extremity, and it becomes necessary to set out accurately the angle which this line makes with some previously determined line. This can be done, though with only approximate accuracy, by proportional measurements, as shown in the accompanying illustration, where it is assumed that a line A C has to be set out, the line A B being known. It is found by scaling that A C = 1126 links, A B = 539 links, and B C = 852 links. If each of these be divided by the same number, the sides of a small triangle proportional to A B C in every respect, and having the same angles, will be found. If a division of 20 be used, the proportional sides become 56·3, 26·95 and 42·6 links respectively. Lay down from A to D a length of 26·95 links. (Note that the diagram is only a diagram and not to scale, and that it would be very difficult on ordinary land to measure a distance accurately to so small a fraction of a link). Now, if 56·3 and 42·6 links be summed, it will be found that a line 98·9 links in length, with its extremities held at A and D, and with a point distant 56·3 links from A drawn out taut, will form the two lines A E and E D on the ground.



SETTING OUT AN ANGLE BY PROPORTIONAL MEASUREMENTS.

A E should, theoretically, give the direction of the line A C; but the accuracy of work done on this principle is very questionable indeed. A small error of some sort is sure to occur, even with the exercise of the utmost care, and if the line A E be not laid down in *exactly* the right direction, the point C will be missed on its prolongation.

It is much better to determine the angle C A B, and to lay this out with the aid of the theodolite. The angle is most readily found by striking a segment of a circle from the centre C on plan at the distance C A till the line A B is again met at F. Then half the chord A F (which can be ascertained by scaling), divided by 1126 (the length of A C), is the cosine of the angle C A B. In other words,



DETERMINATION OF ANGLE C A B.

$$\cos CAB = \frac{AF}{2} \div 1126$$

and therefore, $L \cos CAB - 10 = \log. \frac{AF}{2} - \log. 1126.$

From either of these equations it is easy to find the angle C A B, by using the tables of natural or of logarithmic cosines respectively.

The old Red Hall at Bourne, Lincolnshire, where the Gunpowder Plot was hatched, is threatened with destruction. The hall is the property of the Great Northern Railway Company, and is now used as the railway station-master's house. But the company are intending to pull it down unless some arrangement can be made to prevent its destruction, which, from an archæological point of view, would be a great loss to the county. The British Archæological Society are interesting themselves in the matter, and have approached the Kesteven County Council on the subject, but without result. Some time ago the company proposed to demolish the old Red Hall, but refrained from doing so on a petition from the inhabitants of Bourne.

Law Cases.

Architects' Fees.—The case of *Paget* v. *Dollar* was heard in the King's Bench Division of the High Court of Justice recently. This was a claim to recover damages for negligence, which was denied. Mr. Walton stated that in March, 1897, the plaintiff, Major Paget, who is now in South Africa, employed the defendant, an architect, to prepare plans for certain flats at Church Row, Hampstead. The plans were prepared, and a tender was accepted in March, 1898, for erecting the flats. The defendant then requested an increase in his fees, which was refused. It was then agreed that the defendant should hand over the plans for the sum of £504, then paid to him, and withdraw from the work. It was assumed and understood by the plaintiff that the necessary consent of the County Council had been obtained. It transpired that this was not so. The building line was found to be in advance of the general building line of the street, and to a large extent new plans had to be prepared before the consent of the Council could be obtained. This caused additional expense and a delay of several months. The defendant should first have obtained the consent of the Council, and not merely the district architect's approval. For the defence a large number of eminent architects were called. They stated that the defendant had followed the usual custom, and had done all that prudence would suggest; it was not always wise to anticipate the Council's objections. Mr. Justice Wright gave judgment for the defendant, with costs.

Negligence in Making Valuation.—On May 10th Mr. Justice Bruce delivered judgment in the King's Bench Division of the High Court of Justice in the case of *Harding* v. *Ewing* (reported on page 284 of our last issue). This was an action brought by Mr. Solomon Harding, secretary to a building society at Chester, against Mr. Charles Anthony Ewing, architect and surveyor, also of Chester, to recover damages for alleged negligence in making a valuation of four houses in Ailsa Road, Liscard, near Birkenhead. After reviewing the evidence his Lordship gave judgment for the plaintiff for £427 4s. 8d., with costs.

Agreements restraining Architects from Practising: A Curious Case.—In the Chancery Division of the High Court of Justice last week a motion in *Portsmouth* v. *Seward* came on for hearing. The plaintiff asked by his motion that the defendant, Edwin Seward, might be restrained from practising as an architect and surveyor, and from opening or encouraging any person to open an office for carrying on the practice of an architect and surveyor, in Swansea. It was stated in support of the plaintiff's case that, notwithstanding his undertaking, the defendant had, on the invitation of the Swansea Harbour Trustees, sent in plans, which had been accepted, for the erection of new offices at Swansea, and that he had accepted the position of architect for the new offices. This, the plaintiff's counsel contended, was practising in Swansea, and was in contravention of an agreement which had been entered into between him and the plaintiff. Defendant's counsel urged that there had been no breach of agreement, and that the defendant had simply, in answer to an advertisement by the Swansea Harbour Trustees, sent in his plans, which had been accepted, and that he was entitled to act as architect of the buildings in question, because by the agreement he had reserved his right to act in Swansea whenever called upon or specially invited to do so. Mr. Justice Kekewich held that the fact of entering the competition, and the preparation of the plans, was no breach of the agreement, and that Mr. Seward was entitled to this much; but he decided that if Mr. Seward superintended the erection of the buildings he would be practising in Swansea, and that he should be restrained from doing so. The injunction was suspended pending appeal.

A Stone-sawyer's Claim.—The case of *Perry* v. *Clements* was heard last week in the King's Bench Division of the High Court of Justice. Plaintiff was a stone-sawyer in the employ of Messrs. Jones Brothers, builders. On March 12th last year he was working on some ground in the neighbourhood of Addison Road, Kensington, where his employers were erecting some large flats. The defendant was a contractor at Hammersmith, and his carts came from time to time to the yard to shoot some material which was used in the mortar. On the day in question one of the defendant's carts having entered the yard and shot its contents, the carman began whipping up the horse, and the plaintiff, who was standing by, said, "If you continue to do that we shall have an accident." The driver, however, took no notice, with the result that the cart struck against a large slab of stone which weighed 15 cwt., and knocked it over upon the plaintiff. He was seriously injured, both his legs being broken, and he remained in the West London Hospital for fourteen weeks, and even now could only walk with the aid of a stick. The defence was that the carman was not really in the employ of the defendant when the accident happened, and that therefore he was not liable. The jury found that there was negligence on the part of the carman, who at the time of the accident was in the defendant's employ, and they gave a verdict for the plaintiff for £225.

Alterations at Gaddesby Hall: The Architect's Account.—The case of *West* v. *Barclay* was heard last week in the King's Bench Division of the High Court. The plaintiff is an architect practising in the West End of London, and the defendant a private gentleman of considerable means, who employed the plaintiff in connection with some works at Gaddesby Hall, Leicestershire. The action was brought to recover remuneration for professional work done in and about the estate. The work, which lasted from June, 1898, to October, 1899, about fifteen months, consisted in building a new wing, new stabling, repairs and alterations to the house, &c., and ultimately the cost came to over £14,000. The question was what was the fair remuneration to be paid to the architect under the special circumstances of the case, because it was not the ordinary case of an architect superintending the work for an employer where a builder was employed. Here was what gave rise to the difficulty. The dispute was whether plaintiff was to be limited to the ordinary charge of 5 per cent., or whether he was justified in making an extra charge of 5 per cent. considering the extraordinary nature of the work he did. If only 5 per cent. were allowed, then there were other expenses which would be due for out-of-pocket and travelling expenses, &c., and which defendant did not dispute; but if 10 per cent. were allowed, the question might arise whether that would not cover all expenses. The plaintiff's claim was that he was entitled to 10 per cent., on the ground that he had an agreement with the defendant by which he was to keep and pass the accounts, and to act as builder and contractor as well as architect, and the value of these additional services he put at 5 per cent. The defendant admitted that there was such an agreement, but alleged that 5 per cent. was sufficient to cover the plaintiff's services in every respect. Two architects of experience gave evidence for the defendant that the plaintiff's services would be fairly remunerated at 5 per cent. on the total outlay. Mr. Gruning, vice-president of the Royal Institute of British Architects, said he thought plaintiff had not done enough to entitle him to 10 per cent.; 5 per cent. all round would be the proper remuneration. His Lordship (Justice Kennedy) said a great deal of annoyance and inconvenience would have been saved if both parties at the outset here had put down their bargain in black and white and in plain language. It seemed to him that the plaintiff's claim as a whole was untenable, but he had come to the conclusion that the work as done was more onerous, both in point of responsibility and in the actual labour, than the usual course taken by architects working on the ordinary 5 per cent. scale. He thought plaintiff was clearly entitled to something over 5 per cent., and, taking everything into consideration, he held that plaintiff was entitled to 7½ per cent., with the exception of certain specified small items, and in addition he was entitled to certain expenses which were admitted. Judgment was entered for the plaintiff on the claim for £1,150, with costs, and for the defendant on the counter-claim for £107, with costs.

The New Bridge at Vauxhall.—An appeal case was heard before the Lord Chief Justice on Friday last in which the plaintiffs were Messrs. Pethick Brothers, builders and contractors, who are engaged in building the new bridge across the Thames at Vauxhall. They brought the action to recover the damage which they had sustained through a collision between a barge in tow of the defendants' steam-tug "Frank" and one of the abutments of the new bridge, owing, as the plaintiffs alleged, to the negligent navigation of the defendants' tug. The court dismissed the appeal. The Lord Chief Justice said that, by statute, the plaintiffs were bound to have three openings, each 70ft. wide. The opening through which the tug tried to go was only 64ft. wide. He was unable to come to the conclusion that the narrowing of the waterway did not contribute to the collision. He was not sure that, if the waterway had been 6ft. wider, the barge would have struck the dolphin at all. The plaintiffs, therefore, could not recover. The Master of the Rolls and Lord Justice Romer delivered judgment to the same effect.

The "Tube" Vibration Again.—On Thursday last, at the Surveyors' Institution, Great George Street, S.W., Mr. Daniel Watney, sitting as sole arbitrator, heard the case of *Pearce* v. *Central London Railway Co.*, a claim for compensation in respect of certain damage to the vicarage of Christ Church, Newgate Street, alleged to have been caused by the construction of the new line. Mr. Richard Philip Day, diocesan surveyor for London and Canterbury, said that in 1895 the vicarage was put in thorough repair. In January, 1897, cracks appeared and developed rapidly. In his opinion these were due to subsidence caused by the pumping operation. The damage became so serious that at one time he was afraid the property would have to be condemned under the London Building Act. He estimated the cost of repair at £750. Mr. Mott, one of the engineers to the railway company, said he failed to see how the pumping operations could possibly affect the vicarage, as no gravel—only water—was abstracted. In his opinion the cracks already existed, and had been pointed over. Mr. Alexander R. Sterring expressed his opinion that the cracks were certainly not due to subsidence. The necessary repairs could be executed at a cost of £35. This view was supported by other witnesses. The arbitrator reserved his award.

HOME ARTS AND INDUSTRIES.

THE Home Arts and Industries Association held the annual exhibition of work done in its classes on Thursday, Friday, Saturday and Monday last in the Gallery of the Royal Albert Hall. This Association is doing excellent work in its endeavour to encourage arts and crafts in the village, and to prevent in some measure the wholesale removal of industries to manufacturing centres. It is lamentable that so many local crafts should have already died out under the stress of modern trade and social conditions, and therefore this worthy endeavour of the Association is deserving of every support. The exhibits were of a most complete character; they included wood-carving, cabinet work, inlaying, repoussé and wrought metal work, pottery, leather work, book-binding, baskets, hand-spun woollen and linen fabrics, lace, embroidery, tapestry, carpets. Mrs. G. F. Watts's classes at Compton and Aldourie showed examples of their excellent terra-cotta work, pottery and a wrought-iron gate. The Aldeburgh and British and Irish Spinning Weaving and Lace School classes showed some tapestry work, but were somewhat indicative of what this should not be, in the endeavour to obtain pictorial representation and elaborate designs; this treatment is not adapted to work that grows up on the loom, as it shows at once that a design has been carefully prearranged. At the Altrincham and Welbeck stalls wood-carving from designs by Mr. J. Phillips was especially noticeable. The Ascot class showed cabinet work, small tables, carved wooden picture frames and inlay. Wood-carving was also exhibited at the Southwold stall. Mr. Harold Rathbone's developed industry at Birkenhead had a large exhibit of Della Robbia pottery, and the Birmingham class showed some mats of rich and harmonious colour. The Keswick class showed good repoussé copper work, silver cups and copper pots. The other examples of repoussé work in the hall were too overstrained for effect, and were hard on the material. The Ruskin Linen Industry exhibited some beautiful examples of embroidered and worked altar cloths, &c. The Brabazon Employment Society are employing disabled soldiers and sailors profitably and pleasurably. It will be seen that architects and others engaged in church work and interior decoration should avail themselves largely of this Association in order to obtain craft work which is always interesting and often excellent.

Masters and Men.

A Strike of Bricklayers at York has occurred against an alteration of working rules proposed by the masters. Over 200 men are affected.

A Joiners' Strike at Teeside, that is, in Stockton, Thornaby, Middlesbrough and the Hartlepools, has occurred for an increase of wages from 9d. to 9½d. per hour. About 600 men are out.

A Strike at Nuneaton of the carpenters and joiners is in progress for an increase of ½d. per hour on the present rate of 8d. The masters have issued notices that the wages will be reduced to 7½d. per hour.

At the Penrhyn Slate Quarries all the mechanics have signed for the resumption of work, and it is expected that this week at least a thousand quarrymen will be at work. Last week eighteen officials, at the command of Lord Penrhyn, worked as quarrymen and labourers in the "Lady Gallery," the most profitable and easily worked.

The Strike of Swansea Builders' Labourers for an extra ½d. per hour is gradually affecting the whole of the building trade. The carpenters, joiners, plumbers, painters, plasterers, &c. associated with the Federated Trades have decided to cease work in the event of the demand not being conceded. Between 300 and 400 men will be affected by this decision. The hauliers have decided to come out at once, and some thirty men belonging to the Stonemasons' Union ceased work some days ago.

Wages in Australia.—In Australia, as in older countries, skilled labour usually commands a maximum wage, its value being enhanced by the general adoption of the eight-hour system in most of the various branches of industrial activity. In New South Wales the average rates per week enjoyed in the engineering trades are as follows: Bench hands, 41s. 6d.; blacksmiths, 55s. 6d.; brass-finishers, 45s.; brass-finishers' foremen, 80s.; coppersmiths, 49s. 6d.; engineers, 54s. 3d.; fitters and turners, 53s. 6d.; frame-saw hands, 43s.; labourers, 35s.; machinists, 46s.; moulders, 52s. 9d.; painters, 44s.; pattern-makers, 59s. In the ornamental zinc manufacture the rates are: Blacksmiths, 48s. to 54s.; brass finishers, 50s. to 60s.; metal workers, 48s. to 78s.; zinc moulders, 20s. to 44s.; foremen, 80s. to 100s. In other metal works general hands obtain from 42s. to 50s.; machinists, from 40s. to 50s.; and scale makers, from 20s. to 50s. In other trades the rates are: Gas-fitters, 25s. to 60s.; galvanised iron workers, 42s. to 54s.; plumbers, 35s. to 85s. 6d.; oven makers, 40s. to 50s.; stove makers and fitters, 30s. to 72s. In hydraulic engineering blacksmiths get from 42s. to 63s.; draftsmen, 60s. to 90s.; fitters, 54s. to 62s.; hammer men, 40s.; pattern makers, 60s. to 63s.; and turners, from 48s. to 60s. In lead mills the rates are: Moulders, 42s. to 60s.; millers, 42s. to 48s.; rollers, 25s. to 57s. 6d.; and foremen, 67s. 6d.

The Central School of Arts and Crafts.—The Technical Education Board of the London County Council will shortly submit for the approval of the Council a scheme for purchasing as a site for the erection of new buildings as a permanent home for the Central School of Arts and Crafts, at present existing at 316, Regent Street, certain premises acquired by the Council in connection with the Southampton Row widening at the corner of Orange Street and Southampton Row. It is also intended that accommodation shall be found on the site for the London County Council School of Photo-Engraving and Lithography, in the event of that school being unable to continue the tenancy of its present premises. The cost of the site is stated to be £45,000, which sum it is proposed shall be borrowed under the authority of the Technical Instruction Acts.

Builders' Notes.

A New Test for Portland Cement.—Mr. A. Patchett writes to correct an error in his communication under this heading on p. 269 of our issue for May 8th inst. For "grains" read "grammes."

Stables.—His Majesty's Office of Works have entrusted the St. Pancras Iron Works Co., Ltd., with the fitting up of the stables at the British Embassy in Paris. Among other stables which this old established firm have fitted this year are those of Lord Durham at Newmarket, The Countess of Lovelace, Sir Audley Neeld, Sir William Marling, The Hon. W. F. D. Smith, M.P., Mr. F. Layland Barrett, M.P., Mr. E. J. Stanley, M.P., and Mr. W. S. Cunard.

New Fire Prevention Testing Station.—The executive of the British Fire Prevention Committee announce that the opening of their new testing station at Westbourne Lodge, Bayswater, which had to be postponed on account of the illness of their chairman, Mr. Edwin O. Sachs, will now take place on Wednesday afternoon, the 22nd inst., when testing operations will be resumed and the issue of the Committee's reports, which have already reached an aggregate of sixty, will again be regularly proceeded with.

Hull Official Receiver and Speculative Builders.—A meeting of the creditors of Alfred John Wiles, 80, Newland Avenue, and Fred Hunter, 23, Reynoldson Street (trading as Wiles & Hunter, builders, De Grey Street, Hull), was held recently at Hull. The gross liabilities were stated at £6,988 14s. 7d., but the nett liabilities were put at £482 3s. 2d., and the assets at £469 18s. 7d., leaving a deficiency of £12s. 4s. 7d. The debtors attributed their insolvency to want of capital, too much on hand at once and high prices of materials and labour. The Official Receiver (Mr. Maples), who had obtained an order for a summary administration of the estate, said that most of the properties had three charges upon them, and it was doubtful whether there would be any surplus whatever. Things were getting to such a pitch with speculative builders that he did not know how they managed to get any credit at all. Things were getting worse and worse, and something would have to be done. He thought the matter should be taken up by the Chamber of Commerce or the Incorporated Trades Society.

A Year's Building in Leeds.—The report of the Leeds Building Inspector (Mr. W. Towers) for the twelve months ending March 25th last shows that the year was a busy one in the building trade. The total number of plans submitted to the Building Plans Committee was 2,849, or 65 more than last year, and the total number sanctioned was 2,199—an increase of 30. But the number of buildings shown on the approved plans, 8,952, was 487 less than in the preceding twelve months. Of these buildings 2,947 (on 531 plans) were houses, and 1,807 mills, warehouses, stables, sheds and workshops; 2,427 represented additions and alterations, and 1,771 conveniences. In the previous year there were 3,549 houses and 2,039 mills, warehouses, stables, sheds and workshops. The 2,947 houses for the building of which authority was given comprised 19 villas, 88 semi-detached villas, 812 through houses, and 2,028 back-to-back houses. The latter figure is less than in the preceding year, when 2,300 back-to-back houses were sanctioned. The number of through houses is smaller by 285, and semi-detached villas less by 45, while the number of new detached villas for whose construction authority has been given is just the same as last year. During the past year 3,030 houses, including 2,035 back-to-back houses and 907 through houses) were completed and certified for occupation, a decrease of 29; while 1,591 miscellaneous buildings (including churches, chapels, schools, hotels and other institutions) have been so certified. The distribution of the newly-erected houses according to wards is interesting. The chief extensions have been in East Hunslet (427), North-East Ward (402), North (353), Headingley (324), Armley and Wortley (308), West Hunslet (268), Bramley (259) and East Ward (211). Holbeck accounts for exactly 200, followed by New Wortley with 137, and the North-West Ward with 122.

The Banking Premises of Messrs. Cocks Biddulph & Co. been added to have considerably from plans by Mr. J. Oldrid Scott, F.S.A., F.R.I.B.A. The additions are to be fireproof on the "Fawcett" system.

London County Council.—At last week's meeting the recommendation to hold a housing conference on June 28th at the County Hall, Spring Gardens, S.W., was agreed to. After a short discussion the Council decided that on account of the cost, amounting to £1,450, the request of certain petitioners for a horse-ride in Finsbury Park could not be acceded to. For some years past the Technical Education Board have been seeking suitable premises for the permanent accommodation of the Central School of Arts and Crafts, at present housed in premises in Regent Street. On November 8th, 1898, proposals were submitted to the Council for the acquisition of premises close to the present school, known as Oxford Mansions. The recommendation was postponed, and afterwards referred back. Next week a proposal will be submitted for the purchase of a site at the corner of Orange Street and Southampton Row at a cost of £45.000 for the erection of the school. The Board also propose to establish a day training college for teachers.

A New Dovetailed Brick.—Mr. P. Chick, of 121, Oakhill Road, Putney, is making a patent dovetailed recessed brick of novel form which provides improved means of fixing joiners' work, advertisement boards, &c., to brick walls. The course is laid with the recess in the brick upwards, a wood slip is then laid in this recess, either the whole length of the wall, or with a stretcher at intervals of 2ft. to 3ft. The next course is then laid, securely fixing the wood slip as a ground to be nailed to, and, projecting the thickness of the plaster, forms a guide to the plasterer. One course of bricks can also be used instead of two, or the wood slips extended to the depth of a brick or more to obtain a wider surface for fixing larger work. It is claimed that by the use of Chick's patent brick and wood slip a first-class job is obtained at a reduced price in consequence of the great saving effected in joiners' labour, first fixing being entirely dispensed with and the plasterer finishing his work ready for the joiner, who is able to fix his work quicker and better. For skirtings, dados, picture rails, panelled door casings, splayed linings, &c., the advantages are obvious, and better than the present method of plugging walls or fixing into breeze bricks. Chick's bricks are at present made in two qualities.

NEW WHARVES AT PLYMOUTH.

LAST August the Victoria Wharves and Pier at Cattedown were formerly opened by the then Mayor of Plymouth (Alderman J. Pethick). This event marked the beginning of a new and important phase of the development of the Cattewater. At that time, though the dock which forms one of the chief features of the undertaking was completed and ready for use, a good deal of constructive work remained to be done. Since then active progress has been made towards the completion of the wharves and buildings, and a clearer idea can now be formed of the magnitude of the undertaking, which owes its inception of execution entirely to the enterprise of Mr. C. L. Duke. Within the dock, which is 250ft. in length, there is a depth of 27ft. of water at low spring tides. This has been achieved by making the bottom of the dock lower than the bed of the harbour, enabling large vessels of heavy draught to lie afloat at all states of the tide. The dock has, indeed, a greater depth of water than any other quay, wharf or dock in the port. Since August the construction of a pier jutting out into the Cattewater has been commenced, and work upon it is now in full swing. Built of concrete, the pier will be 500ft. long and 50ft. broad, and on the east side will have a minimum depth of 27ft. of water at low tide. Besides affording additional shelter to the dock, the pier will, when completed, increase the deep-water wharfage to a length of 1,300ft. In addition the property includes other wharves with shallow water at low tide. At a cost of about £14,000, the Cattewater Commissioners are at present dredging the lower harbour to a uniform depth of 17ft. at low spring tides, and at his own expense Mr. Duke is deepening the approach to the Victoria Wharves to a similar depth. This will greatly facilitate traffic in the harbour and render access to the Victoria Wharves easier at all states of the tide. Attached to the wharves is a considerable extent of ground, and on the west side of the dock No. 1 warehouse, with a capacity of 16,000 superficial feet of floor space, has been completed, while No. 2 warehouse, with an area of 20,000ft. floor space, is rapidly approaching completion. Both these buildings are massive stone structures with concrete floors, provided with every convenience for the storage of merchandise. On the east side of the dock transit sheds are in course of erection, which will have a superficial floor space of 6,000ft. Other buildings for storage and transit will be erected as the traffic develops, and Mr. Duke has spare ground for the erection, if required, of warehouses with a total floor space of nearly five acres. More than a mile of railway sidings has been laid in the wharves, the track being laid with wood blocks, and both the Great Western and South Western Railway Companies have direct access to the dock. Steam cranes of the latest type have been provided for the rapid handling of cargoes, and these are to be supplemented shortly by hydraulic cranes, hoists, conveyers and capstans. It is anticipated that with the additional facilities now provided at Cattedown new trade will be attracted to the port.

Keystones.

The New Opera House, Bank Premises and Shops at Tunbridge Wells was commenced last week, Mr. John P. Briggs, of Arundel Street, Strand, who has prepared the designs, hopes to get the theatre portion of the scheme ready by Christmas.

Harding v. Ewing.—Messrs. Guy Ewing & Co., of 84, Mount Street, Park Lane, W., inform us that they have no connection whatever with the defendant in this case, which was reported on p. 284 of our last issue, the judgment being given on p. 299 of the present issue.

Maidstone's New Theatre.—At a recent meeting of the Maidstone Urban Council, plans of the new theatre in Brewer Street, prepared by Mr. John P. Briggs, architect, of Effingham House, Arundel Street, Strand, were approved. It is hoped to have the building completed by the autumn.

The New Joint Fever Hospital for Dumbarton, erected on a site at Havock, by the Western District Committee of the County Council of Dumbarton and Dumbarton Town Council, was opened recently. The site on which the hospital stands is in a commanding position overlooking the Clyde, and extends to nearly five acres. The buildings consist of administrative block, two pavilions (each of two wards), caretaker's house, &c. The original cost was estimated at £14,000, but this had been exceeded. The plans were prepared by Mr. John M. Crawford, architect, Dumbarton, and the work was carried out under the care of Mr. G. Roxburgh, inspector of works. The wards are capable of holding forty-four beds. The sewage is to be treated by means of the septic tank principle.

Architectural Association Day School: Appointment of Master.—The Committee invites applications from architects for the post of master in the day school about to be established at the Architectural Association. Particulars will be forwarded upon application to the secretary, 56, Great Marlborough Street, W. Arrangements have now been made to open a complete day course in October next, in addition to the present evening course, which will be continued as before. The advisory council in reference to these classes consists of the following gentlemen:—Professor Aitchison, Dr. Rowand Anderson, and Messrs. F. T. Baggallay, John Belcher, Hippolyte J. Blanc, J. M. Brydon, J. J. Burnet, W. D. Caröe, T. E. Collcut, Henry L. Florence, Ernest George, Henry T. Hare, T. G. Jackson, E. W. Mountford, Leonard Stokes, C. F. A. Voysey, Alfred Waterhouse and Aston Webb.

A New School at Edzell is to be erected from competitive plans by Mr. D. Wishart Galloway, architect, Brechin, at a cost of £2,000.

The Queen Victoria Memorial at Liverpool is to consist of a monument containing a statue of the late Queen. It is proposed to erect it on the vacant space lately occupied by St. George's Church.

The "Oxford" Wing of Welbeck Abbey, which was so much damaged by fire last October, has been demolished to make way for an entirely new wing. The alteration will also involve the destruction of the covered tan gallop, one of the sights of Welbeck.

Workmen's Dwellings at West Ham.—The West Ham Corporation have in hand a scheme for erecting workmen's dwellings (double tenement) on the Manor Road and Temple Mills estates. The houses are estimated to cost £133,296. The rentals for the double tenements will range between 12s. and 12s. 9d. per week, and the houses will be fitted with all modern conveniences, including the electric light.

A New Forward Movement Hall at Newport, Mon., has been erected in Corporation Road in the Renaissance style of architecture from the plans of Messrs. Habershon, Fawckner & Groves, at a cost of £2,700. The building, which is of red brick with freestone dressings, has accommodation for 800 persons, and is provided with classrooms and vestries and numerous exits. Mr. D. Jones, of Newport, was the builder.

Stonehenge will soon be shut off from the public by a wire fence, which Sir Edmund Antrobus, the owner of the portion of Salisbury Plain on which the monument stands, is having erected round the stones. The "Salisbury Times" learns that on and from the 24th inst. a charge of 1s. will be made to visitors who may desire to pass this barrier and get a near view of the monument.

York Architectural Society.—A general meeting of the members of this society was held recently, at which the officers to serve on the executive were chosen. In the unavoidable absence of the president, Mr. William Bell, the chair was occupied by Mr. C. H. Channon, Malton. Regret was expressed at the retirement of the hon. secretary, and a special vote of thanks was passed to Mr. Burleigh for the manner in which he had filled that office for the past ten years. Mr. Channon was unanimously elected president, and also represents the York Society on the Council of the Royal Institute of British Architects, London. The vice-presidents chosen were Mr. A. B. Burleigh and Mr. E. T. Felgate. Mr. Thomas Monkman accepted the office of hon. treasurer, and also acts as a trustee of the society. Mr. George Benson was elected as hon. secretary, and the following gentlemen were selected to serve on the committee, viz.: Messrs. J. Brett, jun., S. R. Kirby, S. Needham, A. J. Penty and F. Raney. Mr. S. G. Highmoor was re-elected librarian, and Messrs. E. A. Poland and A. J. Toomer auditors for the current year.

West Malling Church.—The nave of St. Mary's Church, West Malling, is being rebuilt by Messrs. G. E. Wallis & Sons, of Maidstone, from the designs of Mr. J. T. Micklethwaite, F.S.A., at a cost of £4,700. The nave will contain two side aisles, with a saddle roof, and light will be admitted through clerestory windows, while heat will be diffused by means of hot water coils. The walls will be erected on the same foundations as the thirteenth-century nave. In the eleventh century a Norman church was built (possibly taking the place of the old Saxon one) after the type of those common in the district, and in the fourteenth century the stone for the enlargement of the old Norman nave by the addition of two aisles with other improvements was laid. Then as the centuries went on the building failed, and the historian Hasted, writing in 1779, recorded that the chancel and steeple were then standing but that the nave had fallen down in 1778. A brief was obtained in 1779 to raise money over England for £2,129, which was needed for the rebuilding, completed in 1781. Thus, in 1780, there must have been a third stone-laying to rebuild the nave. At first it was proposed in the present restoration to make the Georgian nave as suitable as might be, but eventually it was decided to rebuild the nave entirely.

An Infectious Diseases Hospital is to be erected by the Llanelly Borough Council on a site at Machynis, at an estimated cost of £5,000.

New London and South Western Bank Buildings have been erected at the corner of Plashet Lane and Gipsy Lane, East Ham, by Mr. James W. Jerram, from designs by Mr. J. H. Carte. The style of architecture is chiefly Venetian, with a Byzantine cupola. The materials used are terra-cotta and Ruabon bricks, supplied by Messrs. Edwards, of Ruabon.

Six Cottage-Homes for the Gateshead Board of Guardians, each to accommodate fifteen pauper children under a foster-mother, were recently opened. They have been erected in the Derwent Valley, at a cost of £15,000. There are workshops in connection with the buildings where the boys and girls may be initiated in useful trades.

Over the late Professor Max Müller's Grave in Holywell Churchyard, Oxford, a tall Celtic cross, standing some 10ft. high, has been placed. It is in grey West-country granite, and has been practically designed by the late Professor's widow, whose original sketch has been carried out by Messrs. Harry Hems & Sons, ecclesiastical sculptors, of Exeter.

A Useful Map.—We have had an opportunity of testing the new three miles to the inch map of England issued by Messrs. Keith Johnston, Ltd., of Edinburgh and London, uniform with their map of Scotland, and find it accurate, clear and trustworthy. In the printing, black ink is used for the towns, &c., with brown for the hill names and blue for water, whether river, firth, or lake. To cyclists it will be most useful, the roads being clearly indicated. Messrs. Keith Johnston undertake special map work, and are prepared to supply a map of any particular district having just such features marked as may be required. The series of maps and atlases issued by the firm should be remembered when selecting a map either for professional work or holiday purposes.

Architectural Association.—The officers and committee for the session 1901–1902 have been elected.—They are as follows: President, Mr. W. Howard Seth-Smith; vice-presidents, Messrs. G. B. Carvill and E. Guy Dawber; hon. treasurer, Mr. Francis Hooper; hon. librarian, Mr. F. J. Osborne Smith; hon secretaries, Messrs. R. S. Balfour and H. P. G. Maule: committee, the foregoing gentlemen and Messrs. A. T. Bolton, F. D. Clapham, W. A. Forsyth, H. T. Hare, Hon. A. McGarell Hogg, Arnold Mitchell, W. A. Pite, G. H. Fellowes Prynne, W. H. Raffles and E. Howley Sim; hon. solicitor, Mr. W. H. Jamieson; hon. assistant librarians, Messrs. C. H. F. Comyn and W. A. Jeckells; hon. auditors, Messrs. E. Greenop and Guy M. Nicholson; and secretary and registrar, Mr. D. G. Driver.

"The Craftsmen's Club."—A club under this title, open to all respectable men skilled or interested in any art or craft, was founded at a meeting held at Birmingham on the 26th March, 1901, to invite applications from anyone interested in this movement. The objects of the club are to enable readers of various technical papers to meet personally, to form a library to facilitate the acquisition of information in case of minor technical difficulties, in perfecting and finishing work of different sorts, to encourage the undertaking of useful hobbies, to lessen their expense and to increase their usefulness. Lectures and demonstrations are to be encouraged and an effort made to take premises for the sale of work done by members. Full reports of proceedings will be obtainable, representatives are to be appointed in various towns and a staff of experts and advisers appointed as the club developes. It is claimed, that while the general idea of such a club is not new, there is a novelty in its method of seeking a common basis for active results, and the utmost precautions are being adopted to build up the club on good economical and financial principles. No dividend is to be payable. One-third of the subscriptions is to be devoted to reserve and to revert to charity if the club dissolve. A trial set of rules, prospectus, &c., have been typewritten, and a copy will be sent to applicants who care to enclose 6d. for the same to Mr. W. Moseley, secretary, 319, Broad Street, Birmingham.

The New Petit Theatre has been opened in the Boulevard de Clichy, Paris.

Alterations at Aberystwyth Town Hall at a cost of £6,000 formed the subject of a Local Government Board enquiry recently.

A New Church Mission Room at Churwell is being erected. The building will be in the Early English style of architecture, and provide accommodation for 300 worshippers. The cost, exclusive of the site, will be £1,250.

A New Church at Grove, near Wantage, has been erected at a cost of £2,000. The pulpit, which has been removed from the old church, was first occupied by Dr. Pusey at the opening of the church in the year 1837. The font, too, which originally came from Pusey, near Faringdon, Berks, is the one at which Dr. Pusey was baptized.

Duchess of Teck Memorial.—A drinking fountain, erected in memory of the late Princess Mary Adelaide, Duchess of Teck, was unveiled at Richmond last week. The fountain, which is of polished red granite, immediately adjoins the Richmond Park entrance on Richmond Hill, and is of ornate design. Attached are four bronze plaques, the principal consisting of a lifelike bust of the late Duchess. Mr. F. J. Williamson was the sculptor.

A New Town Hall at Marlborough is being erected of brick and stone, with red tiles. Its accommodation includes a session court and council chamber on the ground floor, and a large assembly room on the floor above, adaptable for the second court at quarter sessions. In the basement are cells, warders' lobbies, lavatories and a muniment room. The contract price is £7,270.

A Scholarship of £25 for one year is offered by the Worshipful Company of Coach Makers and Coach Harness Makers of London, in connection with the higher technical day class in Road Carriage Building at the Polytechnic carriage building schools, Balderton Street, Oxford Street, London W., commencing Monday, September 30th, 1901. Conditions, and forms of application to be filled in by candidates desiring to compete for the scholarship, can be obtained by applying to the Clerk to the Company, Coachmakers' Hall, Noble Street, E.C., or 8, Lincoln's Inn Fields, W.C. The forms must be returned to the Clerk on or before July 3rd next.

Hyde Abbey, Winchester.—It is to be hoped that the Hants County Council will acquire for the public, as a memorial to King Alfred, the site and remains of old Hyde Abbey, the burialplace of the great king and his wife Alswitha. Founded originally by King Alfred as a monastic house, it was finished after his death by his son, Edward the Elder. Despoiled by William the Conqueror because some of the choir fought with Harold at the battle of Hastings, a portion of its lands were afterwards restored. A century later a new church and monastery were built by Henry I. on what was known as the Hyde Mede. Burnt down in 1140, it was rebuilt by Henry II. in 1182, from which time it flourished till the era of the Dissolution, when the Abbey was surrendered to Henry VIII., and soon afterwards pulled down, the site being granted to Richard Bethel. Not much is now left.

The New Walton and Kirkdale Technical Institute has now been completed. It has cost £8,500, exclusive of scientific fittings, &c., and is situated at the corner of Carisbrooke Road and Harlech Street. The style of architecture chosen by the Corporation surveyor, Mr. T. Shelmerdine, from whose plans the pile has been reared, has been the English Renaissance, and the structure is built of red wire-cut Ruabon bricks, with Grinshill stone heads and dressings, the roof being of Velinheli slates. The main frontage, which is in Carisbrooke Road, has a length of 126ft., the elevation in Harlech Street covering a length of 65ft. The principal entrance is from Carisbrooke Road, which opens into a vestibule and hall, and there is a staircase to the upper floor and to the basement, and the corridors leading to the various class-rooms are ample in their width. On the ground floor there are five class-rooms, all of large size. In the basement two class-rooms have been arranged, whilst on the first floor there are three class-rooms and an examination and lecture hall 52ft. by 34ft.

THE ROYAL OPERA HOUSE, COVENT GARDEN.

Some Particulars of the Alterations made by Edwin O. Sachs, Architect.

THE alterations which have been carried out at the Royal Opera House at Covent Garden, under the direction of Mr. Edwin O. Sachs, may be divided into three groups: (1) Structural alterations for the audience, (2) structural alterations for the management, (3) and equipment of the stage.

Structural Alterations for the Audience.

These comprise the re-modelling of the exit and entrance arrangements of the stage and the provision of a special stalls corridor, so that the stalls, with their corridors, now form an independent whole, having their own conveniences, cloak rooms, &c., and do not, as formerly, have to encroach upon the accommodation of the pit-tier boxes or the entrances and exits of other parts of the house.

Entering from the main vestibule, there are now two sets of swing doors into the stalls corridor. From this corridor there is a central entrance into the stalls, and one on either side (right and left). There are pass staircases from the other tiers to the stalls corridors, and a special extra exit to Floral Street. It is needless to say that the rearrangement of entrances and exits to the stalls is of considerable importance in case of panic or fire, quite irrespective of their general convenience.

In connection with the stalls alteration, the old-fashioned front and apron of the stage, which used to protrude into the auditorium, has been abolished, and the orchestra set closer to the curtain line. This considerably affects the lighting arrangements of the stage and brings the "picture" more in accordance with modern ideas. It also leads to the arrangement of extra rows of stalls. Two new boxes have also been formed in place of the old entrance to the stalls from the pit box tier. A number of minor improvements have also been made in different parts of the house, although perhaps these do not call for any lengthy comment. The carriage approach from Bow Street has been improved by the formation of extra doors, so that two lines of cabs and carriages can now "set down" and "pick up."

Structural Alterations for the Management.

These alterations, at the back of the house, comprise quite a number of important items: an entire re-modelling of the storage and wardrobe arrangements, as well as the equipment of new workshops.

In the first place, the large property shop, which used to be over the auditorium, has been accommodated on a large additional floor, erected over the whole of the back wing of the building. This back wing has been re-modelled, and now contains fine suites of rehearsal rooms both for solo artistes, for the chorus and for the ballet, distributed on three floors, well lighted and aired, and equipped with all modern sanitary arrangements, an independent staircase, and an independent exit. The entire wardrobe, dressmaking and tailoring department has been housed on the south side of the stage, in suites of rooms comprising three upper floors, having two independent staircases and inter-communication by means of a hydraulic lift.

On the north side of the house a suite of one of the upper floors has been retained as an armoury, a second has been re-modelled for storage purposes, whilst a third now comprises a fine set of offices for the stage department. Here, again, an independent staircase connects the various floors, and inter-communication is also obtained by means of a new hydraulic lift.

Below the stage level on either side of the house the various suites of rooms have been remodelled and modernised as far as possible, one suite next to the stage entrance, for instance, comprising the offices of the firemen, stage mechanist and electrician, all in close proximity to one another and in close touch with the stage manager's offices by the independent staircase just mentioned, and with the stage by a pass stairs on the other. Even the stage door has been re-modelled, inasmuch as the doorkeeper's office now has a small waiting-room; and an entirely separate entrance, with timekeeper's office, has been formed for the working staff, by which means the crowding of the stage door will be reduced.

The back portion of the stage has been separated off from stage level downwards, with the object of forming a large scenery store built on fire-resisting lines, and equipped with all the necessary racks for holding the "cloths" used in the usual repertoire. Similarly, in the back wing, an old store, formerly known as the "Infirmary," has been enlarged and re-modelled, with the view of forming a "wing" store. In spite of these two modernised storage arrangements, the accommodation for scenery at Covent Garden is still necessarily of a very limited character compared with that of Continental houses, and must remain a source of constant anxiety and trouble to a management who produce an average repertoire of twenty-five operas in the short space of eleven weeks.

Equipment of the Stage.

We now come to the great alteration of the stage, an enormous undertaking at all times, but rendered particularly difficult owing to the short period available, the existence of a Ball Season during the major part of the winter, and the presence of an enormous stock of scenery, &c., which it would have been impossible to have moved out of the house except at a very great cost.

EDWIN O. SACHS, ARCHITECT.

The alteration of the stage comprised entire gutting from top to bottom, so that nothing of the old stage from "gridiron" to cellar remains, with a small exception of a couple of wood-fly galleries. Further, the alteration comprised the entire unroofing of the stage, raising the structure by 20ft., and re-roofing on modern lines. Further, it involved a considerable amount of excavation work, with a view of forming deep pits to take certain parts of the mechanism.

An entirely new "gridiron" had to be constructed right across the stage, two "gridiron" galleries had to be constructed on either side, and a number of light connecting ways running across the stage. An entirely new stage, including all construction parts, had to be provided, together with a "mezzanine" floor. The opening of the stage towards the auditorium had to be equipped with a fire-resisting curtain (the largest in London), and a strong party wall built from the stage level downwards into the cellar. In connection with this constructional work, the whole of the gridiron galleries, stage and mezzanine had to be re-floored, and the entire cellar or superficial area of the stage concreted over.

The scene docks on either side of the stage had to be remodelled; one of them, for instance, being equipped with a large scene door, with the revolving shutters, measuring 28ft. in height; another being provided with several floors to take planned scenery, such as rocks, groups, &c. The exit and entrance arrangements of the stage also had to be re-modelled in such a way as to allow of greater convenience, and for the greater safety of the employees in case of accident.

In connection with the constructional alteration of the stage, an entirely new stage equipment had to be provided on modern lines, everything above stage being now worked on the Brandt patent counterweight system, and everything below the stage on Sachs's patent electrical bridge system (see plan on the next page and illustrations in centre plates).

Without entering into detail, the stage may now be described as comprising a series of six horizontal sections running parallel with the curtain line from front to back, each section being 8ft. wide, and the whole being followed by a large back stage or rear stage. The first section contains nothing but a plain "carpet cut," and openings to take the old-fashioned "grave" trap, "star" trap or other similar contrivances. The second and third sections comprise large bridges, which can be raised 6ft. above the stage or lowered 8ft. below the stage, constructed in two levels: on the lower level appliances can be installed for the purposes of raising minor platforms above stage level, or sinking taps and the like. The fourth, fifth and sixth sections comprise large bridges running right across the stage front, which can be raised 9ft. above the stage or lowered 8ft. below. The back stage has no openings or mechanism beyond certain trap doors to a scenery store and the necessary electrical mechanism for raising and lowering scenery for storage purposes.

Between the various sections of the stage, long longitudinal flaps 2ft. wide have been formed, and these can be easily opened to allow scenery to be passed through below for transformation and similar scenes. Each section is equipped with what is termed a pair of chariots, to hold "wing" lights placed on so-called wing ladders. All the electrical bridges are worked from "mezzanine" level and from ordinary switch boards; they can be raised and lowered at various speeds and take loads up to two tons. They can also be moved without vibration or noise at a cost of about ¼ for power on a full rise when loaded.

Above the stage level, each section has its series of lines to take cloths, borders, &c. Each section has a batten, from which the electric battens are suspended; and each section has a large wooden lattice-girder, from which heavy pieces of scenery can be suspended. There are, on the average, about ten lines for ordinary battens, a girder batten and a light batten to each section; besides these lines, there are the equipments of flying apparatus and the like, whilst in front there are, of course, the necessary lines for tableaux curtains, act-drops and draperies.

Everything that is suspended from above can be worked at stage level, or at either of the gallery levels, every scene being counterweighted to a nicety; and one man can easily handle any scene. No mechanical contrivance is required, and in practice quite a number of scenes can be rapidly changed in a minimum of time.

Throughout the structure and mechanism steel has been used, iron pulleys and wire cable; and the inflammable materials have been absolutely reduced to the flooring of the gridiron and galleries, and the hardwood flooring of the stage and mezzanine. In other words, an absolute minimum of inflammable material replaces what was almost a maximum; and seeing that the electric light has been installed, the risk of an outbreak of fire or its spread has been materially reduced.

The arrangements for the electrical illumination of the stage had naturally to be remodelled and elaborated to meet the altered circumstances, the whole of the plant installed some two years back, of course, being re-used. Similarly, the steam appliances, telephone, speaking-tube and other minor technical installations to be found on a modern stage were re-modelled. The system of gas-lighting was entirely abolished, and, similarly, the system of limelight for special effects.

Programme of Work.

Regarding the programme under which the work was carried out, it would be well to remember that the Opera season of last year closed on August 3rd, 1900, and it required three or four weeks for the scenery to be cleared in the usual way. Work was, however, immediately commenced on the morning after closing, the first work comprising the alteration of the auditorium and formation of corridor already described, and the raising of the roof over the stage. The whole of the alterations were completed on October 1st, and the big roof alteration completed on October 8th.

It should be here remembered that the roof alteration comprised a span of 90ft. to a width of 70ft., at a height of 90ft. above the ground, without any facilities for storage accommodation in the vicinity; that the building had to be kept waterproof during the alteration; and that the stage hands and mechanists were working below whilst the alteration was going on above. The scaffolding arrangements alone were most complicated. A system of suspended scaffolding was applied, no vertical support being obtainable on the span of 90ft. When the roof was completed, the "gridiron" had to be laid in a similar way.

Contemporaneously with this alteration the big fire-resisting curtain was being fitted in the proscenium opening, and the walls between stage, cellar and auditorium being built. The curtain was put into position by October 15th, so that Mr. Rendle was able to take up the tenancy for his Ball season, and the first ball was actually given on October 26th. The big scene store at back of stage was taken in hand in September, and was completed by November 1st, 1900. The back wing alteration at the back was the last taken in hand, and was completed by January 1st, by which time the new hydraulic lifts in the staircases were in working order, so that the great removal of stores into their different new places could be undertaken.

On January 4th the stage floor was opened and gutted. The new stage floor was closed in on April 4th, when the whole of the work was practically completed, with the exception of some minor mechanical details which were completed by the end of April. The gutting of this lower portion of the stage alone comprised a wreckage of nearly 1,000 cartloads of timber and the erection of 150 tons of complicated steel work.

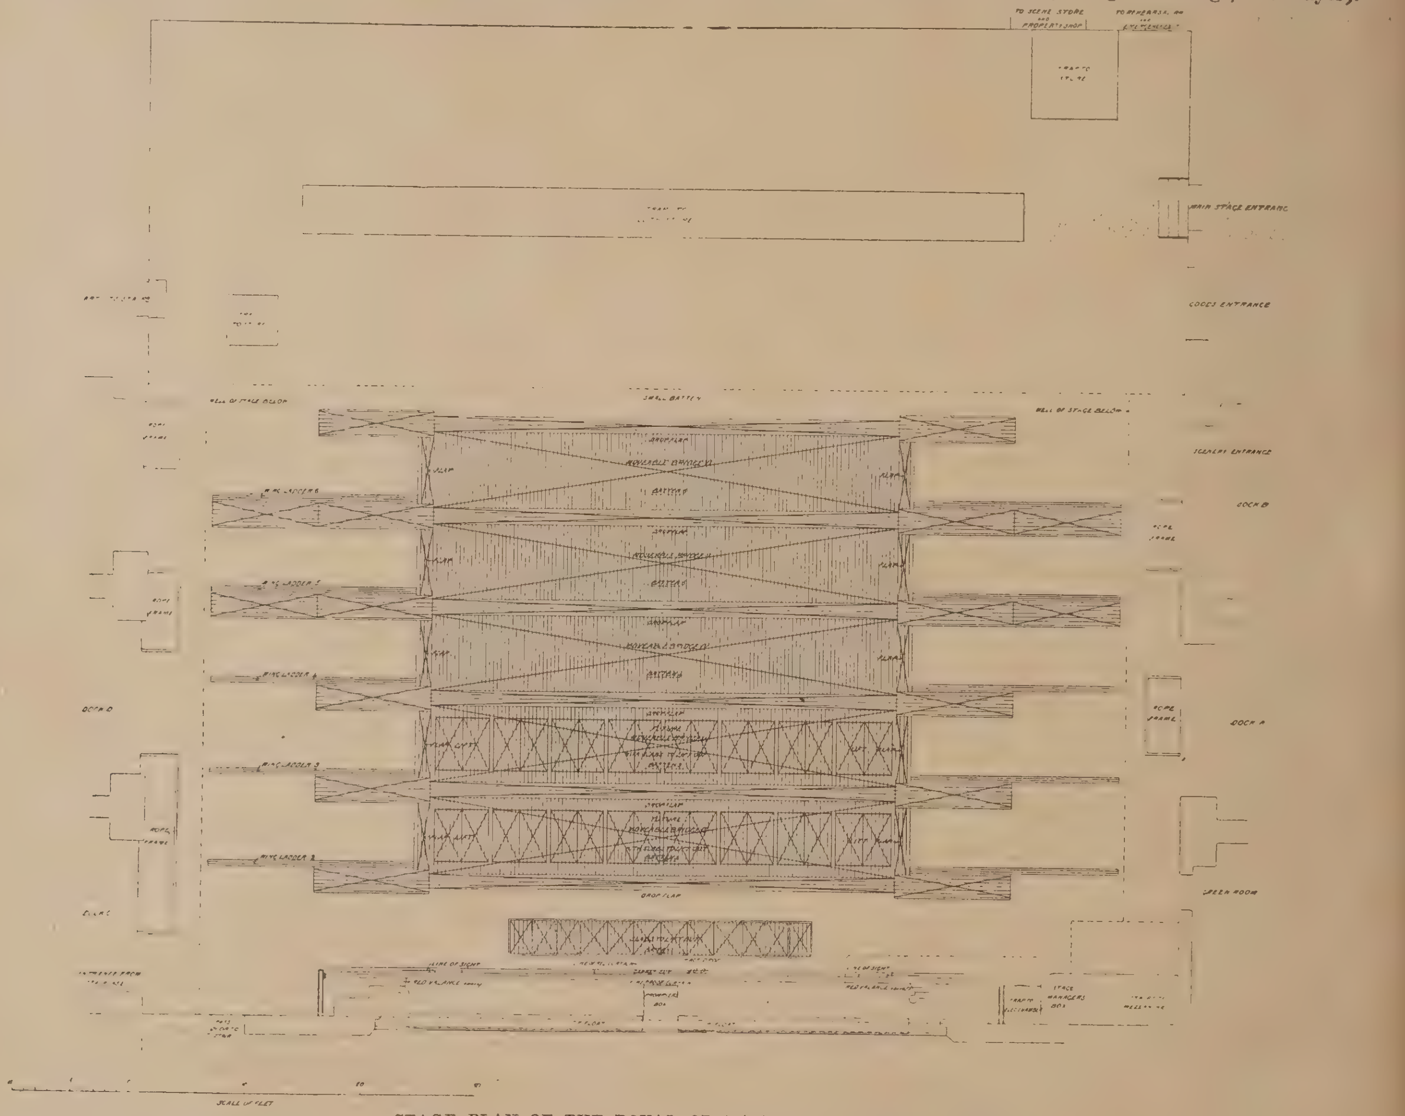
It will thus be seen that the two principal problems, *i.e.*, that of raising the roof and that of gutting the stage, occupied respectively two and three months, both pieces of work having beaten English records for operations of their respective classes, and having run American records very closely. The circumstances were, of course, very peculiar, owing to lack of space and the enormous quantity of storage that had to be handled, and much of the work was of an exceptionally dangerous character and of considerable risk to the workmen employed.

Nevertheless, not a single accident, much less a fatal casualty, occurred; and this is again a record, and compares particularly favourably with the accident list of the Berlin Court Theatre, which, during certain similar alterations, comprised one killed and seventeen seriously injured. The results, both in time and in lack of accident, must be attributed to a great extent to the co-operation of all parties concerned, not forgetting the artisans and labourers, who were, to a great extent, new to the class of work required.

The entire arrangements on behalf of the Grand Opera Syndicate were in the hands of the directors, Earl de Grey and Mr. H. V. Higgins, who, after consultation with their business manager, Mr. Neil Forsyth, and their stage manager, Mr. Neilson, based their programme almost entirely on a scheme prepared at their direction by their technical adviser, Mr. Edwin O. Sachs, in 1899, shortly after the Opera House had been taken over. The final designs were entrusted to Mr. Sachs's execution, who was assisted by his chief assistant, Mr. Lister, Mr. Thomas Kissack acting as clerk of the works.

The general contractors were Messrs. Colls & Son (manager in charge, Mr. Collins; foreman, Mr. Dowse). The ironwork contractors for everything above the stage level were Messrs. Lindsay, Neal & Co., Ltd., whilst the entire complicated structural and mechanical ironwork below stage level, including the stage "bridges" and lifts, was by Messrs. Drew-Bear, Perks & Co. (manager in charge, Mr. Simco). The electrical power plant for the "under machinery" was provided by the Thames Ironwork Shipbuilding Co., Ltd., of Blackwall (manager in charge, Mr. Flood); whilst the whole of the elaborate counterweight mechanism above stage level was provided by the well-known Berlin stage mechanist and contractor, Mr. F. Brandt, who personally attended to the installation of his appliances in London. The fire-resisting curtain was by Messrs. Merryweather & Sons, Ltd., and the alterations in the auditorium by the Army and Navy Auxiliary Supply, Ltd. (manager in charge, Mr. Player).

Mr. Sachs is particularly anxious to acknowledge the splendid assistance rendered him by the contractors and their representatives, and to particularly note the cordial manner in which the various firms worked hand in hand under very trying conditions. He also wishes to express his best thanks to Mr. Robert Affleck, stage mechanist, lately of the Court Theatre, who, by advice on matters of detail, and by his ready assistance in facilitating the building operations, rendered most valuable services. The whole of the stage will henceforth be under the control of Mr. Affleck, ably assisted by the theatre electrician (Mr. Crawshaw), who during the building operations, had charge of the alterations to the electric lighting equipment. The new Opera season commenced on Monday in last week.



STAGE PLAN OF THE ROYAL OPERA HOUSE, COVENT GARDEN.

Some Particulars of Mr. Sachs's Career.

Mr. Sachs recently formed the subject of one of "Celebrities at Home" published in the "World." The writer says: On reaching Dover with Mr. Sachs, who has entertained you *en route* with his adventures in Russia, his sketching tours in East Prussia, his health trips to Egypt, and his experiences as a fireman in Berlin and Vienna during the seven years of his professional studies abroad, you place yourself behind a pair of horses who seem to share their master's love of haste, and who bowl the victoria swiftly along the sea-front, and, "springing" the hill that sweeps past Dover Castle, trot smartly over the Cinque Ports Road leading to Deal. A sharp turn to the right, however, presently takes you through the village of St. Margaret's-at-Cliffe, with its historical Norman church. Then the coastguards' station on the top of the cliff is passed; and a little while afterwards you traverse a steep carriage-way which, after passing between two massive piers, brings you in sight of South Foreland House (Mr. Sachs's residence), an imposing Italian villa which, with its white-glazed brick walls, Renaissance detail and terraced front set in a frame of green might well have been transported from San Remo or Bordighera, while the view you survey from the terrace to which you have mounted is magnificent in the extreme. As regards Mr. Sachs's many literary achievements, order and system are vital features; and not the least of these you will find in a commodiously constructed bureau in his study, the carving of which was designed by one of the ladies employed by him in architectural work. "Modern Opera Houses and Theatres" is indeed a monumental achievement, giving the detail of construction, organisation and management of every dramatic house in Europe. It was published serially in folio during the years 1896, 1897 and 1899, and represents an exhaustive study of the subject and the labour of over eight years. The text was personally written in the late hours of the night, while the illustrations were prepared, under Mr. Sachs's direction, by an admirable staff. The volumes have been subscribed to by every potentate and learned society in Europe; and it has been eulogised by every organ of the press. Nor does it lessen one's interest in these volumes to learn from Mr. Sachs that it was while he was keeping watch and ward as a fireman of the Vienna Municipal Fire Brigade—a self-sought occupation—during the Musical and Theatrical Exhibition in that city, that he conceived the notion of compiling his comprehensive work on the theatre architecture of the world. (Mr. B. T. Batsford, by the way, much regrets to announce that the second issue, promised for the opening of the opera season, has been unavoidably delayed by the illness of the author. It is now scarcely probable that Mr. Sachs's work can be re-issued before the autumn.)

Then you may turn to his "Stage Construction," embellished with reproductions of some of Herkomer's charming studies in lighting; or you may marvel at Mr. Sachs's statistical record work on conflagrations from 1797–1897, giving the details of eleven hundred fires in theatres all over the world; while you will scarcely need be told that fire and its prevention is Mr. Sachs's speciality, after you have dipped into the volumes containing the reports of the experiments made in pursuit of non-inflammable architectural and building material by the British Fire Prevention Committee, of which Mr. Sachs is the chairman as well as the founder, directly after the Cripplegate disaster in 1897.

The incidents of Mr. Sachs's career after he had completed his studies at the London University College School, and sought to make himself proficient in foreign languages on the Continent, are by no means destitute of romantic interest. The future of the young student was assuredly foreshadowed when he nominally apprenticed himself at Falkenburg, and learnt to lay bricks during the erection of a new wing to this finishing school. The practical bent of his character and its mechanical tendency loomed larger as he set himself to learn "smithy" work on commencing his architectural studies under Ludwig Hoffmann, the designer of the Imperial Law Courts at Leipsic, and now city architect in Berlin. Subsequently Mr. Sachs entered the office of the celebrated Professor Ende, president of the Prussian Royal Academy; and during this period he first devoted himself to the questions of theatre construction, protection from fire in theatres and the minimising of the liabilities of panic in them. After Mr. Sachs had studied his profession from every standpoint, and had travelled with an observant eye, supplemented by the services of a well-filled sketch-book carried through all the northern capitals of Europe, he returned after seven years to London, where, it is needless to say, he has acquired an extensive practice as an architect, and where he is recognised in technical circles as a leading authority on matters relating to fire protection, theatre building and stage machinery.

Engineering Notes.

The Mond Gas Bill, referred to in our issue for May 8th, p. 267, has been approved by the Select Committee of the House of Commons.

Mr. Morgan Williams, M.Inst.C.E., of 39, Victoria Street, Westminster, has been appointed consulting engineer to the new Willesden Infirmary by the Willesden Board of Guardians.

The Fever Hospital, Birmingham, has just been supplied by Messrs. E. H. Shorland & Brother, of Manchester, with their patent double-fronted Manchester stoves with descending smoke flues.

Electric Light in Christ Church, Oxford.—The Governing Body of Christ Church have decided to carry out the electric lighting scheme of their consulting engineer, Mr. Morgan Williams, M.I.C.E., of 39, Victoria Street, Westminster, The contract has been placed with Messrs. Hill. Upton & Co., of Oxford.

A New Bow Bridge.—The West Ham Corporation and the London County Council are formulating a joint scheme to widen old Bow Bridge, the main outlet of London on the eastern side, at a cost of £19,000. The old stone bridge is only 40ft. wide, and in its place it is purposed erecting an iron girder bridge 70ft. wide.

The Electric Lighting Effects in the "Cinderella" pantomime at the London Hippodrome, which were carried out so successfully on the "Electric Lighting Boards" system, are now being repeated for various purposes in different parts of the country. The entire Irish section of the Glasgow Exhibition has been decorated by a scheme of garlands interspersed with shamrocks provided by the Electric Lighting Boards Company, of 7, Pall Mall, S.W. A similar scheme of decorative illumination has been installed for the Café Chantant at the Crystal Palace, whilst the effects have also been used for decorative purposes on several occasions at the Grafton Galleries.

A Novel Engineering Feat was accomplished on the Tyne recently, when the spans and roadway of the bridge connecting Newcastle and Gateshead, which had been built 4½ft. to the eastward of the position they were ultimately to occupy, were moved over into place. The building of the bridge has been remarkable as an example of modern engineering practice. An old bridge existed, and the new bridge has been built on precisely the same site the old one occupied. The traffic has yet gone on uninterruptedly. The new piers were built round about the old one, and the roadway and spans were erected a little above and 4½ft. to one side of the old roadway and spans, a temporary footway meanwhile being provided for foot passengers. The old piers were then taken away and the new roadway was lowered to its proper level, and moved over into its permanent position by means of hydraulic jacks in one morning. The total weight of the bridge was 1,600 tons, and the jacks were capable of exerting a pressure of 1,500lb. to the square inch. The bridge is built of steel and is of the American type, but the details are strictly in accordance with the best English practice. There are four spans, two of 252ft., and each of the others 170ft. The total length of the bridge and its approaches is 1,500ft. Its total weight is 2,900 tons. The bridge is carried on cylinder foundations, each 8ft. in diameter and sunk to a depth of 50ft. below low water. There are four cylinders to each pier. The engineers of the bridge are Messrs. Sandeman and Moncrieffe, of Newcastle, and the builders are Sir William Arroll & Co., of Glasgow.

Water from the Lake District.—The Earl of Jersey's Committee of the House of Lords has passed the preamble of a Bill promoted by the corporation of Barrow-in-Furness to empower them to impound the upper waters of the River Duddon and the Seathwaite Tarn in the Lake District, and to obtain from 2,000,000 to 3,000,000 gallons of water per day from these sources according to the quantity of water in the river, that is to say, so long as the flow does not fall below a certain amount. The measure was opposed by the urban district council of Millom, the Hod Barrow Mining Co., and the Millom and Askam Hematite Co., who all objected because they feared that the effect of diminishing the flow of the Duddon would be to cause the closing of the channels in the river estuary and so to put a stop to the sea trade of Millom.

LIVERPOOL ARCHITECTURAL SOCIETY.

PROFESSOR F. M. SIMPSON (president) took the chair at the annual meeting of the Liverpool Architectural Society, held last week. The report, which was adopted, stated that the membership of the society now stood at 146 members—namely, 55 fellows, 53 associates, 20 students, and 18 honorary members, an increase of 12. The library was being more highly appreciated. The accounts showed an increased credit balance. On the election of officers. the executive was unanimously chosen, while the council was, by rule, the subject of a ballot, the result being: President, Professor F. M. Simpson; vice-presidents, P. C. Thicknesse and T. E. Eccles, A.R.I.B.A.; honorary secretaries, Hastwell Grayson, B.A., A.R.I.B.A., and G. W. Fraser, A.R.I.B.A.; honorary treasurer, James Dodd; honorary librarian, E. G. Dickinson; council—fellows: C. E. Deacon, F.R.I.B.A., T. E. Eccles, A.R.I.B.A., H. Hartley, F.R.I.B.A., E. A. Ould, F.R.I.B.A., James Strong, P.C. Thicknesse, W. E. Willink, M.A., F.R.I.B.A.; and associates: E. P. Hinde, A.R.I.B.A., and Arnold Thornely, A.R.I.B.A. In closing the session, the president expressed thanks for his re-election, and referred to the pleasure he found in a visit to the East, where he collected a number of architectural photographs, which he had placed on exhibition. He thought it might be advisable at the opening of the new session to exhibit drawings or photographs of any interesting buildings, new or old, noted by members during their holidays. He hoped more papers would be contributed by members, the tendency of the society having lately been to rely too much on outside aid. He rejoiced in the spread of architectural education, in which Liverpool had led the way, and he said there were no doubt that as the new universities increased in number, architecture and similar subjects would be admitted to the regular degree course. Dealing with Liverpool's recent architecture, he alluded with pleasure to the breadth of scale and simplicity of treatment shown in the White Star offices, Parr's Bank, and the Royal Insurance offices, and said Liverpool had three open spaces at its disposal. The ground at the west of St. George's Hall was, he believed, to be architecturally treated. The space formerly occupied by St. George's Church awaited its fate. The most important space was that of the late George's Dock, which might be converted into one of the finest squares in Europe, containing some of the finest buildings, and form an impressive entrance to the city from the Mersey. He hoped Liverpool would avail itself of this great opportunity.

Brighton Improvements.—By a Bill just passed the Brighton Corporation are empowered to buy the Brighton Aquarium for £30,000. They are to spend £60,000 on improvements.

A New Church at Norbury is being erected. The new church, when built, will be called St. Philip's, and will be a chapel-of-ease to Christ Church. The site of the new church is on the Norbury Court Estate, at the top of Beatrice Avenue, which is the next turning past Pollard's Hill North, on the same side. The whole of the church is not to be built until funds allow, and the present portion is estimated to cost £4,450. A further sum of £2,500 or £3,000 will be required to complete the building.

Bricks and Mortar.

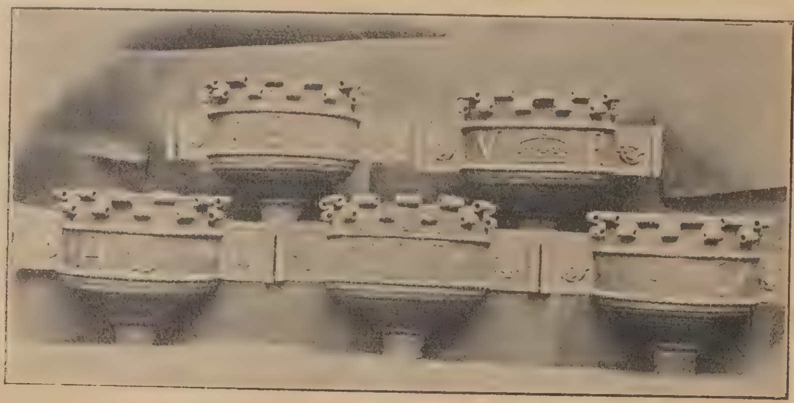
APHORISM FOR THE WEEK.

Wherever there is a beautiful statue there is a place of pilgrimage.—RICHARD JEFFRIES.

Our Plates. THE general view of the Glasgow Exhibition is in illustration of our article on p. 292 of this issue. We are enabled to reproduce it through the courtesy of the "People's Journal," Dundee.—Particulars of the new lifts at the Royal Opera House, Covent Garden, will be foundi in this issue, p. 303.

Rodin's Porte de l'Enfer. SOME years ago M. Rodin was commissioned to design and execute a doorway to be called the "Porte de l'Enfer," which was to serve as the entrance to the Musée des Arts Decoratifs. The Musée, however, is going to be removed to the Pavillon de Marsan, and Rodin was asked to go there and select the most suitable place for the *porte*, but the official architects did not agree with the project. and the question now is—what is to become of the doorway? Interviewed on the subject, the artist said that to him it was a matter of indifference where the *porte* may be placed. He had wished to give a new interpretation to bas-reliefs, to conceive a work where the decoration would harmonise with the *ensemble*, and so arranged that the play of light would give artistic diversity to the various motives of the sculpture. He hoped he had been successful: that alone interested him.

Stretton Church. In our issue for April 3rd last, on p. 147, we gave some particulars and an interior view of Stretton Church.



RAINWATER PIPE-HEADS IN LEAD, STRETTON CHURCH, STAFFORDSHIRE.
J. T. MICKLETHWAITE & SOMERS CLARKE, ARCHITECTS.

The rainwater pipe-heads illustrated on this page were all executed in lead from designs by Mr. J. T. Micklethwaite, of Messrs. J. T. Micklethwaite & Somers Clarke, Dean's Yard, Westminster, from whose designs the church was erected.

Archæological Research in Greece. THE researches carried out by Professor Fürtwangler, the eminent archæologist, in the precincts of the Temple of Athena, in the island of Ægina, have resulted in the discovery of five marble heads belonging to the famous series of Æginetan sculptures in the Glyptothek at Munich. The sculptures which adorned the pediments of the temple were discovered in 1811, and shortly afterwards brought to Munich by King Ludwig I. of Bavaria; the missing portions of the statues were supplied by Thorwaldsen. Three of the heads now discovered are those of helmeted warriors, the other two belong to female figures. As the export of antiquities from Greece is forbidden, the heads cannot be replaced on the statues to which they belong, but it will be possible to substitute casts for the heads designed by Thorwaldsen. A finely-executed hand belonging to a female statue, and other fragments, have been brought to light. The search for submerged statues near the coast of Anticythera has been resumed since Easter, but only some pedestals and a horse's head in fair preservation have been brought to the surface. Some fragments of an ancient ship and its anchor have been recovered.

Dr. Johnson's House. THE house in which Dr. Johnson was born at Lichfield has become the property of the Corporation. The town council have arranged to open the house at Whitsuntide, when the public will be admitted in much the same way as at other birthplaces—at Stratford-on-Avon, Olney and elsewhere. This famous house has undergone various vicissitudes since it was in the possession of Dr. Johnson, having been among other things a restaurant. Writing about twenty-five years ago, Mr. John Hewitt, the archæologist, described the house as "a goodly mansion at the north-west corner of the market-place." It was the residence and shop of Michael Johnson, the father of the doctor, and was in 1874 still "essentially the same structure." Michael Johnson was, says Mr. Hewitt, a bookseller, but was somewhat comprehensive in his dealings. He dispensed not only choice editions of Homer and Virgil, but "Last Dying Speeches" and quack medicines. Two doors away is the Three Crowns Inn, where Dr. Johnson put up when visiting Lichfield. He was there with Boswell in March, 1776, and the incidents of the visit are duly recorded in the great biography. In 1784 Johnson was in Lichfield for the last time. "While there," says Bothwell, "he felt the revival of all the tenderness of filial affection. The following circumstance, mutually to the honour of Johnson and the corporation of his native city, has been communicated to me by the Rev. Dr. Vyse from the town clerk: Mr. Simpson has now before him a record of the respect and veneration which the Corporation of Lichfield, in the year 1767, had for the merits and learning of Dr. Johnson. His father built the corner house in the market-place, the two fronts of which, towards Market and Broad Market Street, stood upon waste land of the corporation, under a forty years' lease, which was then expired. On the 5th of August, 1767, at a common-hall of the bailiffs and citizens, it was ordered (and that without any solicitation) that a lease should be granted to Samuel Johnson, Doctor of Laws, of the encroachments at his house, for the term of ninety-nine years, at the old rent, which was five shillings, of which, as town clerk, Mr. Simpson had the honour and pleasure of informing him, and that he was desired to accept it without paying any fine on the occasion, which lease was afterwards granted, and the Doctor died possessed of this property." Mr. J. W. Croker, commenting on these statements, expresses doubt as to Johnson's father having built the house, and affirms that the lease was only of the encroachment made by a shop window jutting out into the street.

Wraxall Church. THE members of the Axbridge branch of the Somerset Archæological and Natural History Society recently paid a visit to Wraxall and Tickenham. The first object of interest, after passing Clevedon Court and the new Clevedon water-supply, was Wraxall Church, which is dedicated to All Saints. Here some little time was spent in viewing the interior and exterior, and Mr. Ernest E. Baker, hon. secretary, read a paper. He said that the church had been recently restored. Mr. Ferrary, in 1881, said that the church was one of the finest in that part of Somerset, and was evidently originally a Norman foundation, although there was not much left which belonged to that date, the south doorway to the porch being the only Norman work remaining. There were traces of an Early English church, which must have been built afterwards, and the porch and parvise are of that period. The tower was a specimen of the middle of the Perpendicular period, of a very plain and massive type, the beautiful pinnacles built upon the buttresses being worthy of attention. There was a very fine tower arch, with remarkably good mouldings. There was a sanctus bell turret, which was not very usual in England. The feature of the greatest interest was perhaps the steps in the eastern wall of the porch, with respect to which different writers had different ideas. Its use was doubtless to accommodate the choir at different functions. On the north side of the chancel was the tomb of Sir Edmund and Lady Ann Gorges, dated 1512. The Gorges were lords of the manor of Wraxall for centuries. In the churchyard was a fine cross, well and carefully restored. The company next visited the Manor House, Tickenham. The church was found to be a building of much interest, comprising features of all styles of architecture, from the eleventh to the sixteenth centuries. Various other features of interest were described and inspected.

Exeter Architectural Society. AT the annual meeting of Exeter Diocesan Architectural and Archæological Society, held at Kenton, it was stated that there had been no public building of importance finished in Exeter or Devon that the committee were aware of during the past twelve months. The aim of the society was to prevent old buildings being altered and over restored. The church at Exbourne had had its nave restored, and the next portion of the work to be taken in hand was the nave seating. The old screen had been restored. Black Torrington Church restoration would soon be commenced. Sampford Courtenay Church had been reopened after a most successful restoration, and Inwardleigh Church had also been restored. There is a balance in hand of £32 6s. 11d. Officers were elected as follows: Patron, Bishop of Exeter; president, Hon. Mark Rolle; vice-presidents, Dean of Exeter, Chancellor Edmonds, Bishop of Crediton and Mr. J. Brooking Rowe; hon. secretaries, Rev. R. Medley Fulford and Mr. J. Jerman; hon. treasurer, Mr. J. T. Browne-Mason; curator, Mr. C. J. Tait; committee, Revs. W. P. S. Bingham, F. B. Dickinson, Roger Granville, W. Hope, O. J. Reichel and E. V. Freeman, Dr. Brushfield, Messrs. E. H. Harbottle, J. Newnham, Harbottle Reed, T. Kennet-Ware and A. J. Mackey. Mr. J. Newnham, A.R.I.B.A., read a paper on "Vestries," and notes were contributed on the excursions which took place last year by Rev. R. Medley Fulford. An inspection was afterwards made of the parish church, where the vicar read notes chiefly concerning the screen.

Winchester Lady Chapel. The Lady Chapel of Winchester Cathedral has lately undergone restoration. When Benjamin West's picture was removed from the great screen information was received that his countrymen desired to obtain it for their native land, and after a somewhat lengthened negotiation it was sold last summer to Mr. J. Pierpont Morgan for the sum of £1,500, and is now in New York. The chapter at once decided that this money should be expended upon the restoration of the Lady Chapel. The north window of the sanctuary, the only one not filled with stained glass, became the first charge on the funds, and the designs which Mr. Kempe had already prepared were carried out. The pavement of the entire chapel has been renewed, while the sanctuary floor has been laid with polished Ashburton and Dove marble. The delicate sixteenth-century woodwork of the stalls has been carefully cleaned and repaired, and the walls have been hung with drapery, that over the frescoes being, however, fixed to a hinged framework, so that any portion of the paintings can be easily examined. The fine kneeling figure of Bishop North, by Chantry, which had been inconveniently placed on the east wall, has been removed and refixed in the retro-choir, east of Bishop Waynflete's Chantry. The reredos will also be removed when funds are forthcoming for the carved and coloured oak triptych which it is desired to place there.

R. I. B. A.

PROFESSOR FLINDERS PETRIE ON EGYPTIAN ARCHITECTURE.

A MEETING of the Royal Institute of British Architects was held on Monday evening last, the chair being occupied by Mr. William Emerson (the president). Mr. Emerson referred with great regret to the death of Mr. Arthur Cates. Mr. John Slater, Mr. William Woodward and Mr. T. M. Rickman also spoke a few words respecting their deceased colleague, and it was decided that a vote of condolence should be sent to Mrs. Cates in her bereavement. Mr. Alexander Graham announced the decease of Mr. Ebenezer Gregg, who was elected a Fellow in 1870, and was one of the Board of Examiners. The Institute had sent a wreath to his funeral, and it was agreed that a letter of condolence should now be addressed to his relatives. Sir Lawrence Alma-Tadema was then received as an Hon. Fellow, after which Professor W. M. Flinders Petrie read his paper on "The Sources and Growth of Architecture in Egypt." He said that in no respect was our view of the origins of the arts more enlarged than in the architecture of Egypt. Ten years ago we were starting with the most highly-finished work of the Fourth Dynasty, the great pyramid of Khufu, and were groping in the dark for any clues to the growth of such surpassing construction. To-day it can be shown how every feature arose, and the adoption of stone for building can be dated to a single generation. The unwrought materials, which were everywhere to hand in Egypt, were palm-ribs, papyrus, reeds, maize-stalks and mud, together with palm-fibre roughly twisted. A striking sight of the

Beginnings of the Building Art

may be seen any day in a nomad settlement on the desert edge. Side by side stand (1) a black goat-hair Arab tent, long and low, open always on the leeward side; (2) a tent fenced along part of the open side with a row of maize stalks; (3) a tent fenced all round with maize; (4) a tent in a maize fence mud-plastered; (5) a dwarf wall of brick round the fence; (6) a high brick enclosure with a tent inside to roof it, the tent ropes stretching out through the wall; lastly, a roof is put on the wall, and the tent has disappeared.

The early Egyptians seem, however, to have usually roofed their reed huts with domed roofs, to judge from the engraving of a hut on ivory, at the rise of the First Dynasty (4800 B.C.). The next feature is the strengthening of the corners of the hut by placing at each angle a bundle of reeds lashed together, as seen in the hut on the mace of Narmer. Here we have the origin of the torus-roll down the edges of the buildings, used till the latest stage of the architecture. The lashing together was always retained as an ornament, although the meaning of the roll was long lost.

When papyrus stems were used for walling, instead of reeds or maize-stalks, the top was rather weak if stripped of its leaves; hence they were retained and bound together, and the feathery tops served as a barrier above the wall, and finally as an ornament.

Palm Ribs.

Besides these materials, palm-ribs may be seen still used for fences. They are set upright with all the leaves on them, at a few inches apart, and strengthened by other ribs interwoven diagonally each way; just below the weak part of the tip a line of ribs is lashed on with palm-fibre, and the loose nodding tips serve as an effectual barrier to men and animals. The whole is finally plastered with mud up to the top lashing, and forms a very strong fence, which will last for many years. Such a fence or wall is figured as the front of an early shrine hieroglyph in the Fourth Dynasty.

Translated into stone, this became the constant feature of every Egyptian building, and this cornice retained to late times the palm-leaf ribbing which proclaimed its origin.

We have preserved to us some views of simple shrines made of the natural materials, similar to the huts of maize-stalks still used by the peasant. Here we note the roof sloping backward, and carried on far before the open front, so as to cast a shade, while it is supported on two front pillars of stalks. This was the original type of the rustic shrine adopted as a hieroglyph, and preserved to us from the Fourth Dynasty.

Mud-Brick.

The next material to be noticed is mud-brick, one stage beyond the rough mud plastering. Brick houses and town walls remain from the prehistoric age, probably about 6000 B.C.; and a model of a town wall, with watchmen looking over it, belongs to a rather earlier time.

Regular brickwork developed in use in the prehistoric time, and some arched brick tombs are probably of this age. There can, however, be no doubt of the barrel-vaulted passage in the tomb of King Neter Khet (found this year) belonging to the beginning of the Third Dynasty (about 4200 B.C.), and the magnificent brickwork and arching of the Fourth Dynasty (about 3400 B.C.) shows a long familiarity and free use of it.

Coming to wrought materials, wood was the earliest in use for construction. The prehistoric graves were often lined with matting, and this was, in the later prehistoric, sometimes supplanted by a wooden lining. In the royal tombs at Abydos (4700-4500 B.C.) all of the wooden sides have been destroyed; but the evidences remain most clearly on the cross walls that were built to form cells around the wooden chamber for the offerings. These walls are plastered and whitewashed on the sides, but the ends are all rough brick, evidently built against a pre-existing timber wall, as the mud mortar has taken the cast of the grain of the wood wherever it touched it. The floors were usually of wood: one of the most complete shows the boards about 2in. thick, resting on beams at the sides and down the axis of the chamber. The roofing was also of wood, as in some cases the casts of the rough-hewn ends of the roofing beams remain in the brick walls of the chamber.

Construction of Early Tombs.

The author referred to the tombs of King Qa (4650 B.C.) and King Zet (4600 B.C.), and gave details of their construction. This form of construction is the forerunner of the greatest architecture of the pyramids. For the wooden chamber we find a stone chamber substituted, and the beams of the roof are of limestone or granite in place of wood. But the continuity of the general form and system is unbroken. The earliest royal tombs are plain pits roofed in, as in the pre-historic time. By 4650 B.C. a wooden lining forms a complete chamber, with brick cells around it, but no entrance. Under Den-Setni, 4600 B.C., an entrance stairway is added on the east side. Under Qa, 4500 B.C., the stairway is turned to the north. And the steps from this to the usual pyramid form a north entrance passage sloping down to a chamber is merely a change of material, but not of form or position. The external form of the mastaba tomb, from which the pyramid was developed (or rather *on* which the pyramid was superveloped) is exactly that of the rectangular mass of sand above the tomb, held in by the retaining wall of mud-brick, with a large external batter, as over the tomb of King Zet.

The author, having referred to the favourite lattice-work, the analogue of the mushrabiyéh work of Cairo, went on to trace

The Course of Stone-Working.

The first actual building of stone is the pit-chamber of King Khasekhemui, in the middle of the Eleventh Dynasty, about 4350 B.C. The limestone courses are tolerably regular, varying one or two inches either way. The faces of the blocks follow natural cleavages as far as possible; but most of the faces are hammer-dressed, and then adzed over to level them. The joints have plaster in them, and also spread over the open joints on the face. The same king also worked in grey granite, as two large building blocks with inscriptions of his have been found at Heirakonpolis and at El Kab. But building in limestone was still rare, and it is probably to the latter half of the Second Dynasty, about 4350–4200 B.C., that must be assigned a series of rough stone pyramids, which stand at El Amrah, Nubt and El Qula. These are all built of unhewn blocks found loose on the desert and cliffs. Each has successive faces of external finish, which have been coated over with added masonry.

The author next described the fine tomb of King Neter-Ket, probably second king of the Third Dynasty, about 4200 B.C.; the great stone pyramid of Saggara, probably of the same date; and the tomb of King Seneferu at Medum (4000 B.C.).

The Derivation of the Pyramid Structure.

It is important to see clearly how the pyramid structure is derived from the wooden tombs in unbroken succession, as it has by some been derived from the dolmen and chambered burrow. These structures are quite unknown in Egypt; whereas the continuous stages between the prehistoric pit-grave and the greatest and most accurate structure ever built are clearly traceable. Even the preparation for a pyramid remained just the same as for the wooden tombs of the First Dynasty.

The author concluded with some notes on the subject of pillars.

The wooden column appears as an octagon in the models found in the First Dynasty, and in the actual pieces he had discovered in the Twelfth Dynasty, and the copies of such in stone at Beni Hasan. The fluted wooden column is found copied in ivory in the First Dynasty tombs, and is well figured as a hieroglyph in the Fourth Dynasty.

The most peculiar form of column is that derived from the tent-pole. This was the origin of the strange form known as the inverted bell capital in the Eighteenth Dynasty at Karnak.

Lotus Columns.

The earliest example known of the lotus column is of the Fifth Dynasty (about 3600 B.C.). The later examples of the Twelfth Dynasty, of the Eighteenth Dynasty, and of the Nineteenth and Twentieth Dynasties show only a series of lamentable decadence. Each age in Egypt had its special excellence. In the Eighteenth Dynasty a delicate and freely flowing ornamental treatment; in the Fifth Dynasty the finest figure sculpture; in the Fourth Dynasty the grandest constructions; and in the First Dynasty the most lavish use of hard stones for hand objects and table furniture. Diorite, porphyry, and such materials were cut in thin and beautiful forms with a familiarity which was never known in later times. But every branch of art, when once it had fully grown, decayed rapidly, and the later work in every respect cannot bear comparison with the older triumphs.

The Discussion.

A discussion followed. Professor Aitchison moved a vote of thanks to Professor Petrie for his excellent paper. This was seconded by Sir Lawrence Alma-Tadema. Sir Martin Conway remarked that the development of Egyptian architecture was in direct contrast to the teaching of Ruskin, that forms particular to one material should not be copied in another. Greece had done the same as Egypt, and we might take the lesson to heart at the present time, when metal construction was superseding that of wood and stone. Dr. Murray, Mr. Phenè Spiers and Mr. Hugh Stannas also spoke.

In replying to questions, Professor Petrie said that the Egyptian construction was strictly indigenous, but he could not say the same of the art—that came from at least two different sources. Referring to the wood used, he said that the large beams had a straight grain and were probably of cedar brought from Syria, while the flooring boards were probably of acacia. As to the peculiar construction of town walls with horizontal courses between curved portions, he did not think that the earthquake theory accounted for them: we would need look in other directions for an explanation.

A Nameless Church.—According to a contemporary, a little church at Loudwater, in Buckinghamshire, which was erected in the year 1788, is nameless. The village was formed into a separate parish in 1866, but churchwardens have never been appointed either by the vicar or the parishioners; therefore no vestries are ever held. The church, which is in the diocese of Oxford, has never been dedicated to a patron saint.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Sanitary Inspectorship Examination.

Newcastle.—Coaly Tyne writes: "What books should be studied for the above examination? What is the full address of the Sanitary Institute?"

"Municipal and Sanitary Engineers' Handbook," by H. Percy Boulnois (Spon, 15s.); Reid's "Practical Sanitation" (Griffin & Co., 6s.); Coleman's "Sanitary House Drainage" (Spon, 6s.); Moore's "Sanitary Engineering" (Batsford, 30s. nett.), and Knight's "Annoted Model By-laws." We should advise you if possible to attend the courses of lectures held by the Sanitary Institute. Particulars can be obtained from the secretary of the Institute, Parkes Museum, Margaret Street, W.

Polish for Outside Signs.

Walsall.—Nemo writes: "Which is the best method of polishing signs, shop-fronts, &c., so that the weather will not affect the polishing?"

Good French polish is satisfactory, and can be relied upon for this kind of work. It is, of course, expensive, but good work must be paid for. The best carriage varnish is also suitable, and after careful application with a fine brush should be polished in with a piece of cloth.

Calculating Weight of Timber Beams.

Newcastle.—Formula writes: "Kindly answer the following question, taken from the R.I.B.A. Kalendar for 1901: 'The formula for calculating the weight which a timber beam will carry is $w = \frac{cbd^2}{l}$. What do you understand by this; and why does the strength of a beam vary as the breadth, while it varies as the square of the depth?' What do the letters in the formulæ stand for; and in what book can I find similar questions worked out?"

See Rivington's "Notes on Building Construction," Part IV., and Hurst's "Handbook of Formulæ." In the formula, w = breaking weight in cwts. in the centre; c = a constant found by experiment, varying for various materials; b = breadth in inches; d = depth in inches, and l = span in feet.

The Refusal of Plans by Local Authorities.

Nil Desperandum writes: "I am the owner of a piece of land upon which it is my intention to build a house, but the adjoining owners are doing all they can to prevent me. One of the interested owners is the chairman of both councils whose approval I require, and plans have been disapproved in both cases owing to the drainage. (1) Is there any way that I can proceed against the councils' decision? (2) Can I require the council to provide a means of drainage at my expense? (3) Can the adjoining district refuse to allow my drain to run under a turnpike road if I maintain same for twelve months from date of completion?"

(1) You can communicate with the Local Government Board and lay the details of your case before them. It is improbable, however, that any material advantage will result, as the local authorities appear to be acting strictly within their powers. (2) According to the particulars given, it is considered that there is no legal obligation on the part of the council to provide a means of drainage to your property. (3) Under the circumstances, the local authorities may decline to allow you to construct a drain as suggested. It is decidedly unfortunate that the public sewer near your property belongs to the adjoining district, but you cannot compel the sanitary authority of that district to receive your sewage into their sewers, seeing that your property is not liable for any rates levied by them. In some instances permission has been granted to an adjoining district or property owner to connect with the sewerage system of another district for an agreed consideration, but such an arrangement is entirely a matter of mutual convenience. Many local authorities also frequently sanction the construction of a cesspool considerably nearer to a proposed building than actually required by their by-laws, if the exigencies of the site necessitate it. Probably a courteous application to your own local sanitary authority would meet with similar consideration. T. E. C.

Standard Size for Eye-Bar.

V. W. writes: "Referring to the reply in regard to the standard size of eye-bars on page 244 of your issue for May 1st, would Professor Adams kindly explain further the three diagrams of Fig. 5? Is the middle diagram—the side view of the eye—intended for insertion between the double eye of the bottom diagram? I ask this because the former is marked $\frac{3}{4}$th diameter of rod, whilst the jaw of the latter equals the diameter of the rod."

The width between jaws of double eye was not dimensioned because it may have to take two or more bars, as frequently happens in roof construction. If it had to be used in conjunction with the single eye adjoining, the width between jaws would only need to be, say, $\frac{13}{16}$in.

HENRY ADAMS.

The Temple of Ceres.

New Brompton.—Bawbee writes: "Mr. Phenè Spiers says that the Temple of Ceres at Pæstum is the only Greek example where the end triglyph comes over the centre of the column, while Hamlin's 'Architecture' says the temple is in South Italy. Did the Greeks build in Italy, or is the temple a Roman one?"

Certainly, Greek colonists built in Italy, and the remains of their temples in Sicily and Magna Graecia rank with the earliest and most imposing examples of Grecian architecture. These remains can hardly, however, be regarded as typical of the work produced in Greece itself, presenting, as they do, many features quite abnormal, and which may not be entirely due to their extremely early date, but partly to the influence of a new environment.

Any manual of ancient geography will explain how Greek colonists settled in the western peninsula of Italy, and how they gradually subdued the inhabitants, until in the sixth and fifth centuries B.C. the whole of this part of the country became one in Greek speech and manners, and received the name of Magna Graecia. Later, in 400 B.C., the Greek supremacy was checked by the inroads of the Lucani, and the name of the country was changed to that of Lucania. Lastly, in 300 B.C., the country was joined to the Roman Republic.

One of the chief coast towns of Greek origin in Lucania, was Poseidonia, which after the Roman conquest became known under the Italian name Pæstum. Of the three temples still remaining at Pæstum, that known as the great hexastyle temple of Poseidon follows most closely the Grecian Doric type. It is the best preserved, yet probably the oldest of the three; it is decidedly archaic in style, and, unlike the others, it was covered with a thin coating of stucco. The other two temples are also Doric, and have strong archaic peculiarities; at the same time they exhibit such striking departures from the normal type that their age is still, we believe, somewhat uncertain. They have generally been referred to a time not far removed from that of the temple of Poseidon; others regard them as having been subject to Etruscan influence, in which case they may still be very early; while Wilkins thought they could not be dated earlier than the time of the Roman occupation.

Respecting the so-called temple of "Ceres"—the smallest of the three—the following peculiarities may be noted as indicating a late date. The architraves over the angle columns are mitred, or jointed diagonally, a mode that does not appear to have been practised by the Greeks; the placing of the triglyphs immediately over the axes of the angle columns is peculiar to the Romans; the absence of regulæ and guttæ on the architrave under the triglyphs; the triglyphs seem to have been got out of thin slabs and inserted in the solid frieze, thus reversing the usual Greek method of making the triglyphs solid blocks, and inserting the metopes as thin slabs; the columns of the pronaos, though fluted in the Doric manner and having Doric caps, are furnished with bases.

Above the level of the frieze the stonework had entirely disappeared 100 years ago, and all the triglyphs had dropped out of their grooves, with one exception. Piranesi, however, had made a drawing when the building was more complete, and subsequent restorations have been taken from it; in Piranesi's view the corona has no resemblance to the Grecian Doric; it has no mutules, but panels are sunk into the soffit instead. In view of the fact that the caps of the columns are quite archaic in profile, the building would—if late indate—be a remarkable instance of the archaistic style in architecture.

J. A. M.

Vitruvius, Vignola and Palladio.

New Brompton.—Bawbee writes: "Who were Vitruvius, Vignola and Palladio—my text-books give no particulars?"

Vitruvius was a Roman architect and engineer who lived in the reign of Augustus. Practically all that is known of him is from his treatise "De Architectura."

Barocchio Giacomo da Vignola was born at Vignola in 1507, and died in 1573. He succeeded Michel Angelo as the architect of St. Peter's, and erected numerous buildings in Rome and other parts of Italy. He wrote a well-known work on the Five Orders of Architecture.

Palladio was born at Vicenza in 1518, and died in 1580. He was one of the chief architects of his century, and erected numerous buildings in Vicenza, Venice and other parts of Italy. He wrote the famous work, "I quattro libri dell' Architettura," first published at Venice in 1570.

Biographies of these architects are to be found in the "Encyclopædia Britannica" and biographical dictionaries.

Setting-Out Roman Ionic Columns.

Harrogate.—Ionic writes: "Is there any rule for setting out the cap of a Roman Ionic pilaster, also for the column? Can you refer me to any word illustrating them; they are not in Gwilt or Phenè Spiers' books?"

Vitruvius and Palladio give rules for proportioning and setting out caps to Ionic columns and pilasters. For setting out the volute, see p. 477 of our issue for January 23rd and p. 25 of our issue for February 13th last. It would be preferable, however, to work by the eye and hand rather than by any rules.

Expansion Joint for Iron Gutters.

Oldham.—Mac writes: "Could you give me a figured sketch of an expansion joint for cast-iron gutters in 10ft. lengths?"

Expansion joints are not suitable for cast-iron gutters owing to the difficulty of making a watertight joint without obstructing the flow. When the length is such that the expansion would be excessive, a termination should be made and a fresh length started.

HENRY ADAMS.

Canterbury Cathedral.

Bawbee writes: "At the end of Bell's 'Canterbury' are given three plans showing the extreme east end of the cathedral to have been built after 1774. I have always understood it to be Transitional. Which is right?"

It is evidently a misprint for 1174. The actual date, I believe, is 1189. G. A. T. M.

Collar Beam Roof Truss.

Querist writes: "I send a sketch (not reproduced) of a collar beam roof truss, span 28ft. 3in., principals 8ft. apart. I am unable to find the stress on the part of the principal below the collar beam. Kindly state the method graphically, and whether the usual tie rods can be done away with. Walls are 14in., piers 18in. by $4\frac{1}{2}$in., floor to wall-plate 13ft.

In order to use the graphic method of calculation assume a tie at the foot of principals and proceed as usual; the stress for the tie will be that which the walls will require to give. This form of roof is not a good one for the span you propose. With heavy timbers and buttresses it can of course be made safe, but is wasteful and weak. We would suggest the use of tension rods and a king bolt with the collar beam.

Hurst's Handbook of Formulæ and Tables.

Devonport.—M. R. writes: "I wish to obtain a 'Handbook of Formulæ, Tables and Memoranda for Architectural Surveyors,' by John Thomas Hurst. Where can I obtain it?"

Hurst's Handbook has been many times revised, and the latest edition is quite up to date. It is an excellent book of formulæ and summarised information. It is published by Messrs. E. & F. N. Spon, Ltd., of 125, Strand, W.C., price 5s., and may be obtained either from the publishers or from Mr. B. T. Batsford, of 94, High Holborn, W.C.

Position of Building Foreman.

Rufus writes: "What book would you recommend from which to learn how to take out quantities of buildings from the plans? Also, could you advise me in this: I am an apprentice to the carpentry and joinery trade, and am nearly out of my time. I served twelve months in an architect's office, and my aim is to become a clerk of works or a foreman. Do you think I could get a job with a big firm in London as a sub-foreman? I could give references."

We advise you to study Leaning's "Quantity Surveying" (E. & F. N. Spon; price 12s.). Sub-foremen are usually selected by the foremen from their men, and references count for little against personal knowledge of the applicant. The best plan would be for you to get a job as improver, or journeyman if you are sufficiently qualified, and by diligence you would be sure to secure the position in time; for experienced and trustworthy men are badly needed in the building trade. The conditions of employment are in this respect the same in the country as in London, and the latter should not be looked upon as offering any advantages over the former.

Effect of Lime on Cement.

Newbridge, Co. Kildare.—Subscriber writes: "Cement briquettes were made with water highly impregnated by lime. On testing them the necessary standard required by the department for whose approval they were tested was not reached. The standard necessary is 400lb. tensile stress per square inch sectional area. Out of four or five different cements of five briquettes of each the highest attained was only 350lb., lowest 125lb. Does the water affect the cement in any way so as to retard cohesion by reason of the lime being present, or could you suggest any cause for this failure? The cements have passed the tests on previous occasions in different places."

Lime water will weaken cement work. Lime makes the cement too "fat," and although it causes it to set quickly, it does so at the expense of strength. For this reason cements which set very quickly are generally very poor in strength. Portland cement, according to Le Chatelier, is chiefly composed of tricalcium orthosilicate, $3CaO,SiO_2$; tricalcium aluminate, $3CaO,Al_2O_3$; and tricalcium aluminoferrite, $3CaO,2(AlFe)_2O_3$, properly made cement containing no free lime. When water is added the calcium compounds are decomposed, forming, firstly, free calcium hydroxide, i.e., slaked lime; then follows the formation of crystalline hydrated calcium silicate and aluminate, the crystals of which form an interlaced mass, thus bringing about the setting of the cement. The setting takes place long before the formation of the hydrated crystals is complete, and as the action goes on the cement continually hardens. The setting and hardening of mortar, however, differ from Portland cement. Mortar made with lime first sets by loss of water; this causes the mortar to become porous, and the carbon dioxide of the air is absorbed, and the lime is slowly converted into calcium carbonate or chalk. In course of time the silica of the sand and the chalk form silicates, and these increase the hardness, but the action may take centuries to make any appreciable effect. Hydraulic limes contain alumina, and other, silicates in various proportions, and it is due to these that they have the property of setting under water. Hydraulic mortars are indeed often made by adding silicates to "fat" lime. Of course, lime alone would not set under water, as it would be dissolved or washed away, forming no crystalline structure, and this is aggravated with rainwater, which contains carbon dioxide or carbonic acid gas, as this latter increases the power of the water to dissolve chalk. It will thus be seen that free lime is deleterious to cement, tending as it does to weaken the interlacing crystalline structure which is the cause of the greater strength of cements.

Correspondence.

Examination Questions in Building Construction.

To the Editor of The Builders' Journal.

Sir,—Public attention is at present being directed to legislation upon secondary education, for which there is much need and much necessity for reform. Men and youths are urged to avail themselves of the opportunities offered for self-improvement, and, in response, from September onwards to April and May they may be seen (many of them five evenings per week) at the various polytechnics and technical institutes, foregoing alluring recreations and anxiously preparing to win certificates in the various public examinations. Such an examination, of the Board of Education—namely, Building Construction—was held on Saturday evening, May 10th, from 6 to 10, all over Great Britain. One would expect that the examiner, knowing for whom his questions were set—young architects, builders, surveyors, bricklayers, masons, carpenters, plumbers, painters, plasterers, &c.—would endeavour to word his questions as simply and as clearly as possible. But not so; his object appears to be to make the questions as ambiguous as he can, and to take the greatest amount of liberty with the syllabus of instruction definitely laid down for the guidance of the students. To give a simple comparison, students who should have been examined in Stage I. had questions from Stage III., and those in Stage II. questions from Stage IV.

Now I would ask, Is this the way to encourage young men to sacrifice their evenings and improve themselves? Surely an examination paper should be set to test a man's knowledge, not to air some eccentric foible of the examiners. I know there are thousands to whom this will appeal, and it is for this reason and to gain other opinions that I beg you will insert my letter in your valuable and well-circulated paper.—Yours truly, A STUDENT.

Standard Size of Eye-Bar.

To the Editor of The Builders' Journal.

London, E.C.

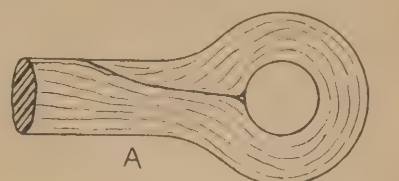
Sir,—Referring to the answer by Professor Henry Adams to "Roofs," on p. 244 of your issue for May 1st, when using Carnegie's tables it must be remembered that these are for eyes made of one particular kind of steel and for pins made of another kind of steel, both recommended as best for their particular respective purposes. The sizes given are what are kept in stock; which of those are best for the particular purpose of the constructor is for the latter to determine. He can then purchase the eye ends and weld them on to his bars or rods.

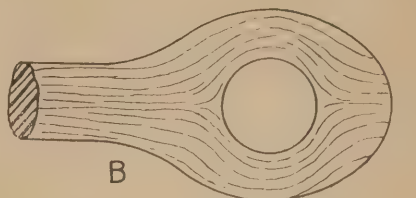
Would Mr. Adams state his formula for finding the size of pin to utilise the strength of the rod in the case of the three diagrams of Fig. 5, and state what the figures on the top diagrams mean? Are they inches and fractions of inches, giving rod diameter 1in., pin diameter $1\frac{1}{4}$in., widths at sides of eyes $\frac{5}{8}$in., width at crown 1in.; or are they to represent proportional sections in terms of the diameter of rod, the latter being taken as unity? In neither case can I come to the same results by the use of Shaler-Smith's tables, which he quotes. Perhaps I may be wrong. Would he kindly set out his calculation, when, perhaps, I may return to the subject? If it is meant that the diameter of the rod is 1in., then its sectional area is approximately ·8in., and the sectional area of the sides of eye taken together twice $\frac{5}{8}$in. by $\frac{3}{4}$in., or, say, twice ·62 by ·75 = ·93. Shaler-Smith says that their combined sections should be $1\frac{1}{2}$ times the section of the rod, which for an inch rod with eye $\frac{3}{4}$in. thick would require a width at each side of the eye of ·8 or $\frac{8}{10}$, instead of $\frac{5}{8}$ as shown. The width of the crown of the eye, given as 1, is likewise open to question; but I do not propose to enter further into the matter now, pending possible explanations and corrections.—Yours truly, A. H.

To the Editor of The Builders' Journal.

Sir,—Referring to above letter, my diagrams were not based upon any formula of my own, but simply recorded the proportions adopted by various reliable investigators. The dimensions are in terms of the diameter of rod, so that for any given diameter of rod, say, $1\frac{1}{2}$in., all measurements will be multiplied by $1\frac{1}{2}$. Fig. 4 is the only one mentioned as of the Shaler-Smith type, referring to the shape of the eye as contrasted with English practice, shown by Fig. 3. The shape of the end would also depend upon the mode of forging. For instance, Fig. 1 would be suitable for eyes made by welding, as at A, and Fig. 5 for eyes formed out of the solid, as at B, the fibres being approximately in the position shown by the lines.—Yours truly,

HENRY ADAMS.





PERTH'S NEW GASWORKS.

The New Gasworks at Friarton, Perth, were opened recently. The new works occupy an area of about four and a half acres, and are situated on sloping ground between the River Tay and Edinburgh Road. The gas-holders which supply the lighting district are midway between the new works and the city. The initial capacity of the works is equal to a make of one million cubic feet of gas per twenty-four hours, and the works are capable of being extended within the boundary walls to at least three times that quantity without change of existing plant. Entering the gates, on the right are general stores and workshops, on the left are the offices, laboratory, coal-testing room, and the sulphate of ammonia plant; in front, to the right, in one large building in two spans of roof, are the retort-house and coal-store. The coals are taken into the store by a high level railway carried on steel girders and concrete piers, the waggons are emptied into a coal-breaking machine, and, after the coal is broken to a uniform size, it is carried by elevator buckets to the overhead hoppers placed on each side of the retort house. The retort bench consists of seven double ovens placed back to back, each oven containing eight retorts 22 by 16—112 in all. The ovens are worked from two floors, the upper being used for charging and drawing the retorts, and the lower for removing the coke and ashes. The exhausters, combined with their steam engines, are in duplicate, and are each capable of passing 30,000 cubic feet of gas per hour. The contractors employed on the works were: Excavator, brickwork, &c., Mr. T. P. Jamieson, Baillieston, near Glasgow; carpenter and joiner work, Mr. William M'Quibban, Perth; slater work, Messrs. William Brand & Son, Arbroath; plumber work, Mr. James MacLeisch, Perth; plaster work, Mr. Alexander M'Ritchie, Dundee; painter and glazier work, Messrs. G. R. Douglas & Son, Perth; iron and steel roofing, railway girders and tank, Messrs. H. Balfour & Co., Ltd., Leven, Fife; retort bench, brick and ironwork, elevator, coal breaker, floor and charging machinery, Messrs. West's Gas Improvement Company, Ltd., Manchester; condensers and purifiers, Messrs. Clapham Brothers, Keighley, Yorks; exhausters and engines, Messrs. Bryan, Donkin and Clench, Ltd., London; station meter, gauges, &c., Messrs. John Milne & Son, Ltd., Edinburgh; sulphate plant, Messrs. R. & J. Dempster, Ltd., Manchester; boiler and heater, Messrs. Babcock and Wilcox, Renfrew.

Surveying and Sanitary Notes.

New Lavatories in Aberdeen.—The Aberdeen Town Council propose to construct a lavatory in the vicinity of Torry Harbour, at a cost of £400; another near Wellington Suspension Bridge, between Menzies Road and Wellington Road, at an expenditure of £425; and one lavatory in Hutcheon Street, opposite the new Dead Meat Market.

The Cleethorpes Improvement Scheme, which is estimated to cost about £25,000, and which includes the extension of the promenade and other developments along the south foreshore, is slowly progressing, and has been advanced by the action of the Sidney Sussex College, in accepting the offer by the Urban Council of £1,000 for the golf links, which cover an area of about thirty-three acres. The sea-wall is to be extended from the end of the Great Central Railway Company's promenade. The golf links are to be converted into a public park.

Mr. W. Bennett Rogers, the newly-elected president of the Auctioneers' Institute, is the founder of the well-known West End firm of Messrs. Rogers, Chapman and Thomas. Educated in France and at Brighton College, Mr. Rogers gained considerable experience in land surveying and valuing in Bedfordshire, and in 1866 commenced business in London. In the course of his career Mr. Rogers has had valuations not only in most parts of this country, but also in France, and he has had the development of not a few large estates, notably that of Westgate-on-Sea. A well-known figure at the Auction Mart, Mr. Rogers also has acted for many years and in various capacities for the royal family of France.

A City Improvement.—The Chancellor of the Diocese of London held a sitting of the Consistory Court recently for the purpose of hearing an application for a faculty under which power was sought to effect an important City improvement. The place concerned was the churchyard of the united parishes of St. Andrew-by-the-Wardrobe and St. Ann, Blackfriars. The churchyard fronts on to the Blackfriars end of Queen Victoria Street. At present the churchyard is shut off from view by means of a blank wall. This presents a rather unsightly appearance, and for some time past it has been felt desirable to make an alteration and improvement. The proposal is to lower the blank wall to about 2ft. in height, surmount this with iron railings and lay the churchyard itself out in garden terraces. There are some human remains in the churchyard, and these remains the church authorities proposed to place in a vault, which would afterwards be hermetically sealed. The cost of the work is estimated at £450. After hearing evidence, the Chancellor said he had inspected the church and churchyard, and, after having seen the plans, he was of opinion that the work when completed would be a great improvement both to the church and churchyard and to Queen Victoria Street.

A Central Highways Department.—The Roads Improvement Association, an incorporated body which has been in existence since 1886, has issued a pamphlet advocating the establishment of a Government department to deal with highways. The pamphlet says: "The increase in road traffic and the development of new means of locomotion have made the reform of the existing system of administration imperative. There are local authorities who take the view that traffic must accommodate itself to the existing roads. These reactionary ideas have found expression in resolutions favouring restrictions upon the use of bicycles, autocars and other forms of rapid traffic. These attempts to retard progress are unlikely to commend themselves to Parliament and to the public. The roads must be adapted to meet the demands of the traffic—that is to say, the existing roads must be widened where necessary, and new ones, suitable for rapid traffic, built . . . Unfortunately, under the existing system of administration, little can be done to provide better and wider roads. Since the abolition of the Turnpike Acts, no new main roads connecting distant towns have been made. The machinery for widening existing roads is so expensive and so cumbersome that very few local authorities can be induced to put it into operation on any large scale. Under all these circumstances, the Roads Improvement Association has determined to bring organised pressure to bear upon Parliament and the Government to amend the existing system of administration. And the moment is a propitious one. There is little doubt that the present system of local taxation will, in any event, be revised, and the relations existing between the central and local authorities reviewed, upon the issue of the final report of the Royal Commission on Local Taxation. The opportunity will therefore be afforded to ear-mark a portion of the Imperial subventions to local rates for the purposes of road maintenance, and to establish a certain measure of central control. . . . . A general improvement can be most readily affected through a central department directly responsible to Parliament. The maintenance of roads is the only important duty of national importance which local authorities are now left entirely unaided to discharge."

New Companies.

Ashover Stone Co., Ltd.

Registered May 3rd to acquire the business now carried on at Ashover, Derby, by Mrs. M. A. Wigglesworth as the Ashover Stone Co., and to carry on the business of quarry owners, stone merchants, &c. Capital £2,000 in £1 shares.

Portable Building Co., Ltd.

Registered April 30th to acquire the business of the Portable Building Co., and to carry on the business of builders of portable buildings of every description, general engineers, bricks makers, builders, contractors, &c. Capital £10,000 in £1 shares.

New London & County Building & Estates Co., Ltd.

Registered May 7th to acquire any freehold, leasehold and copyhold property and buildings, and to carry on the business of builders and contractors, estate agents, dealers in building materials of every description, capitalists, &c. Capital £5,000 in £1 shares. The first directors are G. Porter, C. W. Scott, P. C. Webb and F. Summerfield.

Bellerby Syndicate, Ltd.

Registered May 4th to adopt an agreement with J. W. Gibson and others to purchase, deal with and turn to account any freehold, copyhold and leasehold lands and buildings, and to carry on the business of builders and contractors, &c. Capital £1,000 in £1 shares. The first directors are R. W. Simpson, T. Metcalfe, F. H. Bennett, J. Airey and J. Peterson.

Blyth Brick Co., Ltd.

Registered May 3rd to acquire the business of brick, tile and terra-cotta makers now carried on by the Blyth Brick Co., and to carry on the business of brick, tile and terra-cotta manufacturers and merchants, cement manufacturers, clay workers, &c. Capital £10,000 in £1 shares. The first directors are D. Crichton (managing director) and R. T. Gray. Registered office: Link Road Works, Blyth, Northumberland.

John Horsford & Co., Ltd.

Registered May 6th to acquire the business, property and effects of the late firm of J. Horsforth & Co., and to carry on the business of manufacturers of and dealers in bricks, tiles, pipes, flints, manures, coal and coke merchants, builders and contractors, &c. Capital £20,000 in £1 shares. The first directors are Mrs. E. Seager, Mrs. E. Chrisfield, Mrs. M. A. Ersdaile and M. H. Seager. Registered office: The Brickworks, Oare, Kent.

Abertbaw Hydraulic Lime Co., Ltd.

Registered May 1st to acquire the business now carried on at Porth Kerry, Glamorganshire, as the Aberthaw Hydraulic Lime Co., to adopt an agreement with E. T. Ferrier, T. R. Thompson and I. Alexander, trading as the Aberthaw Hydraulic Lime Company, and generally to get and make marketable building stone, limestone, &c. Capital, £2,500 in £1 shares. The first directors are I. Alexander, T. R. Thompson, E. T. Ferrier and J. B. Ferrier.

TRAIN BRAKE REFUSED TO ACT.

The failure of a brake to work promptly caused rather a nasty accident at St. Pancras Station last week.

A train from Luton came up to No. 6 platform, and the driver applied the brake, but it refused to act. The consequence was that about a dozen passengers sustained cuts and bruises, two of the number being so seriously hurt that they had to be taken to the Royal Free Hospital.

Such Accidents as these frequently happen, and all who travel are liable to them.

Every Subscriber to THE BUILDERS' JOURNAL should avail himself of the advantages of our Insurance Schemes, which provide against such risks.

There are **Three Schemes of Insurance** connected with our Papers, guaranteed by the OCEAN ACCIDENT AND GUARANTEE CORPORATION, LTD., and all readers who have not yet sent for particulars should do so at once.

There are many readers whose names and addresses we do not know, as they subscribe to the Journal through the bookstalls or newsagents. EVERY READER WHO HAS NOT RECEIVED ONE OF OUR INSURANCES SHOULD WRITE AT ONCE FOR PARTICULARS.

Scheme No. 1 is a free Accident Insurance of **£500.**
FREE.

Scheme No. 2 is an Accident Insurance of **£500,** giving the following additional advantages:
Premium, 1/-
£250 for Permanent Total Disablement.
£2 10s. 0d. per week for Temporary Total Disablement.

Scheme No. 3 is an Accident Insurance of **£1,000,** with these additional advantages:
Ordinary Risks, Premium, £3/-/-
Hazardous Risks, Premium, £3/10/-
£500 for Permanent Total Disablement.
£6 per week for Temporary Total Disablement.
£1 10s. per week for Temporary Partial Disablement.
£30 Annuity.
£3 per week during confinement from such illnesses as Diabetes, Scarlet Fever, Carbuncle, &c., &c.

The Condition attached to these Schemes is that they only apply to Annual Subscribers.

If these schemes interest you, write for full particulars to

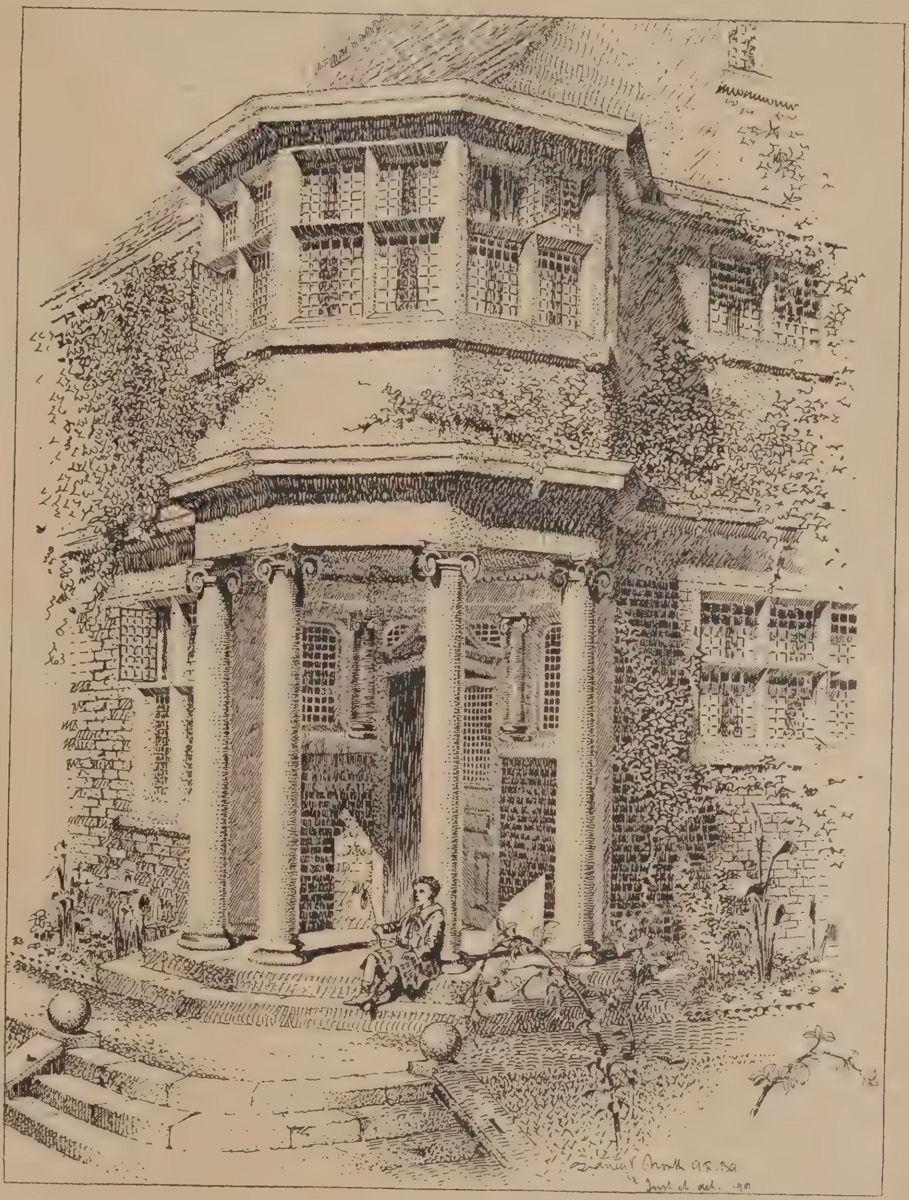
An Architectural Causerie.

Madame Du Barry's Hotel. THE French Government seem to be as indifferent as our own to the value of historical buildings. It appears that the hotel of Madame du Barry at Versailles, which is at present in the occupation of the commandant of the garrison, is about to be put up to public auction by order of the administration of public lands. Apart from the interest attached to the building as the residence of a person who played an important part in the contemporary history of France, it is also valuable as a work of art, the front having been designed by Jacques-Ange Gabriel (1719–82), the architect to the French Admiralty, who built the old garde-meuble, or storehouse, and the military school of Paris. To destroy a fine building, says a French contemporary writer, is as blamable as to destroy a fine picture or a beautiful statue, considering the rarity of such buildings. The Commission des Monuments Historiques appear to have taken no steps to prevent the possible demolition of the building.

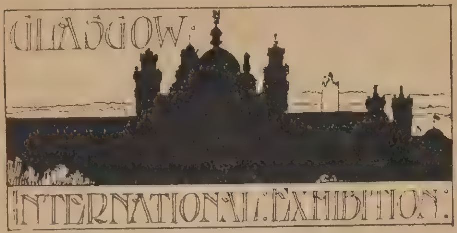
Changes in the Strand. THE changes which have already been effected in the Strand, those now in progress, and those to be made in connection with the new thoroughfare, will combine to give this world-known artery a totally different aspect. The neighbourhood of Charing Cross preserves its accustomed appearance, but a little way eastwards one sees the huge new front of the Hotel Cecil (erected from Mr. Sawyer's designs) now approaching completion; almost opposite, work is in progress for the addition of a tower to the Adelphi Theatre; at the bottom of Catherine Street a great clearance has been effected preparatory for the new street; while further east the graveyards of St. Mary-le-Strand and St. Clement Dane's are being cleared in order to give additional width to the thoroughfare. All these alterations have greatly changed the appearance of the Strand, which is now of a splendid width in several parts. Another improvement is to be effected by the construction of a new northern approach to the Savoy Hotel. The narrow precipitous approach by way of Beaufort Buildings is to be widened from 23ft. to 40ft., and levelled up, so that the hotel entrance will be level with the Strand instead of far below it. The front of the hotel is to be advanced 20ft., and, with the 17ft. gained by the widening of the Strand, this will bring the hotel about 35ft. nearer that thoroughfare. The houses facing the Savoy Theatre have been acquired, and will be replaced by an extension of the hotel and a spacious courtyard. It is possible that ultimately the hotel may have a frontage on the Strand, like the Cecil, which was a pet scheme of Mr. D'Oyly Carte.

Metal Construction. IT is an architectural axiom that any material can be used for building, provided it is suitable; and there is consequently no justification for opposing a new material simply because it is new, because it is unlike what has hitherto been employed. In tracing the evolution of architectural forms we find that the earliest are direct copies from Nature, the form gradually altering—for the better or worse—according to the abilities and environments of its adaptors. We find, for instance, that in the early dynasties of Egypt the lotus column very closely resembled the lotus bud, with the bands of papyrus and slender stems which constituted the prototype of what we now see at Luxor and Karnak. But in the later dynasties the form became debased, just as in Roman times Greek forms were debased, and features were exaggerated out of all regard to their original derivation. It will be noticed, however, that natural forms were first copied in wood; that wood forms were preserved in stone (such as the wedges in metopes); and, following the same sequence, stone forms might be continued in metal. This, however, is not defensible, as the qualities of the one material are totally different to the qualities of the others. In our own day we have witnessed the increasing employment of steel and iron in buildings and bridges, a change regarded by many as utterly deplorable. Novelty is no criterion of excellence; but iron and steel have proved eminently suitable to the needs of the architect and the engineer, and the fact that the bulk of the metal construction around us is so devoid of beauty does not argue that the fault lies with the material: rather it is with its users. Iron bridges are generally ugly, but it does not follow that they are bound to be so. It is not probable that metal will ever entirely replace stone as a building material, because of its conductivity; but that it will be still more extensively used in the future is certain. This can be legitimately done, and it is futile to abhor the material because of the abuse to which it is subjected.



DESIGN FOR A PORCH. BY SIDNEY V. NORTH, A.R.I B.A.

A Porch Design. THE porch by Mr. Sidney V. North, A.R.I.B.A., illustated on this page, is intended for the garden entrance to a small residence in a situation where it would not be exposed to winter winds. The columns, cornice, &c., are intended to be in pitch-pine, the carved caps in mahogany and the whole of the remainder painted white.



With Special Sketches by J. Jeffrey Waddell.

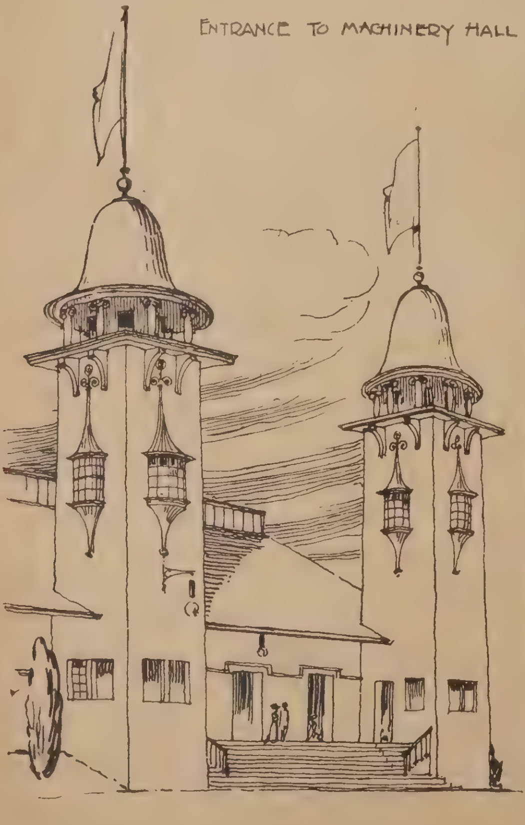
(Concluded from p. 294 of No. CCCXXVIII.)

THE great Machinery Hall represents most vividly the active forces of modern life. It is connected with the Industrial Hall and the Art Galleries by a covered corridor called the Grand Avenue. This is 1,000ft. long, 75ft. wide and 40ft. high, formed of semicircular laminated wood arches carrying a glass roof supported on iron astragals.

From the end of the Grand Avenue a roofed-in bridge, crossing over Dumbarton Road, leads direct into the Machinery Hall. This is a rectangular building, covering 175,000 sq. ft., and containing about 250 stands of machinery and ironwork under one roof. The arrangement of the hall is by Mr. Thomas Young, M.I.M.E. The floor space is divided into sections by frequent passages running at right angles lengthwise and crosswise, so that every stand is easily accessible, and a vast multitude of visitors may inspect the machinery at the same time without crowding or obstruction. Galleries also run overhead and permit an extensive bird's-eye view from above.

The plan of the Machinery Hall is admirable, and could not be improved upon; but the metal work is devoid of the interest of beauty, and one sighs for the combination of constructive and decorative skill which constituted the steel girder construction of the roofs, staircase and galleries of the Grand Palais in Paris, an example of twentieth-century architecture of the first order. The importance of money in this connection must not, however, be forgotten. Such matters as plan and construction are, after all, of minor importance in buildings of this nature compared with external effect, and in this respect they may be said to be entirely successful.

Only one structure in the Exhibition is permanent—namely, the new Art Galleries, which are, in a sense, a legacy from the last Exhibition. Messrs. Simpson & Allen were the architects. A start was made with a sum of £40,000, representing the surplus profits of 1888, and the buildings have been completed at a total cost of about £250,000. The materials used in these galleries are the handsome Locharbriggs red stone outside, and the Glasgow Giffnock white stone for the interior. There is a central court and two wings east and west, with galleries running all round, the whole very ample, spacious and dignified. Mr. F. H. Newberry, the headmaster of the Glasgow School of Art, has arranged the exhibits of sculpture and architecture, and Mr. R. W. Allan has done similar duties in regard to the pictures. The central court (125ft. by 56ft.) is devoted to sculpture, and the special feature of the collection is that it is the first representative exhibition of British sculpture ever held. There are examples of foreign artists—M. Rodin, for example—but the collection is essentially British, and it contains most of the finest work, either in originals or copies, that has been produced in recent years, No one interested in British art should miss it. Of the two wings (each 102ft. long), the western is devoted on the ground floor to Scottish antiquarian and historical objects; the eastern to architecture, art objects and photography.



ENTRANCE TO MACHINERY HALL

· CORBEL · UNDER · PILASTERS ·

Of the sculpture exhibited the bronze statue of Queen Victoria by Mr. George Frampton, A.R.A., which is temporarily situated at the entrance to the galleries, on its way (or out of its way) to Calcutta, draws the greatest attention. Of considerable interest, too, in view of the sculptor selected for the Queen Victoria Memorial, are the two examples of the work of Mr. Thomas Brock, R.A., namely, his statue "Eve" and his bust of the late Lord Leighton. Mr. E. Onslow Ford is represented by half a dozen pieces, including his "Shelley Memorial," the recumbent figure of the poet drowned, his Huxley, Irving and "Echo." Mr. Alfred Gilbert, R.A., has two original statuettes, "Perseus Arming" and an "Offering to Hymen," both lent by Mr. J. P. Heveltine, as well as a bronze head, the property of his fellow Academician, Mr. Luke Fildes. An attractive show of work by Mr. Andrea C. Lucchesi demands attention; it includes five life-size female figures, and two similar-sized busts called "Life's Coronet" and "Innocence" respectively. A plaster model of Mr. Hamo Thornycroft's Oliver Cromwell, now established at Westminster, is accompanied by his portrait busts of Sir James Chance and Sir George Stokes, and by two imaginative bronze statuettes. Mr. A. M'Farlane Shannon's statue of Lord Kelvin has been lent by the Glasgow Philosophical Society, and is appropriately placed in the Exhibition on the river from which Sir William Thomson took his title. Altogether there are more than two hundred and fifty pieces in this hall, a fair number of which come from France.

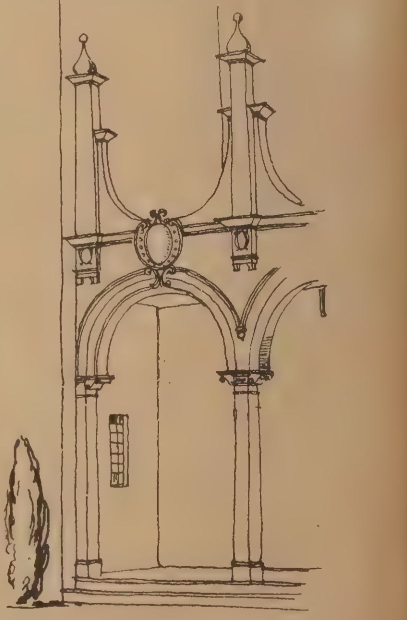
A little building known as "the Squireen's Cottage" represents Ireland. The house itself is charmingly situated on a slight elevation in front and to the left of the Concert Hall. It was designed by Mr. T. Manly Deane, and represents a small country house of Georgian period, at Malahide, standing on its own grounds. It is a low double-fronted house, with white concreted walls, rounded bay windows and thatched roof. The "friendly" aspect—to borrow a German term—of this modest structure makes it conspicuous. The interior is divided into several several rooms, which are devoted to different branches of Irish industry. A single exhibitor in Dublin has forwarded beautiful specimens of fourteen different kinds of Irish marbles, all polished, and there are some fine slabs and columns of Galway granite. The specimens of household furniture from Killarney deserve recognition.

Japan, France, Austria, Denmark, Morocco, Mexico, Persia and the United States are also represented, but no pavilion represents Germany, which is to be regretted.

In the two huge restaurants on the slopes of Gilmore Hill, clever and effective as they are in general mass and outline, the details are at once poor in conception and coarse to a degree. With this even the inexpert observer cannot but be struck if he compares them with the Van Houten building opposite. Designed by Mr. A. N. Prentice somewhat after the manner of an Old English manor-house, though very freely and characteristically treated in harmony with its function and manner of construction, it is especially notable for the refinement and care with which its details have been worked out, and is quite the best piece of architecture among the minor buildings. This little pavilion is cream coloured, with ornament picked out in gold.

The Indian Theatre, of which we give an illustration, is quite a small structure, and relies mostly for its delightful effect on the stencil work which adorns its front.

The arrangements for lighting the Exhibition merit a word. The system which has been adopted in the grounds was tried in Paris last year, and has since then been greatly improved. Mr. Buchanan has been in charge of this installation, and its effect is to make the outdoor part of the Exhibition better lighted than anything of the kind before. It consists of 140 columns, each carrying a shadowless lantern containing a three-light cluster of high-pressure Kern burners, consuming 31½ cubic feet of gas per hour, each cluster giving a light of over 1,000 candles. Twelve columns each carry three shadowless lanterns, with three-light clusters of Kern burners, and ten have five shadowless lanterns, each with three-light clusters. The total candle-power of the installation is 237,000. The gas is supplied by the Glasgow Corporation, who have laid special high-pressure mains for this purpose, and the work has been done by the Welsbach Company. The motor power is supplied by a water-motor plant (by Messrs. Keith, Blackman & Co., Ltd., of London) capable of compressing 6,000 cubic feet of gas per hour. The noise of the gas as it rushes into the burners makes the system unsuitable for indoors—at least in small interiors—but the cost is much less than that of electricity, and the light is more diffused. Electric arc lamps are, however, employed for the interior lighting of the buildings.



PORTION OF COLONNADE TO MACHINERY HALL.

Mr. James Miller, I.A., the architect of most of the Exhibition buildings, is thirty-nine years of age, and is a native of Perthshire. He served his apprenticeship with the well-known architect Mr. Andrew Heiton, of Perth. Having passed some years in Edinburgh, Mr. Miller in 1888 entered the service of the Caledonian Railway Company, where he remained till the end of 1892, immediately thereafter commencing business on his own account. The principal buildings erected from his designs are Belmont Church, Hillhead;

Prince's Pier Station, Greenock; and Gourock Station. Everybody in travelling by steamer must have been impressed with the admirable taste displayed in the designing of these fronts, while strangers are every summer heard to speak in the highest terms of the details connected with these conspicuous Clyde landmarks. Mr. Miller was also architect of the picturesque station at Botanic Gardens and Kelvinbridge Station, on the Glasgow Central Railway. Among other notable buildings he has designed may be mentioned the Glasgow Subway Station at St. Enoch Square, Kelvinbridge Mansions, Clydebank Municipal Buildings, Town Hall, and Public Baths, Library, &c., together with several churches and mansions in Glasgow and throughout the country. Mr. Miller has been recently appointed architect for the reconstruction of the Glasgow Royal Infirmary.

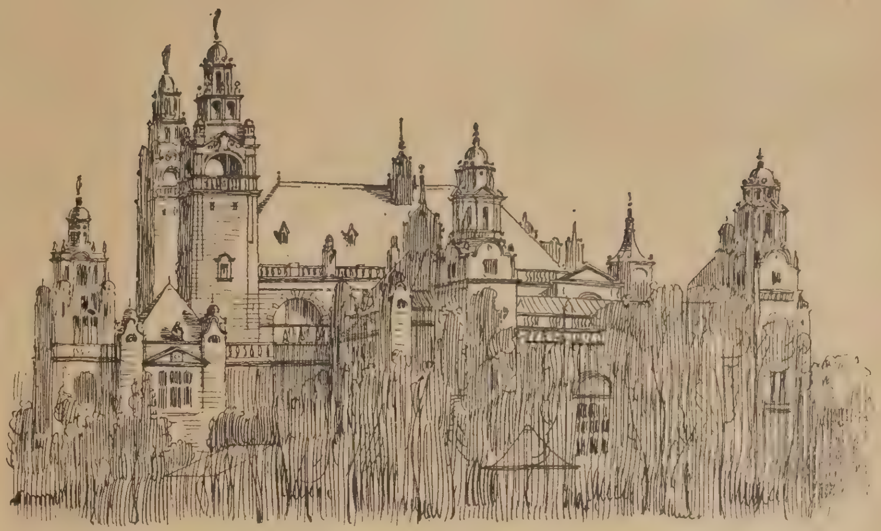
The contractors for the main Exhibition buildings have been Messrs. William Shaw & Son, of Commerce Street, Glasgow. As wrights and contractors, the firm has been long established. Mr. William Shaw died in 1872, when his son, Mr. Robert Barclay Shaw, succeeded him, then only nineteen years of age. The business was started as long as fifty years ago in Eglinton Street, and during the past quarter of a century Mr. Shaw has carried out numerous big works. His crowning achievements have no doubt been his erecting of the two International Glasgow Exhibitions, he having been responsible for the construction of the 1888 buildings as well as the present structures. It may be mentioned that in 1888 the main buildings, including the machinery annexe, measured 474,500 sq. ft., and covered about 10 acres. The 1901, including the Fine Art Galleries, cover an area of 20 acres. Mr. Shaw's firm used about 5,000,000 bricks and 750 tons of iron in the 1888 structure, also 700,000 cubic ft. of wood, 70 tons of nails and 250,000 sq. ft. of glass. Besides erecting the Industrial Hall, Machinery Hall and Grand Avenue, Mr. Shaw has this time also been entrusted with the building of two bridges over the Kelvin, the covered way at Bank Street, the Royal Bungalow, Bachelors' Café, Bodega, the bridge over Dumbarton Road, the agricultural section, the Concert Hall, water chute, two kiosks in front of the Art Gallery, and various tea rooms.

The engineer and electrician of the Exhibition is Mr. Thomas Young, M.I.M.E., M.I.E.E. He is one of the busiest men in the city of Glasgow.

Mr. Charles Carlton, sole member of the old-established firm of Charles Carlton & Son, St. Vincent Street, was entrusted with the painting and decorating of the Industrial Hall. Some time ago Mr. Carlton was successful in being appointed to carry out an important decorative scheme within the Municipal Buildings, and among the various large contracts secured by him of late was the painting at Woodilee Asylum. He is a Fellow of the Incorporated Institute of British Decorators.

Mr. Robert Whyte acted as master of works, his assistant being Mr. D. M'Intosh.

TOWER, MACHINERY SECTION.



THE FINE ART GALLERIES FROM BEYOND THE KELVIN.

REGISTERED ARCHITECTURE.*

By BULKELEY CRESWELL.

It is two years since I had the honour of addressing you in this room, and I feel somewhat apologetic when I remember that the subject I am bringing before you to-day might have been treated just as appropriately when I was here before. The proposal to register architects, like many other fatuous contentions, we have always with us, and the best that is to be hoped by those who are opposed to such a scheme is that it will remain in the state of being a proposal, and never actually be embodied in any rules regulating the practice of our profession. I am not aware of any reason why this subject should be dealt with at this particular date except a reason which is entirely personal, the reason being that a certain professional journal called attention to the subject, no doubt with the idea of enlivening its pages by resuscitating the slumbering polemics which this subject is notorious in provoking. I have been a good deal roused by what seems to me to be the extraordinary short-sightedness, and the lack of all those ambitions which one would expect of a profession which likes to call itself an art with a big A, apparently characterising those who lend the weight of their approval to the cause of registration. What I have first noticed as being essential in the regard of those who deal with this subject is that they look to the professional and material aspects of the subject, and seem to disregard altogether what to me is essential to the welfare and dignity not only of the practice of architecture but of any profession whatever. There is naturally a professional side to the question—the side which involves such questions as whether or not we shall be able with dignity and self-respect to make a living—and this, of course, must be considered; but it is certainly not the side which should be emphasised and made the essence of questions involving the welfare, discipline and conduct of the profession. My remarks must, therefore, fall under two heads, which may be described as the material, *i.e.*, the professional or trade, aspect of architecture, and with the ideal, that is, the personal, and I may say moral, aspect of the question; and in doing this I want to ask your toleration if I express myself with the emphasis I feel, and ask you to remember that I am not professing to be any wiser or more experienced than other people. I have frequently been called to task for expressing views which do not coincide with those of men of greater age than myself. I am weary of this; especially that I cannot make these men younger. This is not a matter of astonishment nor of regret to me in itself; because men whose minds grow old are at the stage of decay, and no man ever raised so paltry a retort unless he were desperately hard pressed for an answer. I am impatient of "Wait till you are as old as I am," for I take it that nearly everything that has been done in the world that has left its mark—that is making the world better—if it has not been done by young men, has been brought about by the persistency in men in remaining young. It is characteristic of youth, not of age, to make sacrifices and take risks. I take it that the essence of the "prudence" and wisdom of age is the absence of enterprise and courage, which has been reduced and disintegrated by the wearing and blunting process of living.

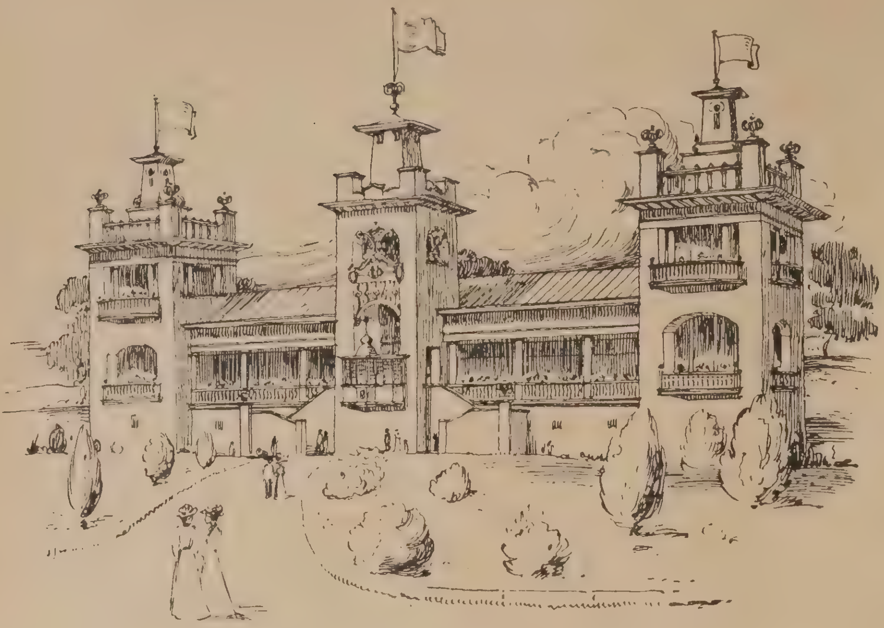
It is hard to have any reverence for that pennywise quality of wisdom such as we may imagine would conduct a provincial retail tradesman to a worthy old age and into which I, for my part, might beget a dread of lapsing if I were a largely equipped family man and the house full of measles. This sort of wisdom is entirely negative—it is a residuum, the waste of a life conformed to convention; it has no least affinity to the wisdom of Carlisle, Emerson, Ruskin; it has no fire, it is the dust and ashes of burnt-out convictions and ideals. We see these wise old fellows, with their knuckles on the table, at ponderous self-congratulatory functions emitting platitudes of expediency which a wholesome young man would be ashamed to utter. Call it "wisdom" if you will, yet it is not admirable but eternally lamentable. It examplifies that each has extinguished such fires as he ever had, and had pulled down his flag. There is, indeed, nothing reprehensible in this passive failure until it is made an ideal. I for one intensely resent that it should be accepted as an ideal, and I believe that we all here have that resentment.

I do not think that anything is more conspicuous of men of force of character, who have said things that the world is better for, or done things that future generations have loved to contemplate, than their perennial youth.

And there is another reason why on this occasion and in this place I have no objection to state my views with the emphasis with which I naturally feel inclined to endorse them, and this is the fact that the members of the Birmingham Architectural Association are supposed to belong to the younger branch of the profession, and I also am in the same rank, and I do not see why we should not discuss such subjects among ourselves, without the least suggestion of any reverence for or belief in the experience of other people. I have yet to learn that in any of the essential motives which direct mankind experience plays any very praiseworthy or indeed very considerable part. When I shall come to that part of my remarks which deal with the ideal aspect of registered architecture as I have named it, I shall have another apology to make, and that is to ask you to remember that you are not supposed to be listening to a sermon.

---

* An address delivered before the Birmingham Architectural Association on March 22nd, 1901.



THE PRINCE'S RESTAURANT, GLASGOW EXHIBITION.

I do not propose to spend much time in considering the Bills for proposed registration, but it has been a matter of surprise to me that there have been no less than five Bills brought in to the House of Commons in the ten years following the year 1888. These Bills are in essence identical, the last ones, however, being more concise. The history, scope and purpose of this Bill, for all in essence are one and the same Bill, may be summarised as follows: On April 6th, 1886, a meeting of architects was held in Freemason's Tavern, in London, attended by the members of the Institute, Society of Architects, and by practitioners not connected with any society, and a committee was then formed, called "The Architect's Registration Committee," to give effect to the following resolution then and there passed :—

> "That it is the opinion of this meeting that instructions be given to the Committee to consider the means necessary to obtain an Act of Parliament making it compulsory for all architects to hold a Government diploma."

This committee was composed of Institute members, members of the Society of Architects, and independent members, who set to work and eventually framed the Bill subsequently laid before Parliament.

The advantages claimed as arising from registration have been briefly stated to be as follows :—

Closing the doors to incompetent men.

Raising the standard of the profession.

Obtaining the confidence of the public and State recognition.

The provision of a general council and branch councils to administer the Act, composed of members of existing architectural bodies, as well as members nominated by the Privy Council and registered practitioners.

A provision as to the appointment of registrars, and the necessary machinery for registration.

The qualification for registration at the commencement of the Act, which includes all members of existing architectural bodies, and such other persons as could show, to the satisfaction of the council, that they were actually practising architecture ; and afterwards only such persons as have passed a qualifying examination.

The provision of an examination either by the general council or some already existing architectural body.

And, lastly, fines upon unqualified or unregistered persons practising as architects, and a provision as to their inability to recover charges for professional services rendered.

It has been further claimed that the first effect of a Registration Act would be to put a stop to any further increase in the number of incompetent practitioners, and thenceforth they would become a diminishing quantity.

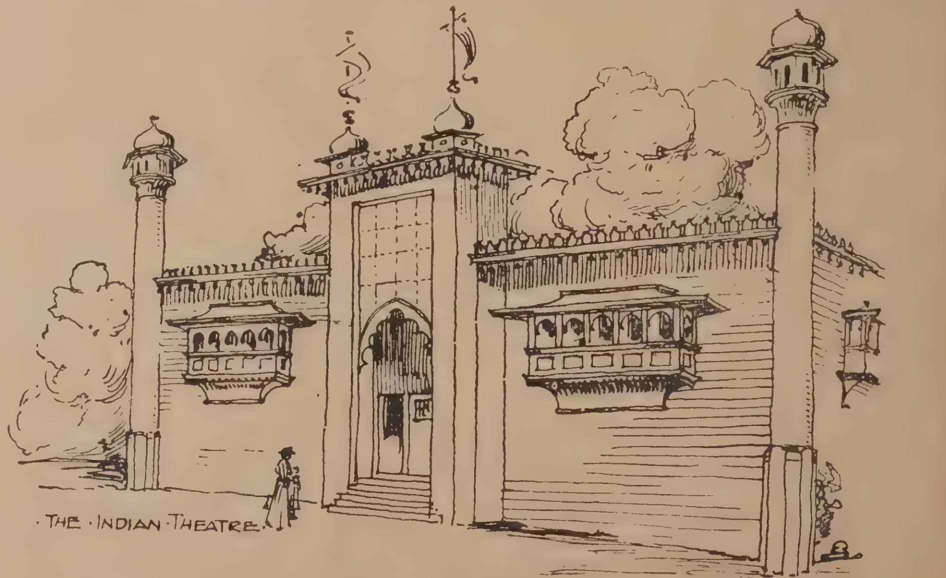
In the present it would mean that every man practising architecture should be duly enrolled in an official register under an Act of Parliament, and be duly responsible for his professional actions, and that no one be allowed to practice until he is duly enrolled.

In the future it means that no one be allowed to practise architecture until he is duly qualified, and has been found so by undergoing a qualifying examination.

The successive Bills prepared and brought in by various members of the House of Commons, among whom the names of General Goldsworthy and Mr. Atherley Jones are conspicuous, and among whom the name of Mr. Justin M'Carthy appears in connection with the Bill brought in 1889, are dated respectively 1888, 1889, 1890, 1895 and 1898.

After the first reading of the Bill in 1890, the Royal Institute of British Architects laid before the House of Commons a statement or petition against the second reading. The main objections put forward in this statement were that the Bill was not promoted by the Institute, which was the only body representative of the profession of architecture holding the authority of a royal charter ; that the Bill only provided against an unregistered person calling himself an architect, and, therefore, that a man calling himself a surveyor, engineer, builder, auctioneer, or, for the matter of that, pastrycook or chimney-sweep, would be free to practise architecture ; and the Institute further professed a healthy dread of their rivalry (which in the case of the pastrycook we may realise was wholesome and natural) ; that the fact of a man having been in practice for a certain number of years (the 1890 Bill fixed the period at five years, but it was reduced to two in the 1898 Bill) did not imply competency. The gist of the matter was that the Institute could not tolerate any such radical measure emanating from other invention than their own ; and that as the Bill enabled an incompetent architect to enjoy the privileges of registration, and would not preclude anyone from practising as an architect as long as he called himself by some other title, such as "builder designer" or "building agent," the result of the Bill would be chaotic, or, at any rate, that it would only contribute to the supposed anomaly it proposed to remove. These are all, no doubt, perfectly sound objections, but this statement of the representative body distinguished by a royal charter betrays demerits and disabilities in the profession which had been better kept underground. The point of demerit is that the profession avowedly has no objection to make to a scheme of registration which is not entirely based on considerations of personal benefit to the practitioner and the material welfare of the profession. Not a word or a sign appear which suggest that this representative body immaculated by its royal charter has any ambitions of architecture apart from the possibilities it holds out to the practitioner to grow fat in professional prosperity and achieving the dignity of a person of affairs. The admission of disability lies in the acknowledgment clearly implied and to be inferred that architects have entirely failed to impress the public with the good taste and merit of their designs and their general ability over and above that of the surveyor, builder or auctioneer who may put his services at the public's disposal in the rôle of architect.

I do not, however, propose to examine and criticise the clauses of the proposed Registration Bill. We may leave it with a parting glance at the possible picture it would provide of a well-qualified pastrycook, unregistered, hot in rivalry as a practitioner with an entirely incompetent, but registered, architect. I do not propose to take up the points of the Bill seriatim, because the principle is untenable to my thinking, and because, having in view the result, the restriction of freedom of thought and sincerity of expression, no Bill would be otherwise than disastrous to architecture considered as a profession only, to say nothing of the vast evil consequences it would have upon architecture in its highest sense as a fine art and as one of the most eloquent mediums for the expression and popular cultivation of taste and feeling that exists. As far as it is possible to decide, the object of the Society of Architects in so persistently urging the claims of this Bill seems to be based on some idea of adding cumulative



weight to the personal importance of members of the profession. This seems to be the general prevailing motive of those who are in favour of registration. The question they seem to ask themselves is, "Will registration lend itself to the impressiveness of my personalty with the public; will it increase the attitude of obligation in my client; will it augment the grudging 5 per cent.; will it raise me above my present social standing; and will it enable me to settle down—*i.e.*, to go impressively to church on Sundays with a silver-mounted umbrella, with wife and olive branches with enormous hymn-books, in full parade of their Sunday wardrobes, and to return home none the less impressively to a terrific smell of cooking at one o'clock? Will registration do these things for me?" One perceives that the answer has been in the affirmative. It is no use blinking the fact: rearrange and supplant the humdrum ideal as you will, this is the ideal of the five-per-center, and this the ideal which is one day to carry the tyrant Registration to the throne. The attraction which has made registration popular is no more than the attractiveness of a swag-bellied professional prosperity.

I do not say that the aspirations of all those who press the claims of registration are moved by any such ungenerous motives, nor that all those who have passed the examination of the Royal Institute of British Five-per——Architects, I mean—view the process as a means of hastening to the achievement of a rapid domesticity, but it would be ridiculous to deny that the great inducement to young men to enter for the examination is the qualification implied thereby in the public mind, and the act does not constitute an approval of the system, the real issues of which have no bearing on the decisions of the intending associates.

Then there is the public. It is constantly put forward on behalf of registration that it would secure for us the confidence of the public. I find it very hard to approach this contention with any patience. I cannot help detecting here also the special plea of the professional paunch and frock coat. Unless it is that we aspire to the dignity of the professional paunch and frock coat, of all confidences why aspire to the confidence of the public? I do not think that it is an exaggeration to say that in all matters involving the processes of the artist, or calling for the exercise of creative thought, the applause and approval of the public constitutes a very serious condemnation. The public praises and applauds what is specious and meretricious.

To him who assumes to be exponent of any art, or whose sphere is of creative thought, there can surely come no such unequivocal stamp of vulgarian and charlatan than this approbation in the eyes of the public. It may be stated as a general truth of all men of such calibre, that in so far as they have the confidence or approval of the public it is a proven token of shallowness of thought and vulgarity of method. That dark suspicion of speciousness which popularity throws is rarely at fault; its test is so searching that though the professed critic be unable to confirm the implication of public applause, the years will prove his error, and posterity know that their excellency is illusionary and ephemeral, and not of classic quality.

In architecture it is a fair and almost infallible proof of the true qualities of essential irremediable badness of a design that it shall provoke the applause of the public, and if a good design that it is regarded with popular coldness and distaste. This rule, of course, does not apply to traditional buildings, where quite other issues than those of architectural design direct the people's shout; but for modern buildings that aspire to architectural qualities this test is so far infallible that if we can gauge the attitude of the public towards a design we know with some exactness its comparative worth. Any cultured person may have personal tastes and prejudices which make him uncertain whether, for instance, the Houses of Parliament or New Scotland Yard is the better building; but with this test, he may decide at once that, whatever his own feelings may be, New Scotland Yard is much the best design because the public much prefers the Houses of Parliament and gave wild approbations to the design when the building was first put up. The attitude of architects should not be that of desiring the confidence or approbation of the public, but rather the reverse. The thinker and the man of artistic convictions, if he cannot altogether forget and ignore the existence of the public, will regard it always in the figure of a hulking mongrel cur gorging, with concentrated attentiveness, the offal in the gutter; and will remember, as was once pointed out by Mr. George Moore, that it is his duty and his privilege on all and every possible occasion to "kick the brute in the ribs."

I cannot conceive anything more humiliating to the ambitions and aims of a true artist or worker in any of the spheres of creative thought than to find himself the victim of the applause of the public—that is to say, to find himself the victim of the applause of the public by reason of his work; to know that his hard earnest efforts are so wanting in subtlety or original thought that they attract and amuse a thoughtless casual public. It is, of course, possible that a man may find a certain pleasure, and it is certain that many people *do* find a very great pleasure and satisfaction, in becoming a popular figure, a person of whom the public is ambitious to know what he has for breakfast and what he smokes.

This public concession to architects has been greatly lacking since Sir Gilbert Scott died, which speaks ill of our hold, of our endeavours, on the popular in this paragraphing age. But however sincere the flattery of public condescension may be it does not amount to any plea why the profession should shape its ends to this much mooted "confidence."

If we admit that in spite of all this the registration of efficiently qualified men is a thing which is desirable, the question then arises, How is this selection to be made? It cannot be arbitrary; it cannot be left to any body of persons to say that the ideals or acquirements of this or that architect entitle him to practise architecture, and that the attainments and abilities of another do not so entitle him. It is pretty clear that qualification, the process of eliminating the unsuitable or inefficient, can only be achieved by examination. Now what does this imply? What does it involve? It is obvious that no man can be tested by examination in that quality which the votaries of registration seem most anxious to secure and hold. The quality I refer to is the certitude of exacting full 5 per cent. from a grudging public. Even if it were possible so to examine men, the examination would obviously stultify its own end, for it would in effect select only those men who were best qualified to starve one another. The examination, if it were to exist to any real purpose at all, would have to make a test of the candidate's experience, culture and taste, and *of his ability to think.* I take it that these are the qualities upon which true proficiency in the practice of architecture is based. Unfortunately, the qualities which examination deals with are power of memory and knowledge of other people's experience—by which I mean the theoretical learning and knowledge acquired from text-books. I think we must all be agreed that there is much to be desired and much to be amended in the educational schemes in vogue in this country. The whole tendency of modern education is to cultivate the memory, and the memory is cultivated at the expense of the power to think. There is this strong uniform influence in every course of examination—that they tend to shape all minds to the same conventions of thought and the same intellectual methods. This is an influence in diagonal antithesis to those which promote creative thought and inspire imagination; and it is an influence which, more than any other, must devitalise the poor,

CANADIAN PAVILION.

fragile, twitching carcase of architectural enthusiasm in this country. An examination to qualify architects would reduce to an absurdity the established theory of education in this country—itself an absurdity. If we consider it, a magnified parrot would do not discreditably at an English public school and stand a chance of, perhaps, taking a prize or two back with him to his cage at the end of terms; and as his repertory increased he would make good marks in most of the public and professional examinations. By what process we have come to regard a capacity for retaining facts as a physical desideratum, or an admirable acquirement, it is difficult to conceive. Of our own experience we may all recognise how opposed is the habit of retentiveness of data to fertility of mind and a ready imagination. The faculty to command data is of little use or purpose. Every man remembers the facts involved of the routine of his daily work, and to hold a multitude of facts which are not within his usual need is to usurp some of the finer processes of thought. True power lies in the use of those essential facts; and a man who has a good handbook in his pocket and knows how to use it is vastly better equipped than another who has the data it contains in his mind, granted that their mental ability and vigour was in the first instance of the same calibre. Even if the test of memory, which is the test chiefly comprised in examination, were a sound and truly discriminating test in such positive subjects as law and medicine, it would still remain utterly fatuous to apply it in the case of architecture. The exercise of memory of data and the habit of committing to mind exact facts constitute a mental attitude the most hopelessly removed from that by which architecture is to be purified or dignified. In every building each moulding drawn and each nail driven for the reason, and by the mere knowledge, that it has been so done before is a contribution to the sarcophagus of architecture.

It is the power to think and feel only which constitute the intellectual qualities by which a man becomes an individuality and leaves the world in any case better or wiser than he found it. Any fool can remember things. We may say that thought and memory are in antithesis. A man who acquires the habit of memory loses the ability to think. We most of us have cause to regret the processes of our education, I think. My own education, as I remember, consisted in being required to remember facts and data, and I recollect that the sense of feeling was always supposed to be the chief of the receptive faculties. I may say, without exaggeration, that I took the bulk of my education through the skin, and it is a great satisfaction to me at this time to know that, in spite of all, I conquered in the end, and that I never learned to remember anything except by accident or when taking it unawares. I think there was hardly an exception to this, but I still retain a few items of historical data which burden my mind still, owing to the fact, perhaps, that it was instilled—that is the word, *instilled*—by jabbing me over the head with the book itself. There is something logical involved in this system, by which you will observe that the contents of the book are brought into direct connection with the brain-pan itself. It is thus that I never have been able to forget the date of the Battle of Hastings, 1066. It drew blood!

DETAIL ON TOWERS AT MAIN ENTRANCE.

But even if we choose to think that it is not unsuitable that the education of boys should consist primarily in forming in them the habit of remembering—and in view of the character and of the manner in which public examinations are now conducted, this form of education has, indeed, some excuse made for it—we must recognise that, when applied to the professional education of young men who anticipate practising as architects, the utterly disastrous results of directing the studies of these young men in such a way that they aspire to become proficient in the ideals of every age and country except their own, and to lay up in mind the tabulated experiences of other people rather than to grasp the ideals and needs of the present day, and to habituate themselves to cultivate their own ingenuity, observation and invention, cannot be exaggerated. I shall have more to say upon this subject shortly, but I wish now to deal a little more clearly with the examination. It has been brought forward by the votaries of registration that the proposed Bill means little more than the enforcement by compulsion of all who would call themselves architects to pass the examinations held by the Royal Institute of British Architects. I confess, generally, that I am not very much in sympathy with the Royal Institute. I hope any of you will take the opportunity of putting me right if I am in error; but I feel always that the Institute is not unjustly represented by the nickname of "Royal Institute of Five-per-centers." I do not say that the Institute is deserving of this twit in any exact or positive line of action it has adopted, but rather from what seems to me its lamentable neglect of what should be, to my thinking, the most pronounced and most salient characteristic of a body which esteems itself as representing under royal charter the interests of architecture in England. I think the Institute is associated much too closely with what I have already called "the paunch and frock coat of the profession," and that it has not identified itself with any subject whatever which has in view the furtherance of the vital and essential elements which make architecture a living national art rather than an opportunity for gentlemen to make handsome incomes with dignity and high repute of their fellow citizens. Upon whatever occasions, and in whatever circumstances, one approaches the Institute, one expects to find that the prevailing tone and the essential tendency of its actions are in the interests of five-per-centism or archæology; and one is never mistaken. I think that this quality of the Institute is exemplified by their system of examination. At the best the examination assumes to turn out young men decently educated, who are not likely to do anything which cannot be substantiated from a text-book, and are not likely to design anything the form of which cannot be traced in the traditional architecture of some country or other at some date of its history, and, in general, young men who are immensely gratified by realising that they are equipped fully to obtain a client and tear a five per cent. out of him. I am anxious not to be unfair, but I think this is no inexact description of the average output of the Institute.

THE MAIN DOME IN PROCESS OF CONSTRUCTION.

It is hardly necessary to point out that the examinations are entirely elementary in principle. It is true that it may not be possible to pass the examinations without trouble and time, but the character of the examinations is none the less elementary, though often in recondite and abstruse subjects. The processes of these examinations may be described as architecture by rote. The immediate product, taken as a whole, will be healthy young five-per-centers, who have subjugated the legitimate functions of their brains for a time, and have assumed formulæ, tables of facts, strings of dates, graduated weights of lead pipes, &c., and stores of similar useless fatuous things. They have acquired images and data of traditional forms of architecture all analysed and tabulated in readiness to be produced, drawn and articulated with the precision of Mr. Maskelyne's mechanical drawing girl, and the whole of which it is their salvation only to forget as soon as possible. Although it does not mitigate the fatuity of these examinations as an institution for qualifying architects, it is due to those who regulate them to say that it is difficult at all to conceive how they can be made other than elementary and impracticable. If it be considered, the various phases of architectural practice and its field of experience are so wide and varied, and the whole of so essentially a practical character, that it is clearly only possible to examine an incompetent man. The fact of a man's capabilities as an architect having been really and fully assessed in examination may be considered conclusive of his incompetency, for if a man has had the responsibility of conducting a certain class of architectural work, there is no one who can assume to examine him. In the field of his own experience the examinee can stultify his examiner, for no text-book can confute him; his examiner's field of experience is limited; and even if his examiner's field of experience should tally precisely with his own, and his conclusions yet be in antitheses, he cannot be convicted of error. It must stand merely as a difference of opinion.

There is no answer to his "I have done it" even were the text-books not notoriously at variance on subjects which would seem to be ascertainable facts. An admission of this portentous anomaly in the examination is made in the nervous distrust of the examining authorities, who arrange for a personal interview with the applicant before daring to "pluck" him. The examinee has written things in his papers which the examiners never heard of or which seem wrong—but it cannot be decided whether ignorance is on the side of the examiner or applicant until it is seen how the latter comports himself when challenged. In other words, the examiners (from the nature of the subject) cannot answer the questions they set except in an elementary manner, and it seems likely that a really admirable brazen liar could not be "plucked" by power of man. Here one finds a new lurking significance in the letters A.R.I.B.A. The examination as it now stands is easy and bland to the student, who, having induced atrophy of his thinking powers, has by the process of cramming acquired extracted handbook essences, and who generally knows his subjects as a child who sings in class "N'thumberlandnewcastle-on-th'tine" knows geography, but is harsh to the man who has knowledge and experience. The former, for instance, will give the recipe for putty by the reel, and repeat accurately in the words of his authority all "Rivington's" entirely inaccurate statements anent, for instance, the slaking of ground stone lime, although he may never have seen either, and he duly gains credit; while the latter, treating the matters insignificantly and from practical knowledge of them, will win to associateship, if at all, by cowing the examiner in personal interview.

Only the other day I was speaking of this matter with a friend of mine who does not altogether agree with the views I have just put forward; this may be partly explained by the fact that he is an "Ashpitel" prizeman. He admitted, however, that though it is many years since he won his success, and although he has since had wide and varied practice, he did not think he could without preparation pass the examination now, though he said he believed

THE BUNGALOW RESTAURANT, GLASGOW EXHIBITION.

that with a month's study he could do all and probably more than he had previously achieved in the way of earning marks. If we are to accept this as a statement of this gentleman's indebtedness to the examination—and I think it is probably a quite just and exact statement—it shows pretty clearly that the knowledge acquired in preparation for this examination is not the kind of knowledge which is applicable to a man in his practical work, or information of a kind which practical experience adds to or strengthens. Apart from this, as I have already pointed out, we have to take into consideration the highly derogatory influences which the process of storing data, facts and information generally in the mind has upon the processes of thought, power of imagination and selection, and upon that ingenuity and activity of resource which always mark and distinguish the capabilities of an architect.

I think that any general investigation of the condition of architecture in this country shows us clearly that it is our attitude towards tradition which more than anything else is stifling the impulses which tend to place architecture in the position of a great national art. We are hag-ridden by the traditions of past architectures. We find it very difficult to conceive a design except as represented in one or other traditional style, or, let me say, except as represented in the forms directly derived and exemplified in traditional styles of architecture. In Mr. W. Emerson's inaugural address as president of the Institute—and I refer to it as being the address of the president of the society which is taken to represent the best impulses of architectural practice—there is a passage in which he laments and bewails that undoubtedly the arcade gives the architect his only chance of making shop fronts constructively reasonable, and that at present huge facades of stone or terra-cotta and brick appear to be slung in air over a yawning abyss of plate glass. He adds that, of course, everyone knows that they rest on iron girders and columns, but a well-designed arcade would give a sense of safety and constructive propriety. I only call attention to this remark because it is on a par with many similar opinions which are frequently expressed. What is the grievance? Apparently Mr. Emerson, and people who think as he does, resent the necessities which compel architects to raise buildings over big shop windows in which there is plate glass; that is to say, that these gentlemen protest against and regret the insuperable difficulties of the adaptation of traditional styles under the conditions in which they have to work; to fill it in more fully, I take it that their objection is, "How on earth am I to take a stone lintel across an opening of 15ft., when I find that there has been no tradition of architecture in the history of the world which has ever in any degree provided forms or devices by which a span such as this one can be covered under the conditions which the needs of this case enforce?"

Well, we will grant that this is an exact statement. We will grant that architects, as needs have arisen, have stretched out their arches until they have become lintels, and pulled out their lintels, like sealing wax, until they were nothing; and we can appreciate that men of Mr. Emerson's nice discrimination and æsthetic sensitiveness would revolt from such outrages upon arches and lintel. Then, what is to be done? Apparently architecture as it would be rendered by architects of the greatest prominence and acquirements must cease; or else the public must leave off desiring shop windows with plate glass on the ground floor of lofty buildings.

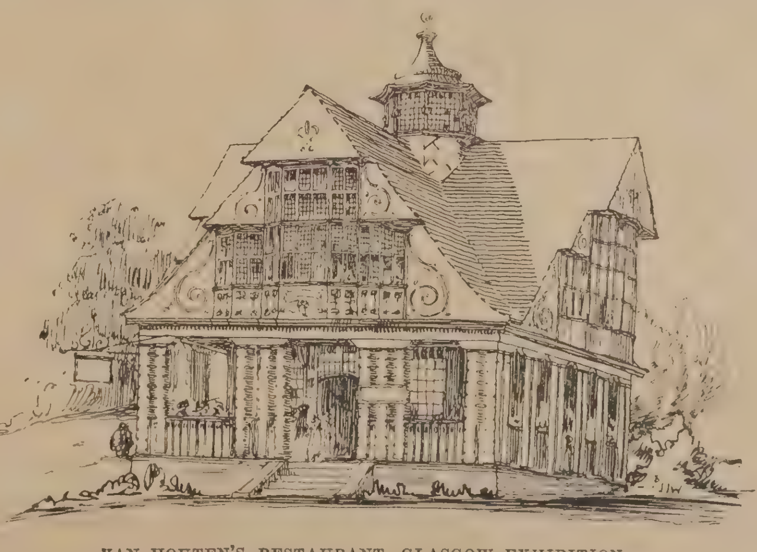
As far as I can make out, the matter is generally accepted as resolving itself into these two questions. As the second alternative is out of the question, we go on as we have been going on testing the elastic possibilities of arches and lintels, and training our eye and our mind until it discovers nothing unfitting in terra-cotta columns of a diameter which would be totally insufficient even if the material were the hardest granite and the other forms described by Mr. Emerson, and we generally shrug our shoulders and consider that we are making the best of a bad business.

Now, gentlemen, I wish to put it to you whether, so far from these unusual conditions and requirements with which our clients saddle us tending to restrict, deform and stultify the usages of architecture, they do not rather open up possibilities and give us opportunities which perhaps at no other epoch in the history of the world have before arisen. I ask you to consider what was the predicament of the early Doric builders when they first essayed to build with stone from the quarry, or what that of the Greek architects who sought to raise their traditional styles in Rome, where the materials of their craft were largely wanting; or what that of the early Romanesque builders in France and elsewhere who had to devise structures of freestone which theretofore had been rendered in large and hard stones of deep red. All three of these peoples at these three different epochs have formed a landmark in the history of architecture, and raised a monument to human ingenuity and truth of emotion which while the world lasts will be regarded as among its greatest wonders. So, again, may we not recall that almost greater wonder, the evolution of the Renaissance styles, which were not the result of any necessity whatever, but arose from some subtle mental reaction against forms and traditions grown too familiar.

I put it to you, gentlemen, that the predicament in which the Greeks and the Romans and the Normans found themselves, and which they faced with such triumphant results, were every whit as insuperable as those which Mr. Emerson calls attention to in his address. I think I may say that each of these peoples answered the questions put to them not by straining their traditions to fit the needs but by continually admitting these needs and eulogising them. There is no doubt that some such process creative of changes and modifications which took place at each of the periods which I have alluded to is now taking place with us; but we of the nineteenth century, who like to call ourselves the heirs of the ages, have the privilege of other people's experience and the wide view of past history, accessible to us and familiar to us all, to guide us and stimulate us in the right direction, and assure us that the direction which we take and the views we are adopting are those which will lead us to some such triumph as has waited upon our predecessors in the centuries past.

Instead, then, of regretting the need for structural ironwork, and attempting to hide and disguise it, we must not only avow it, but seek to emphasise it and decorate it. If we think that a rolled steel joist is an ugly thing in itself, that must be entirely and solely a matter of prejudice, because the quality of steel and of iron is a thing which is extremely beautiful, and, as compared with other materials, unique and wonderful. It is true that when we use a rolled steel joist where we would expect a stone lintel, it is offensive to us because our eye, or rather our mind, is prejudiced by being long accustomed to see its place occupied by a material which we have learned to admire and eulogise as possessing quite other qualities.

I think myself that a great deal might be done in the candid use of cast-iron beams, which from their nature and texture partake more exactly of the quality of the true lintel as we have learnt to regard it than does a rolled steel joist or a built-up girder. It is obvious, however, that if such material is to be incorporated in the design of a building, there must not be in the design of that building features which long habitude of convention and taste and prejudices have associated with arches or with stone lintels. But I do not wish to take exact instances or to analyse the practical application of the theory which I am trying to express—it is a very interesting speculation, but this is not the place for it. What I wish to insist upon is that if we are to be "live architects," to borrow an Americanism, we must place ourselves in close sympathy with the ideals and the needs of our own day.



VAN HOUTEN'S RESTAURANT, GLASGOW EXHIBITION.

There are many aspects of the practice of architecture which should make our own particular epoch particularly sanguine to the anticipation of architects, but, on the other hand, we have as a body serious limitations and very grave deficiencies in our attitude towards our art and our attitude towards the time. I think, perhaps, the most salient of these is the lack of robustness in our view of things, and our attitude towards life; and a certain æsthetic self-indulgence—shall I say?—in our architectural habit. There is, as we are all conscious and as we all experience, a very deep attractiveness in the romance that attaches to what is old and to what is associated with the life of our ancestors or the past history of the nation. It is a sentiment which simple people of essentially philistine and average intelligence can understand and appreciate. It is a sentiment which stimulates the imagination, and it is very easy to achieve—shall I say?—the poetic afflatus when the mind is environed with these associations. But this, I feel very strongly and wish to insist with a good deal of emphasis, is not the attitude towards art or architecture or poetry which ever does or ever will constitute an epoch which posterity will look back upon as forming a landmark or producing a school of thought or artistic achievement. The schools of art that have found a place in history have been schools that were intimately in touch with the life of their day and the aspirations of their surroundings. The men whose work has lived and has been proved to be intrinsically sound, true and good have always been the men who were an integral part of the system and surroundings in which they lived. I do not think I need insist further upon this point; it may be amplified and enlarged upon almost without limit. We do not really try hard enough; we have no right to rest on our oars and enjoy the dreamy images created in the romantic atmosphere which frames the past. If any architecture worthy the name is to be built at all, it will be an architecture that expresses the needs, ideals and conditions in which we live. Nothing will be achieved by the work of any cult. We may all of us see this in the vapid folly and crudeness and unreality of the work of the revivalists. There is a great deal in which the impulses of the revivalists are still seen. We note the inability of the nation—of architects—to express even its religion. We are beginning to try to do so a little, but until lately no one seems to have tried to build a church except such a one as expressed the mystic surroundings of centuries passed, when devotees with red-hot pincers tore the toe-nails out of other devotees who happened to be fewer in number or who had not their pincers with them. I think, however, that the baldness of thought and feeling that mark church architecture is more due to the prejudices which attach to the modern devotee than to the fault of architects. People think that there is no more reason why the form and the sentiment expressed in the forms of the architecture of their churches should be changed than that the prayer book should be reprinted. The curious thing is—though, indeed, I think it is only what would be expected—that the class of architecture which will be regarded by posterity as having the most sincere distinctive mark, the essentially characteristic mark as attaching to this epoch in architectural history, is by us almost disregarded and by the majority of us, I believe, tabooed as being unworthy of the highest traditions of the architect—I allude to public-houses and restaurants. I see in these, as put up in our large provincial towns and in London, a style of architecture which is generally distinct from anything traditional, which perfectly expresses the sentiments and the needs of its existence (which I take to be to satisfy the æsthetic want of a muzzy or drunken man); and I take it that this style has been evolved, and a tradition has gradually grown and attached itself to the idea of what a public-house should be, without any thought being expended on the subject except such as would enable an architect to satisfy his client; and that such architectural education or culture as belongs to the profession of architecture has had no bearing or very little bearing upon the motive, nor has it regulated the forms and decorations which mark these buildings. If we realise this, we may regret that some serious attention has not been given to this class of building. The growth of restaurants and hotels during the last ten years, chiefly in London, has been phenomenal, yet I may say that the profession of architecture has had little or no voice, and has not exerted itself or achieved any substantial uplifting or chastening of the crude wants of an inebriated public. For my own part I think that the direction which offers the best opportunities to the architects who are going to raise the characteristic twentieth-century architecture, which I insist will be in many ways a revolution of previous principles, is that afforded by such things as pumping stations, waterworks, electric-lighting stations, gasworks, and so forth.

I think the man who had the opportunity of designing or building soap works or a bone-manure factory would have such an opportunity as few architects in the world's history have surpassed. We still have prejudices that such things as soap-works, waterworks, gasworks are not things that it is possible to express or idealise in architecture; but to that I, for one, am in very strong opposition.

These factories and works are the centres of human history, and are the hub round which the life of the people and the life of the nation is centred. If the life surrounding these places is squalid, unhealthy and destitute of the wholesome recreation and relaxation which alone makes life a graceful or worthy thing, this is not due in itself to the nature of the employment, nor perhaps rather to the fact that these industries are all of so recent a date that the race is not yet accustomed to the new conditions in which it finds itself. It is the prerogative of architects to invent forms which shall eulogise such needs and employments of the race.

I think that most of us, though we could rise to the possibilities offered in the opportunity of designing a cloister, and would have no difficulty in calling up that essential element of enthusiasm and imaginative activity from which alone an appropriate design can emanate; and though we should have no difficulty in acquitting ourselves to our satisfaction in the matter of this thing, which has been for some 200 years dissociated with life in England, and which is suggestive of nothing more than what we hold to be the gloomy horrors of ignorance—we should few of us succeed, even if we had the intrepidity to try, in adequately or even in any degree expressing the idealisation of soap works in the architecture of the building.

In giving this particular instance there is perhaps the danger of reducing my contention to absurdity, but I am perfectly sincere and earnest in what I say, and if you will admit that the true mission of architecture is rather to idealise and eulogise such wholesome and dignified institutions of our age as pumping stations or electric-light stations, you will see, I think, that it ought to be ambitious of the power to make even soap-works or bone-manure factories, whose existence is coincident with the nation's prosperity, and to which a large part of the population have to look for their means of sustenance, actively expressive of the undoubted dignity of their purpose.

As I have already said, I cannot, and do not, believe that the great epochs of architecture were created by men who worked in the atmosphere of retrospection in which we work, or who drew the enthusiasm which inspired their work from the romance which attaches to the associations of the past.

We are always tasting our own dishes; we are always congratulating ourselves; we all are tremendously conscious—know we are Artists with a big A. This I firmly believe to be annihilation to all effective work; and by effective I mean sterling work. This notorious quality which belongs to us among the spheres of activity at this present day has drawn from Mr. H. Wilson the witty saying that there can be no art where there are artists.

I take it that the Dutch, when they decorated and shaped their milking cans and dairy and kitchen utensils, did so from a feeling of instinctive dignity and fitness which they desired to see expressed in their surroundings rather than from any self-congratulatory idea that they were artists, or with any idea that these things were fit to be set about and looked upon solely for the intrinsic beauty of their outline and decoration. I think the lack of robustness in our ideals, and lack of aptitude to cope with the exigencies and demands of the times in which we live, is in itself, if it were not counteracted by other aspects, a distinctly decadent impulse, such as would mark a decaying and decadent race. It is quite fair to say of the ruck of our profession that they are standing on each other's feet. They do not move to fresh enterprises of their own, but hang each on to the lapel of his fellow's coat—that Jones did so-and-so is a good reason for Brown to do likewise. The illustrations in the professional journals are a bugbear. I have myself worked in an office where some forty or 400—I forget which—volumes of the "Building News" formed what I may describe as the working capital of the office. It is terrible to think of the number of buildings which owe their genesis to the litter of perspective views which fall on our heads once a week from the regions of Fleet Street and Covent Garden. Is any prospect more truly hopeless to the existence of architecture at all than that such a custom should obtain among us? There is a metaphor which is applied to men who exist by reproducing themselves, namely, that they live by sucking their own paws; but I think that we architects are deserving of a more unsavoury comparison, for the bulk of us may be said to exist not indeed by sucking our paws, but by sucking each other's paws.

Gentlemen, I think that so long as we are content to shelve the responsibility which undoubtedly attaches to our profession in this matter, that all hope of resuscitating the true spirit of architecture is at an end, and I think that nothing is more hopeful or more suspicious to contemplate than these insuperable difficulties of plate glass and shop windows which the President of the Institute of British Architects laments; and I think that nothing holds forward a better hope of the foundation of a new and a true architectural epoch in this present century than the opportunity which may be offered to architects to supply new needs with new materials, whose æsthetic possibilities hitherto throughout the history of the world no architect has ever had to deal with. I have dwelt so long upon this part of my subject, because it seems to me that the examinations of the Institute of British Architects—and I think any other examination as distinct from a course of study which it is easy to imagine—would effect that all would-be architects in the years of their studentships would be qualifying and training themselves in precisely this same habit of thought and method of work which I have been depreciating. The present conventions would be formulated by State interference. Registered architects implies registered architecture of this hopeless order. I do not think that any examination can be so designed and carried out as not to have essentially the same faults, and not to lead to essentially the same bad results as those which are undoubtedly effected by the examinations of the British Institute.

It is not merely that the conditions of the examinations—if, indeed, they do not entirely preclude the mental processes of design—require an examinee to draw something he remembers, and give preference to a design in which tradition forms appear, but that the whole tendency of the examination is to direct prejudices of architects into those proven paths of wrongness which were idealised early in this century. We, the new blood, the vital element of architectural progress, have long satisfied ourselves of the essential ignorance involved in the motives which directed the enthusiasm of the revivalists. They thought that by attempting to repeat an inimitable thing they were perpetuating the beautiful. These repetitions, irremediably ugly and stupid, writ over with a conscious vain effort of design, smelling of india-rubber, of 5 per cent., of the contract system, of provincial p.c. amounts for carving—these imitations, spread about over the country, have almost made the inimitable incentives to the craze repulsive to us. Is it not within our common experience to enter one of these inimitable mediæval buildings and gaze upon it in mental weariness? On all sides its parts recall parallel or divers treatments, and provoke comparisons among hosts of modern buildings cheap, uncandid, of repugnant associations, spring visited by the Architectural Association, or published in the ruck of published perspective views. By them our critical faculties are become jaded and enervated, our taste by constant analysis debauched, we are *blasé* and insensible. Ours has been the loss of the man who makes scented cotton roses for a living, when he goes into the summer garden; and we have deserved it. If we all wear sham jewellery the essential beauty of true gems will soon be placed beyond our powers of appreciation; and it is further true that admiration of the kind that, on its own initative, sets about to make an imitation of the thing admired is of a gross calibre and points to the savage's insensibility of perceptions. What do we read in the destiny of a nation which is at once so oblivious to the mystery, pathos and almost sanctity attaching to the examples of the conventions of art of past ages as to desire to associate them with their drinking and money-getting, and at the same time has not the vitality to idealise its own life and aspirations? We have frank indications that this order is passing, and that it is to be changed by this generation. The principle of eclecticism has long been established, and is now ideal with us which tends to the error of being transcendental. The modern building which we now hold distinguished is that which holds no reflections in its elevation, and returns no echoes. In their susceptible days our fathers only considered a building to pass muster when it showed a polite and scholarly relationship to precise traditions in its parts and proportions. And it is our fathers who now sit in power at 9, Conduit Street, and frame proposals for registration. Is not this how it comes about that the Royal Institute of British—I was going to say Four-per-centers—Architects, &c., &c., in its scheme of examination enforces a principle of education which is opposed to the redeeming spirit of eclecticism. Thus it requires: "Give the dates of ——," &c., &c., &c.; "draw to half-inch scale an example of ——," &c., &c., &c.; "state the proportions of ——," &c., &c., &c.

I now come to what may be called the somewhat transcendent aspect of my subject. It has been urged by those who advocate the Institute examination that the examination offers a young man an opportunity of obtaining employment which will be an advantage to him when he first takes his place in the practice of the profession of architecture, but I do not think it is necessary to make any remark in retort upon such a contention. It is undoubtedly true, but is of course entirely beside the mark. If the examination is to be employed at all, it must be on the ground that it benefits the profession of architecture or that it magnifies the status of architecture.

It has been, however, urged that there is no sort of reason why a man should not avail himself of all possible advantages, and that, after all, if a man should choose the course of educating himself on the lines indicated by the examination, and so qualify himself, he only acts in accordance with sound common-sense. No doubt, people who put forward such a contention as that think they have made a strong point. I can only say, for my part, that I think it entirely discredits the examination, and entirely discredits the motives and ambitions of those who upon such grounds advance the claims of examination and of registration; for, gentlemen, what is common-sense?

I think, if we consider it, we shall realise that the quality of common-sense when we get beyond the sphere of activity of the small retail tradesman, let us say—that the quality of common-sense is one which is almost entirely absent from among the characteristics of men who have done things that the world was glad to remember and think of after they were gone. If we imagine Isaac Newton a man of "sound common sense," we must imagine him eating the apple when it fell. Who, gentlemen, but a man devoid of all common-sense when the kettle was boiling would ponder upon the reasons of its boiling instead of enjoying himself, shaving himself and moving upon his business? Yet it was by such a man that the world was introduced to the potentiality of steam. I may mention to you the name of a man to whom all of us, whatever our views and however we may regard the views of this great man, yet owe a great deal, who had no suggestion or taint whatever of common-sense—I refer to John Ruskin. The very essence of common-sense is the prudence and foresight that avoids risk, the foresight that enables a thing to be done as easily and as profitably as may be. On the other hand, the very essence of all original effort and of all art worthy the name, and, indeed, of all real work, is to make sacrifices and to take risks. I find it very hard to recall an instance of any man whose work we remember with gratitude as having helped us and taught us whose life is not very largely a continual example of sacrifice great or small; and what is the history of the individual is the history of the cult or school to which he belongs. I think it is this very element of sacrifice, of giving without return, without speculation for return which really does constitute what is great, inspiring and ennobling in all art. The work that is done for money or that is done the easy way, though we may not recognise it at the time when our view is distorted by convention and the reactions of fashion in which we live, will to posterity always bear the clear mark and indication of having been done for money or having been done easily and without pains. It is this element, I take it, that Ruskin continually insists upon in his writings under the somewhat unfortunate term of "worship."

I think we can hardly turn to a conspicuous name in creative thought or in the domain of art but we find just this same self-immolation. I recall that Romney sent his wife away from him because he found that her proximity interfered with his ability to clearly conceive and render his pictures. Those of us who have read the Vailima Letters may recall the extraordinary self-denials which Stevenson enforced upon himself in order that his work might be rendered at that high nervous pitch and tension which, indeed, eventually killed him.

There is the same instance in the splendid devotion of another writer, Mr. George Meredith, who has stuck to his own ideals and persistently and unwaveringly held to his own convictions in the face of years of misunderstanding and misinterpretation and the abuse of critics. It may not be generally known among you, gentlemen, "Richard Feverel" was published in the same year as "Adam Bede."

I do not think it is in the least necessary to amplify this point. The thing which never vanishes in the work of a man or the work of a school, cult or profession is the motive of it. If work is to be done for 5 per cent. or if it is going to be done in order to attract clients, the building will bear written on its face for ever: "This was done for 5 per cent.; this was done to please the crowd."

At the same time, as I have already said, it cannot for one moment be said that a man is not perfectly justified in declining to make these sacrifices, and in electing to live a life of more complacency and one less nervously enervating. But even then his motives should be the highest motives if he is to take his place in the rendering of such subtle and complex matters as the architect is called upon to contemplate; and though we have small chance of giving expression to our highest enthusiasm, or of seeing our most disinterested ambitions realised, it is the very essence and life of the practice of architecture that such ambitions and ideals should exist and be recognised, and where should such ambitions and enthusiasms exists if they are not to be found among young men, if they are not to be inculcated among those who are preparing themselves to take a part in the profession? And how hopeless must any project of architectural improvement appear if a system is adopted which involves conditions of education, which, I think, without any unfairness or any exaggeration, may be said to depreciate enterprice and high ambition, which tends to depreciate all instinct for abstract reflection, or, indeed, of thought or reflectiveness of any kind, and which is clearly formulated in the interests of the profession and five-per-centism rather than in the interests of the advancement of architecture from its present submerged state to a national living art. And of those gentlemen who are willing to make sacrifices in the cause of their ideals and to deny themselves the luxury of a professional paunch, and to whom the architecture they are responsible for is the best and highest good, what is their reward?

I have nothing better to say to this than to ask you to read the little parable by John Ruskin (in his "Queen of the Air"). It has been christened "The Fly and the Watch Dog."

Correspondence.

Examination Questions in Building Construction.

To the Editor of THE BUILDERS' JOURNAL.

GLOUCESTER.

SIR,—Most persons are, at last, becoming aware of the fact that examinations are not fair tests of knowledge, and I quite agree with the remarks made by "A Student" on p. 309 of your last issue. Personally, I am quite disgusted with the building examinations. Anyone who knows a little about building construction, if he takes the trouble to examine the papers for the last five years, will notice that the questions are annually becoming more difficult and less easy to understand. I think that this subject is very badly taught in schools. For instance, I have more than once known a student set to "do a door," and he puts plan, elevation and section in almost any position upon his paper, not having the least idea that there is any connection between the three; and this after two or three months' teaching! The more students that are pushed through the examination the better for the school, and the Government grant.—Yours truly,

ANOTHER STUDENT.

To the Editor of THE BUILDERS' JOURNAL.

SIR —I must emphatically endorse the remarks of "Student" in your last issue with reference to the questions in the recent examination of the Science and Art Department in building construction.

For instance, in the Honours examination, Division III., a figured diagram is given of a shop front with the height from floor to floor figured as 12in. It may be intended as 12ft., but how is the candidate to know this is not a catch question intended to test his powers of observation. Two answers depended on this diagram.

In the same examination, Division II. (dealing with strength of materials), there are only three questions, and a failure to answer one of them correctly is fatal to the candidate's success. All reference to tables, &c., is strictly forbidden, yet the first question, which relates to the strength and stability of a factory chimney, cannot be answered without reference to a table which gives the value of a hollow rectangle. Rivington, Part IV., works out an example of the stability of a chimney, but refers the student to a table (Appendix XIX.) at the end of the volume for the value of a hollow rectangle. Then, again, this question relates to a factory chimney, whereas the syllabus distinctly states "in ordinary walls . . . he must be able to ascertain the conditions necessary to stability, &c." A factory chimney is scarcely an "ordinary wall," but this is perhaps a small objection, as the principles are the same. In the same division, second question, the forces acting on a roof are shown at varying angles, and the way to resolve these normal to the roof surface is by multiplying them by the cosine of the included angle, which cannot be done without reference to a table of natural or logarithmic sines, &c. In the third question, the weight per foot of a rolled joist of given dimension is asked, which depends on a formula rarely used in practice, as manufacturers' lists are depended on for the weight of various sections. This is not hinted at in the syllabus, which says, "he must be able to . . . determine the safe dimensions of iron or wooden beams subjected to dead loads."

Thus in Division II., out of three questions, two could not have been answered without reference to tables, and the third depended on a rarely used formula about the weight of iron girders, when only the "safe dimensions" are asked for in the syllabus, and these do not depend on the weight per foot. The examiners were also very strict in forbidding the students to take away the printed questions, although this, I understood, was allowed in previous years. Was this to prevent criticism?

The time allowed is the same (four hours) for Elementary Advanced and Honours divisions, which seems a mistake, as it is almost impossible to do full justice to a paper which entails a large amount of detail drawing and sketches in the same time allowed for an elementary examination.—Yours truly,

ANOTHER STUDENT.

HEREFORD CATHEDRAL FROM BELOW THE BRIDGE.

Views & Reviews.

HEREFORD CATHEDRAL.

THE interest of this little book depends not so much on its letterpress, as for the several delightful illustrations by Mr. Hedley Fitton, who possesses the ability to draw architecture in a "sketchy" manner while being truthful to the construction. This combination in a draughtsman is rarely found in the same degree; for either the technique of the drawing is excellent and the architecture depicted without knowledge, or the architectural construction shown correctly, but in a harsh and inartistic manner. It is the mark of excellence when the draughtsman combines these two qualities. Though Mr. Fitton's sketches form the main attraction of the book, still the Dean tells the history of this old cathedral in a very readable manner. The event which first brought the building to the general notice of Christendom was the murder of Ethelbert (king of the East Angles), an event variously related and embellished and one which resulted in Offa (king of Mercia) raising a costly church over the grave of his rival king; the church became that of St. Mary and St. Ethelbert. After the death of Offa and of his son, Mildred built "an admirable stone church" at Hereford, but at the end of 200 years it had so fallen into decay that Ethelstan, bishop in 1012, appears to have entirely rebuilt it; about forty years later, however, it was pillaged and destroyed by fire, together with a considerable part of the city, so that scarcely any remains of it are traceable. Soon afterwards Robert de Lozing, or Lorraine, commenced a new cathedral, which was completed by his successor, Bishop Reynhelm, and it is this structure which forms the bulk of the present edifice. The outer porch of the north entrance was erected by Bishop Booth in the sixteenth century, and "may be said to be the last work of the grand old bishop-builders, the work after that being restoration, or in some cases deformation, as was the case when the west tower fell in 1786, crushing in its fall much of the west end; the rebuilding of it was entrusted to James Wyatt, who substituted his own feeble Gothic for the fine Norman facade, triforium and clerestory, and shortened the nave by 16ft. It was well said by a writer soon after the rebuilding: 'It was only in ruins when the tower fell; it was not ruined until James Wyatt had done with it.'"

Hereford Cathedral contains examples of all the varieties of work from the Norman to the Gothic, and is therefore a singularly interesting building. Each successive builder worked in the style of his century, and seemed to be actuated by no desire for uniformity throughout the structure. "The student will find here the choicest specimens of both earlier and later architectural skill. He may see by what an easy yet perceptible gradation each style advances on the preceding. For instance, in the south transept may be seen some striking examples of early Norman of the eleventh century (possibly, although this is not certain, remains of Bishop Ethelstan's church, which was destroyed in 1055); the tall arches of wall arcade (similar to those in Lombardy); the balustraded triforium (like the eleventh-century transepts of St. Albans, Chester and Pershore)." The north transept is a fine example of Middle Geometrical of the thirteenth century, whilst Perpendicular work may be studied in the large windows of the south transept, and the Audley and Stanbury chapels. The choir has heavy masses of wall, like St. Albans and Chichester, supporting finely-carved arches and the magnificent triforium, the work of Robert de Lorraine. Transitional work may be seen in the retro-choir and what originally constituted the ambulatory; whilst the lancet of the thirteenth century is represented by the Lady Chapel. The cathedral is also rich in monumental effigies. At this time of the year it forms a delightful subject for a visit; and to those intending to take such a holiday, we would recommend this little book, written in an interesting manner and illustrated by a skilful draughtsman.

HEREFORD CATHEDRAL FROM THE WEST.

"Hereford Cathedral." By the Very Rev. Dean Leigh. Isbister & Co., Ltd., 15 and 16, Tavistock Street, Covent Garden, W.C.; price 1s. nett.

Builders' Notes.

Thomas Darby, master builder, of 2, Brighton Street, Nottingham, died recently.

Mr. Alexander Stephen, master plasterer, of Cameron Street, Stonehaven, died recently at the age of seventy-six years.

Mr. James Marsh, builder and contractor, of St. Annes, died recently. Deceased erected large blocks of property at Leigh, Chorley, and for the last twelve years at Horwich, where he was a member of the district council. His last undertaking was for 500 houses at Vickerstown, Barrow.

Sunday Building Operations.—When the report of the West Ham Town Council Works Committee was recently under consideration, Councillor Terrett called attention to the fact that in South West Ham building operations were carried on on Sundays. It was their duty to see that the plans were properly carried out. If builders were hard at work on Sundays, when the inspectors were having their day of rest, that was the day when their plans would be evaded, and when work would be done which was not in accordance with the plans. Of course they had no power to say these men should not build on Sunday, but the inspectors have power to go on Monday morning, and if they saw work done since the Saturday which was not right, they could have that work pulled down. He did not mind building going on on Sunday, but it ought to be inspected.

British Fire Prevention Committee.—The formal opening of the Committee's new fire-testing station at Westbourne Lodge, Bayswater, took place on Wednesday afternoon last, Mr. Edwin O. Sachs himself being present. Like their former premises at the side of the Regent's Canal, an old house has been utilised for the purposes of the Committee, in the garden of which two single and two double testing huts have been built; formerly they had only four single huts. During the afternoon tests were conducted with a ventilated floor, a suspended ceiling under wood joists and a partition, all by Bank's Fireproof Construction Syndicate, Ltd. The results of these tests will be published in our columns later, when the official report is issued. A large number of photographs of various materials and fittings subjected to fire tests were exhibited in the Lodge, as well as a model of the huts and gas-generating apparatus. This model was made by Mr. John B. Thorp, and is for an exhibition to be held at Berlin.

London County Council.—At last week's meeting the Technical Education Board brought up a report recommending the purchase for £45,000 of a site at the corner of Southampton Row and Orange Street, Bloomsbury, for the erection of a new building for the Central School of Arts and Crafts, now housed in Regent Street (see p. 301 of our last issue). The recommendation was adopted without discussion.—The Inebriates Acts Committee recommended that £17,660 should be expended on the provision of additional buildings at Farnfield to accommodate ninety inmates. This was agreed to.—On the recommendation of the Public Health Committee the by-laws under the Public Health Act, 1891, were amended so as to provide for the collection of house refuse in London not less than twice a week.—The Highways Committee recommended that tenders should be invited for the reconstruction, for electrical traction, of those portions of the London County Council tramways between (a) the junction of Kennington Road with Westminster Bridge Road and St. George's Circus; (b) the Elephant and Castle, along New and Old Kent Roads, New Cross Road, and Greenwich Road, to the terminus at Trafalgar Road, Greenwich; and (c) the Elephant and Castle, *via* Newington Causeway, to St. George's Church, Borough, and thence *via* Dover Street to the junction of New and Old Kent Roads. This was approved.—The Council have adjourned for the Whitsuntide recess until Tuesday, June 18th.

A Bronze Statue of Queen Victoria is being erected in the Dunn Square, Paisley, and the pedestal is now finished. The sculptor is Mr. F. J. Williamson, London.

RECONSTRUCTION OF GLASGOW ROYAL INFIRMARY.

The Executive Committee defend their Action.

OUR readers will doubtless recollect that some months ago considerable attention was drawn to the action of the Executive Committee respecting the plans for the reconstruction of the Glasgow Royal Infirmary, the Committee having overridden the selection made by their professional assessor, Dr. Rowand Anderson (see our issues for January 16th, January 30th and February 6th last). The Committee held a meeting recently, when a letter was read from the infirmary managers, who considered that the time had come for a definite policy to be adopted, and cited the following conclusions: (1) That an entire new hospital is an admitted necessity; (2) that the buildings on the north side, estimated to cost about £77,000, should be erected first; (3) that the money required for the entire new hospital, estimated at about £170,000, in addition to the £82,000 already in hand, should be subscribed before anything more is done; (4) that Lord Provost Chisholm, as head of the municipality, should be invited to initiate and guide the enterprise for the obtaining of subscriptions; (5) that the sum of £82,000 above referred to should be held *in retentis* to pay the cost of the front or south block when it comes to be erected; (6) that the new hospital, and not a section of it, should be regarded as alone worthy of the city of Glasgow, and as a fitting memorial to the sixty-three years' illustrious reign of the Queen.

The Committee next proceeded to consider the statement for the public formulated by their special sub-committee, and unanimously approved and adopted it. In the course of this statement it is said:—

The Site.

In regard to the site, the managers and the majority of the medical staff are agreed as to its perfect suitability. Dr. Russell, late medical officer of health for the city, has pronounced decidedly in its favour. It is situated in the very heart of a vast industrial population. It has been the universal experience of great towns that their large hospitals must be in the centres of the populations. It is so in London, with all its great hospitals, almost all of which are in crowded localities, the only exception being St. Thomas's, which was so fortunate as to secure a site on the river bank. St. Bartholomew's is at Smithfield, closely surrounded by narrow crowded streets; Guy's is in the congested district near Tooley Street; the London Hospital, the largest in the metropolis, is in Whitechapel; the Middlesex is in one of the most densely-built parts of London; King's College is everywhere surrounded by tall houses, and is approached only by narrow lanes; and University College Hospital, now being rebuilt, has four streets of houses for its boundaries.

In Manchester the case is still more pointed. There the Royal Infirmary is in the heart of the city, surrounded by business buildings, and the site is very valuable. It also requires to be reconstructed, and after long and anxious discussion, a strong party having favoured removal, it has been resolved to rebuild the entire infirmary upon its present site, which is not only more valuable but less desirable otherwise than ours.

The present site of the Glasgow Royal Infirmary is far superior to that of the Manchester Infirmary and to any of those in London that have been mentioned, with the exception alone of St. Thomas's. On one of its four sides it has the large and open Infirmary Square, on another it has the Necropolis, on a third, under the plan adopted, there will be a distance from the greater number of its windows of 250ft. to the buildings on the opposite side of Castle Street, and these great open areas are necessarily permanent and must remain to the infirmary in all time coming. In short, there is no other site in the city, or its immediate neighbourhood, that, in so far as open space and free ventilation are concerned, can at all compare with the position of the present institution for the erection of a great city infirmary.

Number of Beds.

Another question that has been discussed is the number of beds that should be provided in a new hospital on the present site, and it has been urged that in the future fewer beds than at present should be provided; that the site is much too small to permit of anything like the present number of 600 beds. It is true that in many of the wards of the present building the cubic space per bed is greatly insufficient, but this in no way disposes of the question. The plan adopted by the Executive Committee provides a cubic space for every one of the 660 beds as ample as the most advanced hospital reformer ever alleged to be necessary, and in every ward there is the fullest through-and-through ventilation from windows placed along the walls from end to end of the wards, in addition to whatever system of artificial ventilation may be adopted.

St. Bartholomew's Hospital has 600 beds, Guy's Hospital has 600 beds, the London Hospital has over 800 beds. All of these hospitals are on sites smaller than that of the Glasgow Royal Infirmary. It is true that this provision of ample bed space in our hospital is only to be obtained by carrying the buildings to a height of six storeys, but with the adequate provison of lifts this great height, so far from being a disadvantage, will be a decided benefit, and it will probably be found that the members of the professional staff of the infirmary will compete with each other for the upper floors.

Further, in the plan adopted by the Executive Committee the buildings are so arranged that only the minimum of shadow will be cast by any one block on any other, and this is one of the merits of the plan.

An Explanation regarding the Plans.

In regards to the plans this must be said: The Executive Committee and the managers bestowed on the subject lengthened and painstaking consideration. Authorities on hospital construction were consulted, visits were paid to the best hospitals in Great Britain and America, and the views of the staff of the infirmary as to the general conditions and requirements of the institution were carefully ascertained. As a result of this seven sketch plans were, under direction of the managers, prepared by Mr. George Hill, comprehending the provisions specified by the staff, and after due consideration agreed to by the managers as necessary for an infirmary which was desired to be abreast of the foremost institutions of the kind. Of these sketch plans, two which were specially selected by the managers were submitted to ten selected architects, but were distinctly stated to be "suggestive and illustrative only," not binding.

To assist the Executive Committee in deciding on the competing plans, Dr. Rowand Anderson was appointed as their assessor, his function being, as he himself frankly acknowledged, to guide and advise, not to select. When the final selection was made the Executive Committee fixed on a plan which the assessor reported as being one of two which most closely conformed to the sketch plans. The other of these two plans the assessor had placed first of all, but he had not included in his short leet that fixed on by the Executive Committee. Further interviews with the assessors satisfied the Executive Committee that its exclusion arose from no failure on the part of the selected plan in regard to vital or essential particulars, but chiefly from a difference of opinion in regard to the style of architecture and the general elevation—matters on which the Executive Committee ventured to think they were quite entitled to follow their own opinion, and the minority cordially acquiesced in the selection of the majority.

Internal Arrangements.

As regards internal arrangements, the plan selected by the Executive Committee is to be preferred for the following reasons: Firstly, that it provides on the main floor through-corridor communication from end to end of the building without passing through any of the wards. Secondly, on account of the superior lighting of the wards, by which every bed shall have share of a window for light and ventilation. Thirdly, that the venereal ward shall be isolated from all other wards. Fourthly, that small wards or side rooms are conveniently situated so that they can be entered without passing through the main wards. Fifthly, it gives a promenade on the roof for convalescent patients. Like most other plans of similar magnitude the internal arrangements of this plan are in some respects no doubt open to modification and improvement, and every care will be taken by those responsible for the work to ensure that all the arrangements shall be as perfect as possible.

Dwarfing the Cathedral.

It has been alleged that the buildings being so lofty will dwarf the cathedral. The buildings must be lofty if the hospital requirements of the public are to be adequately met, and the Executive Committee believe that they have shown discretion in approving the architectural style of the adopted plan. It is distinctively Scottish—the national art of the fifteenth and sixteenth centuries, of which we have examples in Heriot's Hospital, Holyrood, Linlithgow and Falkland palaces, and in our own old College lately in the High Street.

It is, therefore, not only appropriate to the historical associations of the site upon which stood the castellated Bishop's palace, but permitting, as it does, a limited use of Gothic forms as in Heriot's Hospital, Edinburgh, it is more in harmony with the cathedral itself than any classic or modern style. It was not, however, this consideration but the superiority of the plans which chiefly influenced the judgment of the Executive Committee. A careful consideration of the circumstances seems to suggest that the proper course out of the difficulty which has arisen is to face the entire reconstruction. It is undoubtedly more than the original idea with which the scheme was started, but it is not more than the necessities of the infirmary require; it is not more than the reputation of the city for public spirit and for determination to have all its institutions fully abreast of the times demands; and it is not more, when a good case is put before them, than the liberality of the citizens can overtake. The reconstruction of the entire infirmary is estimated to cost at least £250,000, so that a further sum of about £170,000 is required. It is a citizens' scheme, and must be treated as such. It must be fairly put before the citizens, and they may be safely left to see it carried through.

Law Cases.

Sueing the Commissioners of Works.—The case of *Graham & Sons* v. *The Commissioners of Works and Public Buildings* was heard in the King's Bench Division of the High Court of Justice on Wednesday last. It was an action brought to recover damages for breach of contract and for wrongful conversion of builders' plant. The plaintiffs, who were builders and contractors, in September, 1899, entered into a contract with the Commissioners of Works and Public Buildings to erect a post-office at Stalybridge, in Lancashire.—The Court gave judgment for the plaintiffs. Mr. Justice Ridley said that the matter depended upon the general principle that an officer of the Crown was not liable to be sued in respect of a contract made by him as agent of the Crown, and the question was whether the Commissioners of Works in this case were acting as agents of the Crown or not. There were several decisions on the point. In this case no such relation existed between the Commissioners and the contractors as existed between the parties in *Gidley* v. *Lord Palmerston*, and his Lordship drew the inference from the fact that the present was a case in which the defendants expressly contracted for themselves. That being so, they must be treated as liable under the contract. Mr. Justice Phillimore said that he was of the same opinion. The only question, therefore, was whether the Commissioners of Works were within the class of officials who could sue and be sued for acts done on behalf of the Crown. There was no reason why they should not belong to that class, and in his Lordship's opinion the mere fact of incorporation conferred on them the privilege of suing and imposed on them the liability to be sued. He saw no reason why their liability should be restricted to the Acts with regard to which the liability had been specifically imposed. In his opinion there was a general liability upon the Commissioners to be sued, though the Crown property, if they had any, could not be seized.

New Patents.

These patents are open to opposition until July 1st.

1900.—Stone-Working Machinery.—7,406. F. Trier, 1, Great George Street, Westminster, S.W. The machine, having rolling cutters, is provided with two or more cutters working in steps, the finishing one being held in a toolholder actuated by a stop-rod and rocked automatically.

Sewage Filters.—7,834. D. Cameron, 1, Sylvan Road, Pennsylvania; F. J. Commin, 7, Bedford Circus; and A. J. Martin, Bradninch House: all of Exeter. One of the objects of this invention is to accelerate the filling of filters by storing up a quantity of sewage in a tank and releasing it suddenly. The action is reciprocal, the discharge valve being closed when the admission valve is opened, and *vice versa*, this being effected by floats. Means are provided for locking a lever so that the admission valves cannot be opened until the desired quantity of liquid has accumulated in the tank.

Lifts.—10,426. F. Garside, 14, Bouverie Street, Chester; W. Carter, Bank Villa, Helsby, Cheshire; and The Hydraulic Engineering Co., Ltd., of Chester. On the wall of the lift shaft are fixed as many positive strips as there are floors, and a return or negative strip. A brush is attached to the cage, and the latter has a rope grip operated by a spring and released by a solenoid. The operator sets his brush to rub on the strip corresponding to the floor he wishes to reach. The current then passes and the lift is moved until the floor is arrived at, when the current is automatically broken and the lift brought to a standstill by the rope grip.

Fixing Tiles.—11,403. J. A. Dobbie, Waverley Works, Pattison Street, Leith, N.B. The tile is fixed by a screw in the centre, the head being covered by a button which may be of the same material as the tile.

Metal Hearths.—11,543. W. L. Dennis, 224, Mary Street, Balsall Heath, Birmingham. The hearth is made of a mild-steel plate, enamelled as desired, with a pad of asbestos underneath.

Sewage Screens.—11,632. S. H. Adams, Cumbrae Park Avenue, Harrogate. The screen is so constructed that as it is drawn up it closes and forms a basket in which floating matter is caught. When brought to the surface a suitable part opens and enables the matter to be readily removed.

Automatic Fire Shutters.—11,696. R. L. McIntyre, Toronto, Canada. The shutters are normally held open by a wire. When, however, the temperature reaches a dangerous point a ring on the wire fuses and so allows the shutters to be automatically closed by springs, being securely fastened by dogs.

1901.—Street Sweepers.—2,446. P. Haerst, 566, North Clark Street, Chicago, U.S.A. The machine consists of an adjustable shovel at one end with means for conveying the dirt to a central hopper, while at the opposite end is a circular brush also provided with means for taking the sweepings into the hopper.

Sash Pulleys.—5,319. A. V. Campbell, 6, Coleraine Road, Hornsey, N. The invention consists of a slot-headed screw (passed through the stile) having wheels running on it, with or without mortise linings.

The following specifications were published on Saturday last, and are open to opposition until July 8th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1900.—7,870, Darrah, siphon-flushing cisterns. 8,409, Warren, manufacture of cement. 9,537, Ross, acetylene-gas generators. 9,709, Row, pulleys. 9,819, Reeves, sewage treatment. 10,519, Goddard, windows, fanlights, &c. 10,549, Shaw, lift valves. 11,007, Case, construction of groynes, breakwaters, &c. 11,151, Smith, chimney pots. 11,462, Hodkin, slabs for walls or partitions. 11,508, Ledowsky & Cambiagio, pipe couplings. 11,510, Grube & Sanny, flushing cisterns. 11,518, Follows, cone mills for grinding paint. 12,803, Schmidt, kilns for burning cement and lime. 23,602, Boult (*Segalerba*), ceilings, walls, &c.

1901.—22, Ingham & Langton, machinery for making tapered, radial and other bricks. 3,445, Manke, safety locking-gear for lifts. 4,015, Jackson, pipe wrenches. 4,125, Lake (*National Package Co.*), manufacture of fibrous compositions. 6,421, Smith, water-closets. 6,538, Glassup, Venetian blinds.

CITY OF LONDON LUNATIC ASYLUM.

The chapel and new buildings at the City of London Asylum, Stone, were recently inspected by the Lord Mayor and members of the Corporation, at a state visit to that institution. The improvements which have just been completed were commenced in February, 1898, from plans prepared by the City Surveyor. The male and female hospitals are connected to the east and west ends respectively of the original structure, and are projected southwards into the gardens. The male hospital is not altogether a new building, a portion of the old hospital ward having been reconstructed and formed into a day-room, dining-room and bath-room, with a large dormitory on the first floor. The new building contains a hospital ward with fourteen beds, a day gallery, six single rooms, two attendants' rooms, and other necessary accommodation, all on one floor. The female hospital is a new building on the ground floor, with accommodation for fifty patients. There are two large hospital wards, containing sixteen beds each, one for sick and the other for infirm cases, with a small dormitory for working patients. A separate dining-room is provided. There is also a central day-room with day galleries to the right and left, all facing south.

Opening out of these galleries are nine single rooms and four nurses' rooms. The new laundry block comprises three sections—general, staff and foul. The two last-named are of equal size, and each has a washhouse and drying, airing, finishing, receiving and delivery rooms. The old laundry block has been converted into a block containing the housekeepers' cutting-out rooms, a mess-room and sleeping-rooms for the laundry staff, together with new engine room, and day and sewing and mending rooms, with kitchens, &c. To the west of the laundry is a new mortuary, with laboratory and pathological room. This building is being fitted with conveniences for carrying on the finer pathological investigations now common in most public asylums. The recreation-room, which was formerly the chapel, has been much changed, as a stage 35ft. by 27ft. has been constructed over the kitchen, with two dressing rooms and a fire escape staircase. A new floor for dancing has been laid of 3in. pitch-pine boards.

The chapel is a distinct building, erected about 80yds. to the north of the administrative centre. The style of architecture is Early Perpendicular, and the external walls are faced with flints found in the local chalk quarries, the dressings and finials being of brown Portland stone. Internally it consists of a nave 72ft. by 36ft., lighted by five two-light windows on each side, and a five-light window in the west gable. At the west end there are two entrances, and adjoining each entrance is a small room in case of need for epileptic patients. The floors of the nave and entrances have been laid with wood blocks on a concrete foundation. The hammer-beam roof of the nave, which is a feature of the interior, is also in oak. The chancel, 25ft. wide, is formed with an octagonal eastern end, lighted by a single-light window in each side of the octagon. It is paved with encaustic tiles, and the walls are faced with alabaster in panels. The organ, cased in oak, has been erected by Messrs. Henry Speechly & Son, of the Camden Organ Works, Dalston. Wind is supplied from bellows and feeders fixed in the chamber beneath, and worked by two hydraulic engines. The windows of the chapel are of stained glass, by Messrs. Heaton, Butler & Bayne, the five single-light windows in the chancel representing "King David," "Isaiah," "The Good Shepherd," "St. Paul," and "St. Peter," arranged in the order named. Appropriate emblems of each figure appear in the tracery above. The west window, consisting of five lights and tracery, contains the figures of the "Light of the World" and the four Evangelists, the tracery containing emblems and texts referring to the central figure.

The lighting of the asylum has been improved throughout, and the present opportunity has also been taken to entirely reorganise the fire alarm, tell tale and telephone systems. At the same time the telephone system is being considerably extended so as to comprise both a complete and extensive exchange system, and also direct lines between various parts of the asylum where immediate communication may be required during the night.

The farm, which has recently been enlarged to 170 acres, is now in excellent order, and is of valuable assistance in providing healthy labour and recreation for the rate-paid patients, while at the same time it supplies them with fresh and wholesome food. The old farm buildings, of small value at the time of purchase, have been thoroughly restored, and other new buildings erected to meet requirements for live and dead stock, stores and implements. The electrical installation has been carried out under the supervision of Mr. A. A. Campbell Swinton, C.E., and the alterations to the heating and warming apparatus under that of Mr. W. H. Beck, M.I.M.E. The names of the various contractors are as follows: Washing machines, coppers, &c., Messrs. Bradford & Co., Messrs. Manlove, Alliot & Co., and Messrs. Tullis & Co.; the buildings generally, Mr. Charles Wall, of Chelsea; the water-softening apparatus, The Atkins Filter & Engineering Co.; the heating and warming plant, Messrs. Rosser & Russell; the electric lighting and power installation, Messrs. Mayor & Coulson, Glasgow; and the tell-tale, fire-alarm and telephone work, Messrs. Cox-Walkers, of Darlington. The interior fittings of the chapel have been polished by "Ronuk," Ltd., 83, Upper Thames Street.

NEW HOSPITALS IN VIENNA.

In addition to the great public works projected by the State in Austria, some others of almost equal interest have been decided on by the Vienna Town Council. They are intended as adjuncts to the celebrated medical school, the Wiener Allgemeines Krankenhaus, in the Alserstrasse, which, with its many clinical institutes, its numerous and spacious wards, and its concentration of the best material for clinical observation and research, is the most extolled, and, at the same time, the most criticised public hospital in Europe. While the high reputation of the professors of the Vienna Medical School, and the facilities given to medical men from abroad, are everywhere recognised, the crowded state of the wards, the disturbance due to street traffic and the scarcity of room in the clinical institutes are often the subject of unfavourable comment. It has at last been proposed to erect clinical institutes, with a total of about 2,000 beds, within easy distance from the present Allgemeines Krankenhaus, and, at the same time, away from the noise of heavy traffic, and in a somewhat better atmosphere. The best site available is that now occupied by the Lower Austrian Lunatic Asylum. The proposal is that this and the adjoining Asylum for the Aged and Infirm should be bought by the State for 17½ million kronen. The Town Council has now given its consent, and the Diet of Lower Austria will shortly be asked to vote for the project. No fewer than 220,000 square mètres will be available for building purposes, and it is intended to erect on the site upwards of forty separate pavilions, including seventeen clinical institutes, with 2,000 beds altogether, which is as much as the old Krankenhaus itself contains. It is hoped that the new buildings will be ready within ten years. There will also be a large new hospital for slight cases on the Wilhelminenberg, outside Ottakring, a separate lying-in home and gynæcological institutes at Gersthof, also near the Wiener Wald, a new lunatic asylum for the province further away, a large citizens' asylum for the Viennese at Lainz, and, finally, a large home for convalescents, to be erected by the State in the midst of the Wald. Altogether the new buildings are estimated to cost £2,000,000 sterling, and the expenditure will probably amount to as much again. In Austria provision for the sick is not a private affair; all hospitals and institutes being erected and maintained either by the State or by the towns, or by both together, out of the rates and taxes.

Bricks and Mortar.

APHORISM FOR THE WEEK.

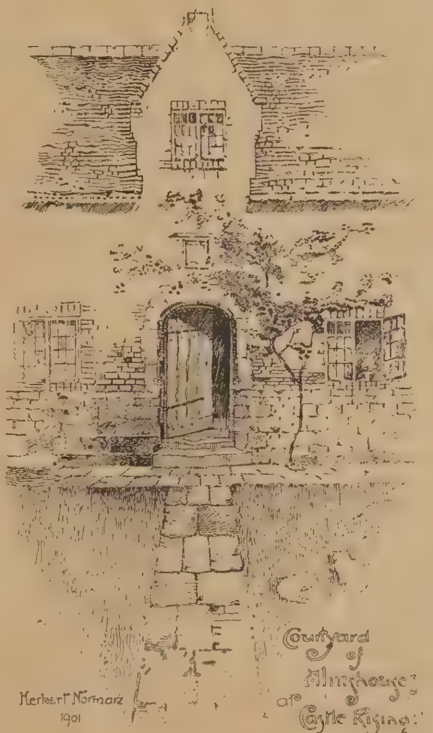
A true artist should put a generous deceit on the spectators, and effect the noblest designs by easy methods.—BURKE.

Our Plates. THE memorial stone of the Shawlands United Free Church, Glasgow, was laid recently. The church occupies an important site at Shawlands Cross, and will, when completed, have a commanding appearance from the road. The main entrance is fronting Shawlands Cross, with massive octagonal turrets on either side 70ft. high, which will form a prominent landmark in the district. The style of architecture is a broad treatment of fifteenth-century Gothic. The church is seated for 1,016 persons, and the pews are specially spaced for comfortable sitting. In addition to the church there are large and small halls, a large session-house seated for sixty-five persons, vestry, classrooms, &c., and a church officer's house. The architects for the work are Messrs. Miller & Black, of 58, Renfield Street, Glasgow.—The small country house by Mr. F. Winton Newman, architect, of 58, Savernake Road, Hampstead, N.W., was designed for a sloping site, and would be built in brick, the first-floor walls covered with rough-cast, and tiles used for the roof. The accommodation on the first floor consists of six bedrooms, bathroom, w.c., &c.

The Late Mr. Gregg. THE death of Mr. Ebenezer Gregg, of 1A, St. Helen's Place, London, E.C., which was announced on p. 307 of our issue for last week, occurred on May 14th at Teighmore, Sutton, Surrey. At the early age of thirteen years Mr. Gregg left school and entered the office of Mr. Sabine, architect, of Old Broad Street, where, before he attained the age of seventeen, he was appointed manager, which post he retained until 1868, when he commenced his practice at 1A, St. Helen's Place. He quickly succeeded in establishing a large and influential business. He was elected a Fellow of the Royal Institute of British Architects in 1870, and at the time of his death had been for many years Examiner on Professional Practice and Specifications. While his practice was chiefly domestic, he was an architect of wide scope. Some of his chief works were: Dr. Barnardo's Village Home at Ilford; officers' quarters, ice house, &c., and offices of the Royal Mail Steam Packet Co., both in Southampton and London; Moody and Sankey's temporary mission hall, to seat 10,000, erected in six weeks; the Banks of Adelaide, New Zealand and New South Wales; and more recently as London architect for the Exploration Company's building in Johannesburg, and the works at 71 and 72, Piccadilly, 24, Austin Friars and 141 and 142, Fenchurch Street. For many years he had acted as surveyor to Jesus College, Cambridge. His death, at age of sixty-eight, will be deeply regretted, especially among students, for whom he always had a helping hand. He will be succeeded by his son, Mr. Theodore Gregg.

The Stock Exchange. THE centenary of the Stock Exchange was recently celebrated. The nomenclature "Stock Exchange" was not coined until 1773, when, on July 14th of that year, some of the leading brokers hired rooms for business purposes at New Jonathan's in Sweeting Alley, and passed a resolution that it should be called "The Stock Exchange"—"which is to be wrote over the door." The brokers then collected sixpence each and christened the house with punch. The first stone of the first real Stock Exchange was laid on May 18th, 1801. The architect of this building was James Peacock. The building, a very plain one with a stone front—except the attic, which was of brick—was opened for business in March, 1802; whereupon admission was regulated by vote by ballot, and ten guineas a year fixed as the subscription, the members at that date numbering 500. The innovation of regulating admission, however, met with bitter opposition from certain quarters. As only the wealthier members of the association had provided the capital for the new building, the Stock Exchance henceforth consisted of two distinct bodies—proprietors and subscribers. Notwithstanding this improved accommodation, the steady increase of business caused an overflow of jobbers and brokers, who sought shelter in the Rotunda of the Bank, where they became a great nuisance, and indeed often created such an uproar that the beadles were provided with rattles, which they sprung when the noise became deafening. These gentry were ejected from the Rotunda in 1838, and the space employed in cashing the dividend warrants of the fundholders. In 1854 Peacock's original Stock Exchange gave place to the present building, erected after the designs of Thomas Allason, jun., which, after being enlarged on one or two occasions, was supplemented in 1885 by a great annexe, equal in size to, but of an entirely different shape from, that of the original building. This was designed by Mr. J. J. Cole, and comprises the additions in Throgmorton Street and in Old Broad Street. The interior of the New Exchange, with its second dome, is lined with marble. Capel Court, in which it stands, was so called from the London residence and place of business of Sir William Capel, ancestor of the Capels, Earls of Essex, and Lord Mayor of London in 1504.

Almshouses at Castle Rising. THE drawing of the courtyard of almshouses at Castle Rising, by Mr. Herbert Norman, is probably somewhat fanciful, as it is made from a very rough pencil sketch jotted down whilst resting in the middle of a cycle ride.



Herbert Norman
1901
Courtyard of Almshouses at Castle Rising.

St. John's Priory Church, Clerkenwell. THE nave of the ancient crypt of the Priory Church of St. John at Clerkenwell, was opened last week for parochial purposes by Earl Egerton of Tatton, Chancellor of the Order of the Hospital of St. John of Jerusalem in England. The crypt is of great antiquity, having been erected by the Knights of the Order of St. John about the year 1100. This was the original chapel, and consists of five bays, with side aisles or chapels to the eastern part, that on the north side being of one bay only, and that on the south of three bays. There are chambers of minor importance on the north side, westward of the aisle. In the latter part of the twelfth century, about the year 1175, the erection of a grand priory church having been determined on, the original chapel, with the extension then made to the eastward, became a crypt under the choir of the new church. This church was consecrated by the Latin Patriarch of Jerusalem, Heraclius, in the year 1185. There is no structure of its kind in London worthy to be compared to the crypt, which, on account of its great antiquity and its historic associations, as well as on account of its intrinsic architectural merit, has well deserved to be rescued from its dilapidated condition and to be put into its present state of good repair. The building has been restored at a cost of £800. The rector is now very anxious to restore the remaining portions of the building, but £500 is still required.

Finsbury Circus. FINSBURY CIRCUS is being completely transformed, more than one half of the circuit being already occupied by lofty stone mansions, in the place of the insignificant brick houses of which many on the opposite side for the present still remain. More than one attempt to get possession of this large open space so close to Moorgate Street and the Bank has been made by railway projectors; but the costly property now rising in this locality, not to speak of that imposing structure the London Institution, must serve still further to daunt them. The circular garden, with its trees and plant and grass plot, will, presumptively, now be equally safe. Like Finsbury Square, which is further from the heart of the City, and is some twenty years older, the circus was originally designed entirely for private residences, and nursery rails may still be noted across the upper windows of some of the original houses. For many years past, however, the houses have been let out in chambers to merchants and other business folk. Finsbury Circus was built about 1815, soon after old Bethlehem Hospital was removed from here to its present site. In front of this quaint old hospital—that is, on the spot now occupied by the circus—was once to be seen a considerable expanse of turf, with sheep feeding and citizens promenading in shady walks.

Richmond Hill. THE view from Richmond Hill, it is feared, may be seriously affected. Land on the Middlesex side of the river, in the parish of Twickenham, is being rapidly covered with bricks and mortar. The Lebanon House and the Marble Hill estates, which form a pleasing feature of the view from the hill, are said to be in danger of attack by the builder. At a meeting of the Twickenham District Council the offer of Lebanon House and grounds for parochial offices, including a Free Library, for a sum of £6,000, was not entertained, although the would-be vendor had offered to contribute £250 for the laying-out of the riverside land as a public garden, and to pay £500 towards the cost of preparing the building for the Council's use. Mr. Max Waechter, a well-known resident of Richmond, has set an excellent example to brother philanthropists by his presentation of Petersham Ait to the borough.

A Gothic Archway at Gray's Inn. WHILE making some minor alterations to the hall of Gray's Inn, the workmen have come across an archway which is at least 400 years old. They were widening a doorway, when they came across stretches of carved stone. The stucco was taken away, and it revealed a beautiful arch of the late Perpendicular style. On each side there had been a coat-of-arms, but the Philistine with the stucco had scraped one of them away to make a good surface for his plaster. The other remained almost perfect. The arms, which are surrounded by the Garter, are those of Charles Brandon, Duke of Suffolk, who was the only Duke of his line, and is not to be confounded with the present Earls of Suffolk. His title was created in 1514, a fact which justifies the view of Mr. Bodley, A.R.A., who, on seeing the arch before the shield had been traced, gave the date as about 1480. The only thing remaining is to trace the connection of Charles Brandon with the Inn. Searches are being made at the British Museum for the purpose. The discovered archway appears in old prints as the front door of the hall; but it was always assumed that the arch had been swept away. Gray's Inn has suffered badly from the stucco fiend, the whole building being once covered, and it is only four or five years since this was removed, showing the hall in its true colour of Elizabethan brick.

THE NEW NORTH BRIDGE STREET, EDINBURGH.

THE eastern half of North Bridge Street, Edinburgh, has now been completed, and marks another important stage in what, when it is completed, will be one of the most important street improvements that Edinburgh has seen for many years. In the reconstruction of the North Bridge, in the widening of the street, the demolition of the old houses, and the erection of the large blocks of buildings, still in progress on the west side, there will have been spent in this city improvement by the Corporation and by private enterprise, within the last few years, over one million sterling of money. The new buildings now finished on the east side are of an imposing character. "The Scotsman" buildings will occupy the other side of North Bridge Street. The improvement on this the main thoroughfare between the Old and the New Town was embodied in the Edinburgh Corporation Act of 1896. The "Scotsman" took the whole of the west side of the street at a cost of £120,000; and on the east side the south block was acquired by the Commercial Bank, which erected thereon a larger building, of which their branch bank forms in the angle a prominent feature. The remainder of the eastern side of the street, two-thirds of the whole, was purchased from the Corporation by Mr. John White, builder, for £70,000, and it is his part of the scheme, extending from the Commercial Bank Buildings to the North Bridge, with a frontage of 357ft. to North Bridge Street and of 120ft. to Jeffrey Street, overlooking the railway valley, that has now been, after the lapse of only two years, completed. The designs were by Messrs. George Beattie & Son, Edinburgh, the architects of the new North British Railway Hotel; and are in the Scottish Baronial style of architecture, with frontages to North Bridge Street and to the north, overlooking the valley. In the angles are turrets surmounted by copper domes; the central feature on the North Bridge Street front is the spacious entrance to the Bon Marché, which at the higher level breaks into a massive gablet flanked with turrets; and, for the rest, the windows have pedimented heads, and there are ornamental string courses and other decorative features. From the North Bridge Street level Mr. White's buildings practically rise five storeys, but they descend by another four to Jeffrey Street, and their foundation is carried down to the railway level. Something like 30,000yds. of earth had to be removed before the rock was found on which to build. This was from 30ft. to 40ft. below Jeffrey Street. On the rock was spread a solid basis of concrete, and the whole of the inner supporting walls were raised therefrom of Staffordshire brick, while the external walls, front and back, are all of polished ashlar, with the shop fronts of red polished Aberdeen granite. The floors are carried on steel girders, and are of fireproof construction. From the foundations to the top of the highest tower is 201ft.; the general elevation along North Bridge Street is about 80ft. in height.

There is a line of shops on North Bridge Street—seven in number, with considerable window space. In the north-east block has been placed an hotel—"The Carlton"—the chief entrance to which, with access from North Bridge Street, has been ingeniously constructed at the end of an open terrace carried on screened girders, along the north face of the building. The hotel descends to Jeffrey Street, where there is an entrance handy to the railway, and a lift works from the basement to the top of the building. There are about 120 rooms in all in the hotel. The main entrance hall and corridor are domed; the corridors on all the floors are spacious, and a feature has been made of the decorations of the public rooms. The commercial room has Elizabethan forms, the restaurant Celtic, the grand dining hall Egyptian, and there is a reading-room in the Adam style, with Chippendale furniture in old rose and the walls panelled in yellow satin wood. One of the floors below the North Bridge Street level of the main building, a spacious hall, lit by electricity, has been set apart as a billiard saloon, in which there are no fewer than thirty-five tables; while the *pièce de resistance* of the block is what is to be known as the Bon Marché, which is 120ft. long, 100ft. in depth, and with a well in the centre 45ft. square, rising from the North Bridge Street level through five floors, where it is crowned with a steel cupola filled in with stained glass. This part of the building has been specially arranged by the architects and builders for the conduct of a large drapery and general business. Its entrance for the arrival and delivery of goods is on the Jeffrey Street level, where are water heating-apparatus, motors for working numerous goods and passenger lifts, and for compressing air for the Lansome cash tubes with which the Bon Marché is freely fitted. By means of this well, and from ranges of windows on each side, this spacious shop, with its five large galleries, is flooded with light. The shop floor and stairs are of marble, the flooring of the galleries is of pitch-pine and oak parquetry, and the well balustrades and internal fittings in solid dark oak. The whole of the west side of the first floor gallery is set apart as a tea and luncheon room, and rooms have been allocated for reading and writing, for music and other entertainments, and a large part of a gallery has been partitioned off as a smoking- and coffee-room for gentlemen. The kitchen is on the top of the house, connected by hoist and Lansome tubes with the restaurant, and there also are work- and dining-rooms for the staff. This block, including the site, has cost about £300,000. Of that sum the Bon Marché, with its stock and furnishings, is credited with something like £150,000.

CELEBRATED ANCIENT BUILDINGS.*

BY JOHN SLATER, B.A., F.R.I.B.A.

IN the preface to the first edition of his "History of Architecture" Mr. Ferguson uses these words: "Beauty in architecture does not reside in pointed or in round arches, in bracket capitals or horizontal architraves, but in thoughtful appropriateness of design and architectural elegance of detail." Although it requires education in design to appreciate the full force of this remark, yet the average man with only hazy notions of art will feel its truth without knowing why; for whether you place him before the majesty of the Parthenon or the ruins of Imperial Rome, or stand him in some great mediæval cathedral where

> " . . . the blessed saints are smiling dumb
> From the rich painted windows of the choir
> On aisle and transept,"

his whole nature will be impressed with the grandeur of the building. Critical analysis may explain for us the wonderful refinement and beauty of the curve of the entasis of a Greek column, may show us the proportions of architrave or pediment, the detail of string course, capital or cusping, but for the great majority the general effect of the whole building will be what will stir the emotions and not the fact of its being in this or that style of architecture.

During the last century there were frequent revivals of styles among us, the chief features of which have been the undue exaltation of that particular style which became fashionable and the excessive depreciation of all others. People are too apt to forget—especially those who pose as leaders and directors of the public in matters of taste—that in the history of the world no system or style, whether in the religious, the political, the social or the artistic sphere, has ever arisen that has not in it some germs of good and was not prompted by some wise reaction against the faults and excrescences of a previous system. And if this is true of the origin, development and decline of the various phases of architectural art known as "styles" through the characteristic features of the buildings which were erected at various periods, still more is it the case in modern times, when we either copy and adapt for our new requirements the methods of former ages, or else are so eager to devise something new that we are ready to acclaim as a new genius the extreme of faddism and eccentricity. The present generation of architects has seen the rise and decline of Modern Gothic whereto has succeeded a modern renaissance, of which we may almost assert with Horace that it appears likely to give birth to a more unworthy offspring. For the present I am going to ask you to accompany me a very long way back down the pathway of Time to a period anterior to all the recognised styles, so that we may see what kind of buildings the ancient peoples of the world erected and how they constructed them, when the sole object of the builders was to put up an edifice that would exactly meet the requirements of those who were to use it and who obtained architectural effect by ornamenting their construction and not by constructing their ornament.

The First Builders.

The origin of building, like everything else, is lost in the mists of antiquity, but the probability is that at first natural shelters, such as caves, would form the dwellings of primeval peoples, and that subsequently the most easily manipulated material, such as wood, would be used for construction, and wooden forms were very frequently reproduced in stone buildings.

The first builders who attained to any architectural skill were that great branch of the old Turanian race which settled on the banks of the Nile and founded the kingdom of Egypt. Here we get the first records of authentic history, but it is absolutely certain that ages and ages must have elapsed before the Egyptians arrived at such a state of civilisation as to enable them to erect the magnificent structures which have so largely defied the tooth of time. Four special periods in Egyptian history stand out pre-eminently as those of great architectural activity. First, the period of what is known as Manetho's fourth dynasty, when the great Pyramids were erected, probably about 3500 to 3000 B.C.; second, the period of the twelfth dynasty, to which belong the tombs at Beni-Hassan; third, the period when Thebes was at the zenith of its power, as shown by the ruins at Luxor and Karnak; and, fourth, the period of the Ptolemies, when the temples at Denderah, Edfou and Philoe were built. I do not propose to inflict upon you any of the theories as to the mythical, mysterious meaning of the Pyramids, because I do not believe in them, but at the risk of telling a thrice-told tale I must draw your attention to some of the principal points of interest in the construction of these gigantic monuments.

The Great Pyramid of Cheops

or Surphis has a base approximately square, the sides being all within a few inches of 760ft. long; the height is 484ft., and it covers an area of 577,600 sq. ft. It was built of limestone, the external casing and the lining of the internal passages and chambers being of granite. It is in the construction of the sepulchral chamber, and the approaches to it that the skill of the builders is most evident. The entrance was on the north face, at a height of 47ft. above the base, from which point a passage about 300ft. long slopes downward at an angle of about 26½ degs. to a chamber cut in the rock 90ft. below the base of the Pyramid. This chamber was not the place of sepulture, but at about 85ft. from the entrance another gallery starts upwards, runs for about 135ft., and then bifurcates, one passage running horizontally to a small chamber known as the Queen's room, and the other continuing upward for another 150ft., where in the heart of the Pyramid is the king's tomb 135ft. perpendicularly above the base. The superincumbent weight above the gallery and the tomb was of course enormous, and the most scientific precautions were taken to prevent these being crushed in.

The great aim of the Egyptian kings was for their bodies to lie undisturbed for 3,000 years, and recent explorations have shown what precautions were taken to prevent their tomb from being approached. The probability is that after depositing the embalmed body in the chamber prepared for it, the workmen blocked up the passage with huge blocks of granite, and then made their way down a small well-hole to the first mentioned passage, and thence to the outer air.

Wooden Construction Imitated in Stone Buildings.

In some of the private tombs near the pyramids are found very interesting examples of the exact imitation of wooden construction in stone buildings, the carving being an exact representation of wooden beams, posts, lintels, &c.

---

* A paper read at the Carpenters' Hall on March 7th, 1901.

In these early examples we find no properly architectural forms, but in the rock-cut tombs of Beni-Hassan, 1,800 years older than the earliest known Greek examples, we have columnar architecture fully developed. On the top of the column proper is a small square slab, or abacus, upon which rest the heavy beams carrying the roof, which has a slightly segmental form, and I think there can be no reasonable doubt that we have here the prototype of the Greek Doric order, and there can be equally no doubt that this form of column was imitated from a wooden post.

The columns at Beni-Hassan are 3ft. 4in. in diameter, and 16ft. 8½in. high, and they have sixteen faces, of which fifteen are fluted and the sixteenth left square for the introduction of hieroglyphics. But, more than this, I believe we have also in these rock-cut tombs the embryo of the perfected Greek temple. The history of the evolution of architectural forms and features has yet to be fully written, but we can scarcely hesitate to take the old Egyptian temple as the early form of the Greek one, knowing as we do the immense influence which Egyptian art and civilisation had on Greece? This is more than ever apparent at a later period, when we find the small temples called Typhonia or Mammisi exhibiting a complete peristylar form.

Karnak.

I must not omit to say a word of the wonderful temple at Karnak, where is the Hypostyle Hall, 334ft. by 167ft., the roof being carried on 134 columns, the centre row being higher than the others, forming a sort of clearstory.

This huge hall, it must be remembered, was only a small part of the whole temple, which, with its entrance court and smaller halls, covered altogether an area of nearly 418,000 sq. ft. Various forms of capitals were used in the early periods, imitations of plants being mainly adopted, such as the lotus bud and the palm leaf, the latter having a particularly graceful outline, and occasionally, at a later date, the capital would be carved into a representation of the head of Isis.

One particular feature of the Egyptian temple is that the walls are not perpendicular, but slope inwards from the base, and it is very probable that their shape is a relic of the time when the tent was the chief abode. The only ornaments used other than painting, which was employed universally, was a bead at the angles, and a sort of cornice formed of a large cavetto with a fillet at the top.

It is only a short time ago since the news came that the large columns of this temple of Karnak are being reinstated. Twenty-seven had fallen, eleven of them only about eighteen months ago. Some of the blocks of stone which form portions of these columns weigh as much as 50 tons, and, curiously enough, precisely the same means are now being employed to take down and re-erect these huge masses of stone as were probably used in their first raising, viz., a long inclined plane.

The main dominating idea of the Egyptian was to build for Eternity, and the stupendous massiveness and solidity of his works chiefly attract one's admiration. But this solidity and massiveness were relieved by the most elaborate and varied system of colouring, and it is almost impossible to conceive of the effect of these enormous temples, the columns and walls of which were all richly painted with figure and flower subject and various geometric patterns. In order to obtain a smooth surface for the application of the colour decoration, Sir Gardiner Wilkinson says distinctly that the Egyptians used to coat their columns even of granite with stucco or plaster. These majestic temples were generally approached by long avenues lined with Colossi or Sphirexes, and at its best period Egyptian sculpture was, in its fidelity to Nature, almost equal to that of the Greeks. In clearing out a deep well near the Pyramids nine statues of Chefren, the builder of the second pyramid, were found, and of one of these the late Sir Richard Owen wrote as follows: "The trunk in anatomical truth is equal to the work of Michael Angelo."

Although not to be compared with the great temple at Karnak, the buildings of the fourth period under the Ptolemies are of considerable interest; but as the influence of Greek art had by this time made itself felt, we can hardly look upon these edifices as strictly coming within the scope of this paper.

Many and interesting have been the discussions as to

The Origin of the Arch

in construction, and the probability is that we shall never know the earliest instance of its use, but all the more recent discoveries point to a far earlier date than was at one time credited for it. The instances are numerous in some very ancient buildings where an arched form of spanning was obtained by projecting horizontal courses of masonry, and then cutting the underside of each course into a concave shape. The Treasury of Atreus at Mycenæ is a well-known example of this, and there is a tomb at Assasseef, in Egypt, where the same kind of construction is found; but Prof. Hayter Lewis assures us that in a tomb at Gizeh, which is almost certainly as old as the fourth dynasty, *i.e.*, about 3000 B.C., he himself found the stones of a flattish arch spanning an opening each of which was cut as voussoirs on lines corresponding with the radius of the curve. Lipsius gives several drawings of brick arches, but without dates, so that there can be no doubt that this form was used by the Egyptians; and it has been a matter of some surprise that the trabeated form alone is met with in the larger monuments which have come down to our own time.

But the fact is that the profound scientific knowledge of building which the Egyptians possessed prevented their using a method of construction which was liable to fail in buildings destined, as they hoped, to last for eternity. And from this point of view they were undoubtedly right. If you get your points of support numerous enough and your horizontal beams massive enough, there is far less risk of failure when all the pressures are vertical than when you have to calculate for oblique thrusts, as in the case of the arch, which threaten to push out the abutments as soon as any weight is placed on the apex.

It has been conjectured that these temples were exceedingly dark and gloomy, and certainly the number of columns must have caused very heavy shadows to be cast, but it is certain that so much labour and pains would not have been expended on the ornamentation of the walls and of the columns themselves had there not been ample means of lighting the interior; and, in fact, the way in which this was done is now pretty well established. In one of the later and smaller temples, that of Isis at Philœ, one may see the small slits close to the top of the wall, and the very deep splay on the inside would allow a flood of light to pour down; in fact, the whole of the wall opposite the opening would be illuminated. I ought not to omit to mention the very curious

Rock-cut Temples,

many of which are found, the most extensive and interesting being at Abou Simbil, in Nubia, built by Rameses II. about 1320 B.C. This temple was adorned at the entrance with four majestic colossal figures of the king, two on each side, in a sitting posture. A narrow passage about 18ft. long leads to a large hall 56ft. long by 52ft. broad, at the end of which a short passage leads into a second hall, beyond which again are smaller chambers. But the curious thing is that on the two sides of the large hall are no less than eight irregularly placed chambers, varying in size from about 48ft. by 13ft. to 13ft. by 10ft. It is possible that these chambers may have been intended to serve as tombs for members of the king's family. These chambers are covered with figure paintings and scenes of all kinds, showing the daily life of those who, as Horace Smith says,

> "Had walked about (how strange the story!)
> In Thebes' streets, three thousand years ago,
> When the Memnonium was in all its glory,
> And Time had not commenced to overthrow
> These temples, palaces and piles stupendous,
> Of which the very ruins are tremendous."

Crossing from Africa into Asia, we find a different race of men, different materials and different methods of building. The probability is that the valleys of the Tigris and the Euphrates were peopled at as early a date as that of the Nile, but no building stone being at hand, we have no remains at all approaching in antiquity those of Egypt The soil being chiefly of clay, sun-dried and burnt bricks formed the staple building material, and with these the enormous Ninevite and Babylonish palaces were constructed. The sun-dried bricks soon became friable, and it is owing to this fact that until comparatively recently, there was nothing but vague tradition to fix the site of many of the most wonderful buildings of antiquity, the ruins appearing to the passing traveller mere heaps of rubbish. But it is to the apparently valueless character of these heaps of rubbish that we owe some of the most interesting discoveries of recent years. It is only within the last half century that we have obtained any reliable information as to the early Asiatic nations and their methods of building, and all the remains of the earlier dynasties are in a terribly ruinous state.

The Chaldæans

are the earliest people who dwelt in this part of the continent, and much of their history is mythical; but as far as can be ascertained from those most competent to form an opinion, there existed a Chaldæan dynasty in the neighbourhood of Babylon from about 2200 B.C. to 1500 B.C., although tradition would attribute a far earlier date to this people. It is very difficult to attempt a restoration of an early Chaldæan temple from the data which we have, but Mr. Ferguson, who had a perfect genius for this kind of study, has attempted it. The Chaldæans were planet-worshippers, and one curious feature of their temples was that they were several storeys in height, the different storeys being placed unsymmetrically, such as the celebrated Birs Nimroud, first described by Rich, and afterwards more fully by Sir Henry Rawlinson. It is highly probable that some such building as this gave rise to the legendary story of the Tower of Babel. Each stage was differently coloured, and dedicated to the seven heavenly spheres. The magnificence of Babylon, her palaces, her hanging gardens and her general luxury have been alluded to so frequently by early Jewish and Greek writers that they have become almost proverbial, but, unfortunately, we can only say of all this, "perierunt etiam ruinæ."

Of the subsequent Ninevite kingdom, however, we fortunately have a very extensive knowledge, thanks to the explorations which have been made during the last half century by Rawlinson, Loftus and Taylor, Layard, Botta and Place. This dynasty lasted from about 1250 B.C. to 625 B.C, when Nineveh was destroyed. No less than seven palaces of the kings of this period have been unearthed, and it is in consequence of the fact of the interior walls being wainscoted with alabaster slabs, upon which were delineated all the exploits of the kings, that we have a complete history of their doings in the same way that the hieroglyphics of Egypt have laid bare their life for us. The earliest of these palaces which have been excavated is one at Nimroud, built about 880 B.C. by Ashur-Bani-Pal, and explored by Sir Henry Layard. The palace formed approximately a square measuring about 330ft. each way, and contained at least six large halls, the largest being 152ft. by 32ft., grouped unsymmetrically round a central court, all the apartments being lined with sculptured slabs of alabaster.

The Palace of Khorsabad.

More recently, however, Messrs. Botta and Place have exhumed a far more complete palace at Khorsabad, formerly called Hisir-Sargon situated about 15 miles from the Tigris, where King Sargon built his country palace about the year 721 B.C. This was probably inferior in size and magnificence to the palaces of Nineveh itself, but it is a most extraordinary pile raised on a mound whose dimensions were about 1,030ft. by 1,120ft., and by far the greater portion of this immense area was covered with buildings. The portals of the palace were approached by a grand double flight of steps, but there was also a slope giving access for vehicles and mounted visitors. The Great Gate gave access to an outer court, round which were grouped stables and out-houses and metal stores. To the north-west of this large court was the residential portion of the palace. and beyond this the state apartments. To the south-west of the Great Court was the harem, and near it the observatory, and closely adjoining the private apartments was the temple.

The discoveries made by Mr. Place were of the most unexpected nature. The entrances to the various courts were magnificent arched gateways of bricks, the voussoirs being carefully moulded to the proper shape and enamelled in various tints, forming a most beautiful pattern, the colours being as vivid as if they had been only lately taken from the kiln. Artificially-burnt bricks were found used for paving, so hard that they rang like a bell; arched covers for sewers and conduits formed of most accurately-moulded radiating bricks, and glazed wall tiles in profusion. The state rooms were all faced with engraved alabaster slabs up to a certain height, and above this colour decoration was used. In the harem the walls were lined with encaustic tiles, with all kinds of figured subjects enamelled in different colours.

Authorities' Opinions on Lighting.

One very interesting and much debated question is as to the method of lighting and roofing these large halls. Mons. Place believes they were vaulted, and he attempts a restoration of the rooms on this basis, which I am bound to say does not recommend itself to my mind, as the effect is very heavy and the lighting could only have been by bull's eyes in the vault. Ferguson, on the other hand, believes—and he has the analogy of existing houses in the country to support his view—that the roof was formed of horizontal beams supported on intermediate wooden columns with moulded caps, the whole covered with dried clay or mud; and he thinks that as the walls were very thick, dwarf columns were placed on them at intervals, and that curtains, or screens, were arranged for shutting out the weather. There are, however, very grave difficulties in the way of accepting this theory. As the first thing which the Assyrian builders did was to raise a large mound of clay, it would be almost impossible to place comparatively small columns on this without any kind of brick pier or foundation under them, and yet in all the palaces that have been examined there has never been found the slightest trace of any such foundation in the internal space between the walls. The wooden columns may very well have perished, but surely some trace of piers would have been found. Moreover, with all the upper portion of the walls open, the draught would have been very great, and there would have been no privacy.

The excessive thickness of the walls would almost suggest some system of vaulting, and one of the French explorers believes he found traces of some sort of lunettes at the springing of the vaults just above the wall line. Sculptors tell us that all the Assyrian wall decorations are arranged so as to be perfectly lit by openings just above the top of the walls, but exactly how this was done will always be a problem wherewith to vex the mind and tax the ingenuity of the antiquarian. Although we have no details of the columns, yet from the small sculptured ornaments on the walls we are able to form a fairly accurate notion of the kind of work which was in vogue, and one of these representations shows what we know as the Ionic volute so unmistakably that we can scarcely doubt that its origin lies with the Assyrian builders, and there can also be little doubt that the carved heads of animals as we find them at Persepolis were also used as caps. It is quite evident that colour was largely used, and that much of the effect of these palaces was due to it; but when compared with the strength and massiveness of the Egyptian buildings, Assyrian architecture must take a very inferior place. We must, however, never forget that they were without any good building stone.

The Persian Builders.

The third great building nation of antiquity were the Persians, who appear to have gained the supremacy in Central Asia about the middle of the sixth century B.C. under Cyrus, and to have retained it until their overthrow by Alexander the Great. There was one province of the Assyrian Empire which became an independent kingdom, viz., Lydia, which has an interest for us historically, though not architecturally, as after it became an independent monarchy under Gyges to the time of Crœsus it was brought very closely into contact with the Greeks of Ionia. It was the Lydian monarchy which was first attacked by the hardy Persian mountaineers under Cyrus, who took Sardis and soon reduced the Asiatic Greeks to a state of tribute. His son Cambyses conquered Egypt, and there can be little doubt that the sight of the magnificent stone buildings in that country fired the monarch's ardour to try and compete with them, and exercised considerable influence on the subsequent architecture of Persia; for before this date there are no ruins where stone had been employed for columns or structural ornament as opposed to surface decoration. Darius gave his attention to consolidating his empire, and commenced the palace at Persepolis which was afterwards largely added to by Xerxes. The grandeur of Persepolis may be gathered from the fact that when it was taken by Alexander, about 330 B.C., the treasure found there was said to have exceeded 120,000 talents, in value equal to about thirty millions sterling.

Persepolitan Palaces

were built on a platform of rock varying in height from 14ft. to 40ft. above the plain, from which they were approached by splendid flights of stairs of very easy rise, and the palaces themselves were raised still higher on elevated terraces. In the ascent from the plain to the northern platform the stairs are 22ft. wide, with treads 15in. wide and risers 3½in. high, and they can be ascended on horseback. The entrances were adorned with human-headed bulls, and the roof was carried by four columns, so that we may call it a distyle hall. On the right of this is the Chehil Minar, the magnificent hexastyle hall of Xerxes, with similar porticos on three sides of it. The bases of all the seventy-two columns have been found *in situ*, so that the plan of the hall is beyond dispute, but there is a difference of opinion as to how the angles were filled up, the probability being that small rooms were constructed here. One of the early explorers found some pipes evidently leading to a drain, and he jumped to the conclusion that no wall could have existed here; and, in fact, Mons. Chipiez has boldly published a restoration of this building without any walls at all, and he professes his belief that there never were any, and that the building was simply a kind of open durbar hall for state occasions, when the monarch could be seen by all those who attended.

No one, however, who has actually inspected the remains has come to this conclusion, and further research shows that the pipes turned off with bends much in the way that our own rain-water pipes would do if they came down the face of a building, and the drain was discovered quite clear of the foundations of the wall.' Furthermore, a little to the right of this huge palace is the smaller one, tetrastyle on plan, built by Darius, and here portions of the wall are still in existence, so that the balance of evidence is against the hall of Xerxes having been entirely open. Still further to the right is a large building, proved by inscriptions to have been erected by Xerxes. This is hexastyle; and here again portions of the walls remain. Ruins of other buildings—including one large dekastyle hall called the Hall of the Hundred Columns, which has been explored by Stolze, and also by Dieulafoy—exist on the terrace, and it is very probable that some of these were never finished, as it has been well said that an Oriental potentate would far rather begin a palace of his own than finish one begun by his predecessor.

The Small Palace of Darius

is specially interesting from the fact that the same king had a tomb for himself cut in the rock about eight miles from Persepolis, on the other side of the river, and he made the entrance to it an almost exact copy of the façade of his palace; and from this we are enabled to gain a very good idea of what the latter was like.

The material used was a fine dark-grey marble, which was obtained in very large blocks, columns 60ft. high being in two, or at most three, segments. It is almost certain, however, that this stone was only used in the walls for the door and window jambs, the main body of the wall being constructed of crude brick, and faced with enamelled or glazed bricks and tiles. The taller of the large columns of the Chehil Minar is 67ft. 4in. from the floor level to the back of the bull's neck. Beams were placed between the bulls' heads, supporting the flat roof, which was of timber and covered with clay. The other column has a capital of great height, probably imitated from Assyrian forms, with curious volutes placed vertically instead of horizontally, and above these were brackets under the beams.

The columns were always fluted, and there is this difference between the Persian and the Egyptian or Grecian columns, that the former have many more flutings than the others—forty, forty-eight and fifty-two flutes are found in the Persepolitan columns, whereas in Egypt there were never more than sixteen, nor more than twenty-four in Greece. The intercolumniations also are always much wider than in the Greek examples. I may mention that the columns of the Parthenon were only 34ft. in height; and this will give some notion of the magnificence of Xerxes's splendid hall.

I would specially call your attention to the base of these columns, which appears to me to combine simplicity, gracefulness and correct construction in a very remarkable way, and it is curious that the Greeks seem never to have adopted this form of base, although one very similar has been found in some excavations at Rome. An ornamented Persepolitan base would be a very effective addition to the Corinthian or Composite orders. The Persian kings had other palaces at Ecbatana and Susa, the latter of which has been explored by Mons. and Madame Dieulafoy, and some very interesting discoveries of wall decoration were made. No mention of Persian architecture would be complete without a reference to the ruins of some

Remarkable Buildings in the Province of Fars,

which have afforded a very fertile field for discussions and differences of opinion among archæologists. Nearly all the buildings which I have described are in the trabeated style, but at Feruz-Abad and Sarvistan are the remains of a very different kind of building. It was first described by Flandon and Coste, and has more recently been visited by Mons. Dieulafoy. This is an isolated building about 135ft. 6in. long and 118ft. broad. The main entrance is in the west front, where is a lofty vaulted gateway 47ft. wide and 19ft. deep, with two small gateways on each side, the wall spaces between and on each side of the gateway being enriched with engaged columns of about 27in. diameter, with neither caps nor bases. On the north side there is another deep vaulted gateway giving access to a hall with two ranges of short thick-set columns. In the interior is a court nearly 42ft. square, with a lofty ovoid dome over it, and on the south there is another pillared hall with a smaller domed apartment. The domes and vaults are of well-baked brick, the corner walls are cased with stone, and the columns are of stone plastered over. Now it is extremely probable that these, and similar buildings, were the precursors of the later mosques, but what is their date? Mons. Dieulafoy considers that they have affinities with such buildings as at Khorsabad, with its vaulted gateways, and puts them as co-eval with the Persepolitan buildings, about 450 B.C., and if this could be proved it would be another instance of the very early date of arched forms. But the more generally recognised view is that they belong to a much later period, either to the time of the Arsacid dynasty, or possibly as late as the Sassanid. At any rate, they are worthy of a passing notice, situated as they are in the heart of the desert, and their history will probably never be elucidated.

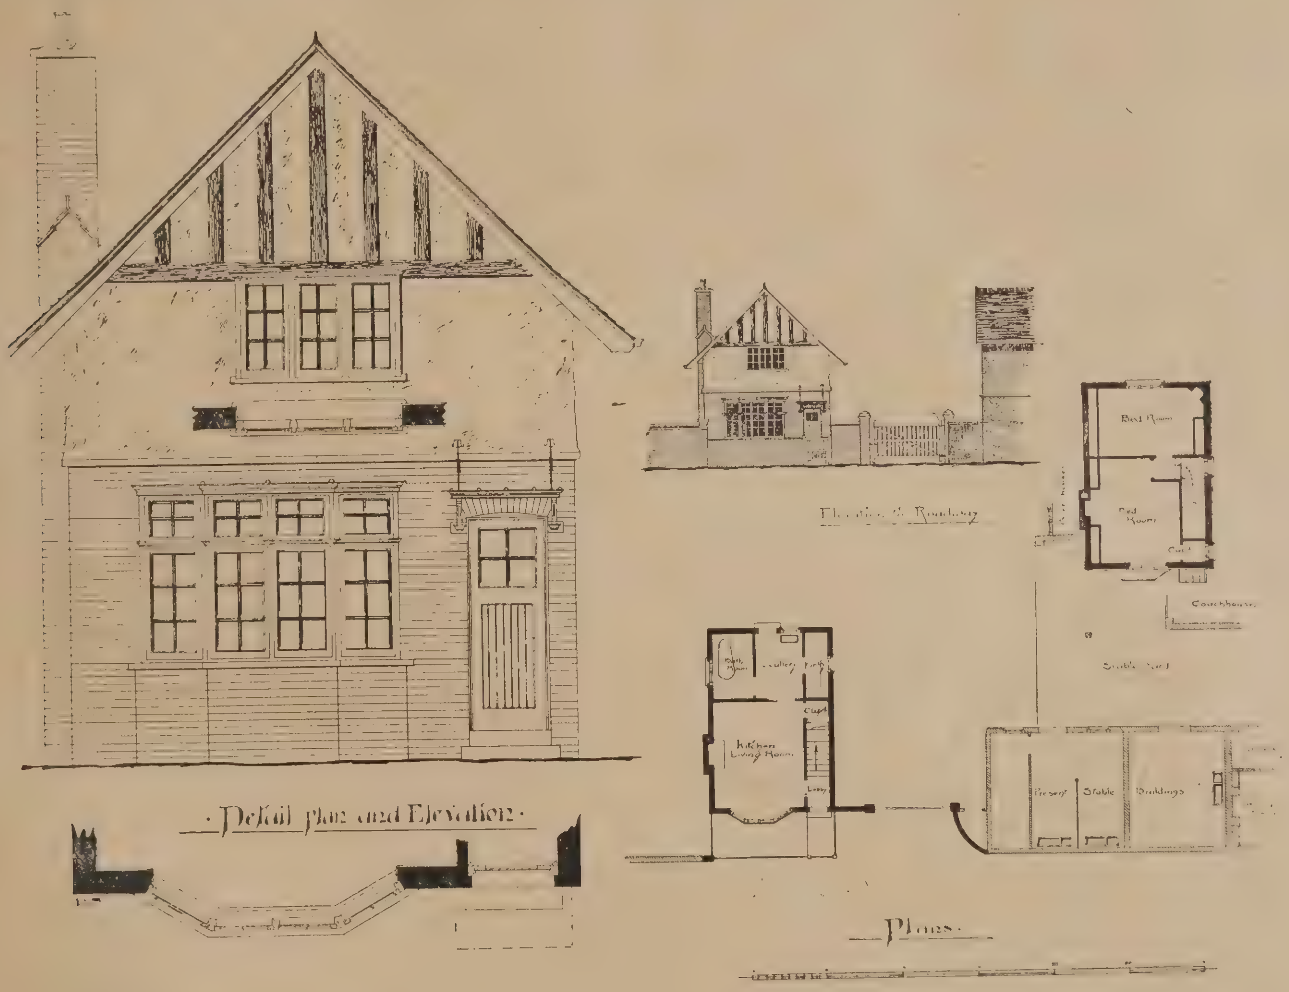
Greek and Persian Art.

There is one very curious point, that must strike every student of ancient art in connection with Persian architecture, which attained its highest perfection between about 500 B.C. and 450 B.C. Now, about 598 B.C. were commenced the Temple of Diana at Ephesus and the Temple of Juno at Samos; later in the same century the Temple of Olympian Zeus at Athens was built, the Temple of Panhellenic Zeus at Egina towards the end of the century, and the Parthenon, the crowning glory of Greek architecture, was built in 438 B.C. Herodotus tells us that the ships of Darius and Xerxes swept the Ægean, Greek mercenaries entered the armies of the great king, envoys from various Greek states, political refugees like Demaratus and Themistocles, doctors like Ktesias, and others—all formed part of the court of the Persian monarchs; and, in fact, the relations between Greece and Persia were very extensive. How is it, then, that so little Greek influence is manifest in these Persian buildings? The answer is that the two nations were in their politics, their religion and their art utterly dissimilar; that Persia was in all essentials an Asiatic power, and allied to the older Assyrian civilisation; and that her art was modelled on its lines. After the Macedonian conquest we find the Hellenic genius asserting itself all over Asia in the wake of Alexander the Great, when architects from Greece were largely employed by the Asiatic satraps.

Explorations in Phrygia.

It must not be imagined that the three great monarchies which we have been considering were the only ones in the ancient world where a high standard of art prevailed. Many brave men lived before Agamemnon, as Horace tells us, whose names have perished because no inspired bard has sung their exploits; and scattered over the eastern world are the ruins of cities which we know to have existed, but which had been absolutely forgotten and their sites lost 1,800 years ago, when Strabo wrote; and in many cases the districts in which these cities were are now so far removed from the track of civilisation that they are rarely visited. Ancient Phrygia, for instance—the history of which is almost entirely legendary—has recently opened up for us some secrets of her long-forgotten past, thanks to the enterprise of the Society for the Promotion of Hellenic Studies. From these Phrygian explorations some further interesting examples of the imitation of wooden forms in stone have been discovered. In one case is a representation carved in the rock of one of our commonest wooden forms of roof. The upper part of this chamber was carried by two piers cut out of the rock and formed into columns, one of which has been knocked down, but the other is standing and is decorated at the top with an ornament which can scarcely be called a cap, as it is only carved on one side, which was subsequently largely used in Greek architecture. This ornament is distinctly unsuited to a column, but it is applicable to a pilaster, and must have been imitated by a mason who had seen the ornament in a different position. Curiously enough, on a stele discovered by Mons. Place at Khorsabad almost an exactly similar ornament was found.

It is a curious circumstance that although Indian traditions go back to as remote a date as 3100 B.C. no remains exist of any stone buildings earlier than the time of King Asoka, who reigned between 272 B.C. and 236 B.C. Previously to that timber must have been almost exclusively used, and wooden forms have left their print on much of the native Indian architecture to the present day. We know that Alexander's conquests extended into India, and it would not be surprising to find traces of Persian art in some of the Indian buildings; in fact, at Cabul is a pillar so strongly resembling the Persepolitan column in its upper members that it must be a copy probably made from memory, and doubtless many other such might be found. But I have no time left to indulge in a hunt after these sporadic reminders of the architecture of the ancient world, nor to touch upon the wonderful buildings of Cambodia or the relics of ancient civilisations which have been found in the heart of the American continent. Although explorers have unearthed for us many valuable remains, it must be perfectly certain that there still remain buried—sometimes beneath the sand of the desert, sometimes under the waves of the encroaching sea, and sometimes under the accumulated débris of centuries, upon which other modern buildings have been erected—relics of antiquity which far transcend any that have been discovered. In many places tradition lingers long, and in the course of years enhances and exaggerates, but there is generally a solid substratum of truth at the bottom of it, and we may yet live to see many more of these celebrated ancient buildings disclose to us the secret of their fame. In other places tradition completely dies out, and it is only chance that leads to most valuable discoveries. Quite recently we have heard of most wonderful discoveries in the island of Crete, where explorations are being systematically carried on with the most unexpected results. At Knossos the palace and throne of King Minos, who was considered to be almost a legendary monarch, have been unearthed, and the interest of these discoveries will probably be greater even than those of Dr. Schlieman at Troy and Mycenæ. The very earliest beginnings of Greek architecture are here revealed, and its further affinities with Egypt are made clear. As the world shrinks and its by-ways become opened up we are continually finding unexpected remains of building nations—even in Mashonaland such have been only recently discovered—but the builders have entirely disappeared. It is not too much to say that wherever over the whole face of the earth explorers have come upon the relics, in stone or brick, of a remote civilisation, their wonder has been excited at the solidity, and in many cases the high artistic quality, of the work; and it appears to me, despite all our modern resources and all the discoveries of science in these latter days that no one can study such buildings as I have brought to your notice this evening without having a little of his modern conceit taken out of him, for truly do the remains testify that in energy, in intelligence and in skill there must have been giants in those days.



COACHMAN'S COTTAGE, "BLEAK HOUSE," PATRINGTON, NEAR HULL. ALBERT C. FREEMAN, ARCHITECT.

A COACHMAN'S COTTAGE.

THE addition of a coachman's cottage (illustrated on this page) to "Bleak House," Patrington, near Hull, is for Dr. W. H. Coates, M.D. It is proposed to be faced with red facing bricks, with rough-cast plasterwork to the first-floor external walls, and half timber work and barge boards to the gables. The roof is to be covered with red tiles. The design is by Mr. Albert C. Freeman, architect, of London, who carried out the library and other additions to the house some time ago.

New Mission Premises for the Barbican Mission to the Jews have been erected in the Whitechapel Road as a memorial to the late Prebendary Gordon Calthrop, vicar of St. Augustine's, Highbury, and first president of the mission. The total cost of the building, including purchase of the site, furnishing, &c., has been about £8,700.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Apportioned Cost of Repairs to Adjoining Drains.

LONDON, E.C.—ARCHITECT writes: "On p. 287 of your issue for May 15th, under the heading 'Apportioned Cost of Repairs to Adjoining Drains,' your expert says, in answer to 'A.H.': 'If the drain in question is a "combined private drain," and not a "sewer" vested in the local sanitary authority, then the cost of reconstructing or repairing the combined drain should be kept quite distinct from other work, and divided equally between the owners of the two houses draining into it.' Under what Act of Parliament, or under what decision in a court of law, is this question decided?"

The reply referred to is given as constituting a reasonable basis for the amicable and equitable division of the expense of reconstructing a combined private drain amongst the property owners concerned, and is in accordance with the general principle set forth in the Public Health (Amendment) Act of 1890. Under section 19 of this Act it is laid down that "where two or more houses belonging to different owners are connected with a public sewer by a single private drain, an application may be made under section 41 of the Public Health Act, 1875 (relating to complaints as to nuisances from drains), and the council may recover any expenses incurred by them in executing any works under the powers conferred on them by that section by the owners of the houses in such shares and proportions as shall be settled by the surveyor or (in case of dispute) by a court of summary jurisdiction." The legal powers conferred on sanitary authorities within the metropolis when dealing with combined private drains will be found in the Metropolis Local Management Act, 1855, the Metropolis Local Management (Amendment) Act, 1862, &c. In all cases of reconstruction of combined private drains it is most desirable that the property owners concerned should mutually agree to pay their fair share of the cost. If any such friendly arrangement is impossible, and the necessary reconstruction required by the local authority is allowed to go by default, then the local authority will execute the necessary works, and charge or apportion the cost as may be considered necessary, according to the particular circumstances affecting the case and locality.

T. E. C.

Powers of County Court Judge respecting an Arbitrator's Award.

PETERBOROUGH.—M. H. writes: "Some time ago a report was given in your columns of an important case relative to architects as arbitrators. An arbitrator having issued his award, what are the powers of a county court judge in respect to it?"

The case you quote (see p. 79 of the BUILDERS' JOURNAL for March 6th last) came to this. The architect certified that a certain sum was due from the building owner to the contractor. The contract provided that this certificate should be conclusive evidence of the work "having been duly completed, and that the contractor was entitled to receive payment of the final balance." The building owner alleged that the architect had measured up the work negligently, and had made him pay too much, and claimed damages. The Court of Appeal, however, held that inasmuch as the architect had really been an arbitrator between the parties, he could not be made liable for negligence. This decision does not affect the powers of the county court judge with reference to the certificate. By the clause quoted, the contractor could sue under his contract.

A. O. H.

Boiler Chimney-shaft.

NIMAJNEB writes: "I am building a boiler chimney-shaft, and propose to line it with firebrick 4½in. thick to a height of about 25ft. The shaft is octagonal, and measures 2ft. 6in. in the clear inside of lining. Between the latter and the main walls of the shaft I have a ventilated cavity. Should the firebrick lining be tied or bonded in any way to the main walls by ties bridging over the cavity? The object of a cavity is, I presume, to allow expansion, &c. If the lining be tied or bonded at all to the main walls, would not the object of the cavity be defeated and cracks occur where the bonding was? If not bonded to main walls, is there any danger of the lining collapsing? If lining should be secured to the main walls, what is the best form of tie or bonding under the circumstances—iron or firebrick?"

The firebrick lining should not be tied or bonded to the main walls, the object being to allow free expansion. Twenty feet is generally considered high enough for a half-brick firebrick lining for a boiler shaft. A sailing course should project immediately over the cavity from inside of shaft, to prevent dust and soot falling between and blocking it so as to prevent expansion. The cavity does not require to be ventilated; any opening made into it would spoil the draught.

HENRY ADAMS.

Sketching at Beverley.

DUNFERMLINE.—SKETCHER writes: "I propose going for a fortnight's holiday to Beverley, Yorkshire. Kindly mention one or two places of architectural interest in the neighbourhood?"

In Beverley itself there is plenty of interest, both in the Minster and the church of St. Mary; but although it is generally difficult to make a mistake in Yorkshire, there seems to be little of value that is easily reached by rail from Beverley, except Headon Church, near Hull, with its pure Early English north transept and its early Perpendicular central tower. It would be quite possible, however, to work round from Hull to Howden, and thence on to Selby and York, in all of which places there is ample material for study.

G. A. T. M.

Shivers.

NEWCASTLE-ON-TYNE.—G. C. writes: "In the recent South Kensington examination in building construction a question was asked, What is a shiner? What is this?"

Apparently this is a misprint for "shiver"—a spall, or small splinter.

Liability for the Non-Fulfilment of Contract.

PERPLEXED writes: "The answer to my question on p. 286 of your issue for May 15th is rather disappointing. I wish to know whether there are any legal decisions bearing upon the question. If so, kindly quote them."

Matters of this kind depend so largely upon the *exact* wording of the contract both between architect and employer, and employer and builder, and the conditions, that only general answers can be given together, with the advice that a local solicitor should be consulted. We know of no decided case upon the precise point raised.

G. A. T. M.

Damage due to Water Leakage.

WOODHOUSE.—MASON writes: "I live in my own house. The next-door sink is at the other side of a partition between the two houses. There is a leakage of water, and it oozes through the wall, destroying my paper. The landlord has had a man to look at it, but the nuisance continues. What is the best action to adopt?"

Write or interview the owner of the adjoining house, requesting him in a friendly manner to effectually repair the defective water-pipe and make good the damage caused to your property. If you are unable to obtain a satisfactory settlement in this way, consult a local solicitor of good standing.

T. E. C.

By-laws relating to Chimney Openings.

PETERSFIELD.—H. T. K. writes: "(1) Model By-law 42 requires the back of a kitchen chimney opening in a party wall to be at least 9in. thick to the height of at least 6ft. above such chimney opening, and such thickness to be continued at the back of the flue. Does this mean the whole height of the flue, or only to the height of 6ft. above the opening? (2) The by-law further provides that the back of every other chimney opening not being in an external wall shall be 9in. thick from the hearth up to the height of 12in. above such opening. Does this mean that the flue above this specified height may have a backing of 4½in. only, even if in a party wall, as seemingly implied by the previous by-law?"

In questions of this description it is desirable to quote the entire section of the by-law, and not incomplete or detached portions, as such extracts may be entirely contradictory when separated from the context. (1) The back of the flue of a kitchen chimney constructed in a party wall should not be less than 9in. thick for the whole of the height in which such flue is built in connection with the party wall. (2) Under this by-law the back of every other chimney opening and flue (not being in an external wall) must be 9in. thick up to a height of 12in. above the chimney opening. The remainder of the flue may be 4½in. thick unless prohibited by any other section or by-law.

T. E. C.

Engineering Notes.

London Tramways Extensions.—The Select Committee of the House of Commons have declared to be proved the preamble of the Bill of the London County Council seeking powers to construct numerous junction lines of tramway and several new tramways, principally in the south of London, the whole of the proposed lines, together with the existing systems, to be worked by electricity, except so much as refers to the Farringdon Road extension and the York Road, Lambeth, tramways, which are thus rejected.

The Tunnel to the Isle of Wight.—Messrs. P. W. and C. S. Meik, the engineers entrusted with the building of the tunnel to connect England with the Isle of Wight, hope to begin operations in September. It is more than likely that the trains will be propelled by electric motors, making it the only tunnel of the kind in the kingdom. The total length of the new line will be eight miles, but that of the tunnel proper will be no more than two miles and a quarter. Of the estimated cost of £550,000 as much as £400,000 will be spent on boring under the Solent. When the project is completed passengers will be carried from London to the Isle of Wight in the record time of two hours and a half.

Mr. Henry Brunton, M.I.C.E., whose death occurred recently, held a remarkable place in the history of the international relations between Japan and this country. The treaty negotiated by Lord Elgin with Japan stipulated that the coast should be lighted and buoyed for the safety of general navigation. When Sir Harry Parkes drew the attention of the Japanese Government, in 1868, to this clause, which had not been fulfilled, he was informed that they were perfectly willing to carry out their obligations, but their ignorance and inexperience made them unable to fulfil them without further advice. Finally, Mr. Brunton was selected to aid them, on the advice of Messrs. Stevenson, of the Scotch Lighthouse Board. On his arrival in Japan he found that the work before him was not so simple as building lighthouses in his native country. Sir Harry Parkes persuaded the English admiral then in China to let him have the use of the despatch steamer "Manila," and in that Mr. Brunton and his staff made a tour round the coasts of Japan, visiting some twenty sites and making the necessary surveys and calculations. In ten years' time he had built fifty lighthouses, and had arranged a complete Government department for their maintenance. He further reported on, and made the plans for, the removal of the bars at the mouth of the rivers, on which the Government officials are even yet working. His design for the harbour in Yokohama Bay was thought too expensive by the Government at the time, but that subsequently adopted was on his lines. He also started the telegraph system in Japan, and introduced methods of constructing bridges, buildings, &c., to withstand earthquake shocks. On the completion of his lighthouse work he returned to this country.

THE RISE AND DEVELOPMENT OF EGYPTIAN ART.*

By Professor FLINDERS PETRIE.

WHEN a summary of what was known on early art in Egypt was read by me here eight years ago, I had to say that not a single sculpture was dated before the fourth dynasty, and that the rise and course of this art were still buried. But every year since then has yielded some portion of the early art, until now we can trace it from the very beginning.

Our first view of any civilisation in Egypt starts with the beginning of cultivable land, on the first deposits of Nile soil, about 7000 B.C. Before that Egypt was only a rocky gorge frequented by wild animals and palæolithic hunters. The oldest graves that are known are of a settled pastoral people, and show that pottery and small quantities of copper were already possessed by the rude inhabitants. But this civilisation rapidly developed in the fertile valley of the Nile, and

The First Steps of Art

are seen in the white clay paintings on the red pottery vases. These paintings are usually figures of goats, but some are known of hippopotami and human figures. This style of pottery painting disappeared in the early part of the prehistoric age, only being found in the first tenth of the known graves.

The carving of slate palettes in animal forms begins at its best in almost the earliest graves, and underwent continued degradation through the whole prehistoric period. The best work on slate was that of the incised lines. The favourite scope for animal figures was in the ivory and bone carvings on the heads of combs. They are, however, but rudely treated, and no fine or spirited work is found among them. The general low level of the figure work among these people co-existed with a very fine taste and skill in purely mechanical outline, as seen in the pottery and stone vases.

Of the latter part of the prehistoric age many examples of drawing remain on the painted pottery; and of the same style, but more varied, are the paintings on a tomb.

Prehistoric and Dynastic Art.

There is a strong contrast between the prehistoric and the dynastic art. The former was, at its best, far inferior to the rough work of the later people; while in mechanical ability the later people show no marked improvement, and in some respects—such as flint work—they never reached the prehistoric level.

The earliest work that may be assigned to the dynastic race is the first statue of the god Min from Koptos, made rather before 5000 B.C. The figure is of the rudest, a long block with legs and arms marked by grooving; yet on the side of it, roughly hammered on the surface, is an excellent head of a stag and two *pteroceras* shells. On another statue of Min which is more elaborated there are several carvings, of which the hyæna chasing a calf is the best, showing a good sense of expression and character.

At Koptos were also found pieces of pottery figures in the round, which explain how the Egyptians attained at once such a fine style in sculpture when they adopted working in stone. The pottery is only of coarse clay, black inside, but a fine face of hæmatite was burnished on the surface, which gave a high finish to the work. Only fragments were found at Koptos, but a noble figure of a lion comes from Hierakonpolis.

From the same site comes our next half-dozen examples of the art shortly before the first dynasty. A great mass of ivory figures have shown what abundance of such work there was in this age, and how complete a mastery of carving had been attained. Beside the good proportions of the figures, we see in the carving of the heads real portraiture, as true to a type as any of later time. In all this work, though traces of archaic style cling to it, yet the power of expression is of the best, as showing character and race.

A rougher kind of work appears in the little glazed pottery figures of animals of the same period, which are interesting as showing the freedom of using glazes at so early a date. Glazed tiles were also made at this time for wall decoration, and continued into the third dynasty. The fine work in hard stones seems to have come to a climax under these earlier kings; as nothing has exceeded in size and work the great syenite bowl from Hierakonpolis.

Carved Slate Palettes.

We now come to the most important of early monuments, the carved slate palettes. And since the discovery of that of Narmer, which is now fixed by his tomb as being just before Mena, we may date all such carving to the pre-Menite kings. The only slate with entirely animal figures was found at Hierakonpolis. The work is of the same stamp as other examples that we have noticed, somewhat archaic but full of vitality and character.

One of the largest slates shows a long procession of warriors bearing different weapons. The style is more flat and cheap in effect, grooved lines being freely used. The scenes have not that directness and unity that we see in the other examples; and altogether, though full of interest in the subjects, it is the poorest of all in the art. The reverse of it is flat. Pieces that belong to one of the finest slates make us greatly regret that no more of it is known. One side shows a beautiful group of two young giraffes and a palm tree. In the sense of artistic grace and design this is the finest piece of such work that is known.

The outline work attained its full growth in the time of Mena, as seen on some of the ivory vases. The figure of a hawk is practically the same as in any later period; the style is complete, and no trace remains of the archaism of the previous reign. The fragment of a bull's head on another ivory vase shows that carving in relief was not quite so far advanced.

The main examples of decoration and technical work of this time are the bracelets of the queen, found so unexpectedly this spring upon her arm. The band of hawks in alternate turquoise and gold is a record of the culmination of the art. This bracelet just embodies the changes of that critical point in the history of the art; a change as rapid and decisive as the change in Greek art, from the pre-Persian to the Phedian sculpture.

In the Reign of Zet.

On coming to the next reign—that of King Zet, the third of the dynasty—the incised carving is seen to have been fully carried out on the stone bowls. The cutting is as flowing on this hard metamorphic slate as on the soft ivory.

The richness of the dynasty seems to have culminated under the fifth king, Den; he was the first king who used stone in his tomb, and he grandly paved the whole of it with slabs of pink and grey granite, a labour no other king attempted to copy for centuries afterwards. He first had a pictorial royal seal showing his herculean labours in wrestling with the hippopotamus, and hooking the crocodile by its jaws. And the only relief inscription on a vase belongs to him, a splendidly cut panel on a large alabaster jar. He was distinctly the magnifico of that age; the work less severe and noble than that of Zet, but more showy and sumptuous.

Furniture Legs.

Throughout the earlier part of the dynasty there was a standard decoration for the legs of stools or other furniture, of carving them in the conventionalised form of bulls' legs. This pattern descended from prehistoric graves, as it is found on a large scale in wood at about four-fifths through the prehistoric age. The work of these bulls' legs is remarkable for the highly conventional decoration of the vein lines; and it might be mistaken for *cinque cento* design rather than credited to the beginning of history.

Lastly, we see here the earliest statue that is yet known, belonging to the middle of the second dynasty, or about 4350 B.C. It is obviously a long way from the archaic style, and we have yet to find a long series of sculpture to lead up to this. The head is highly finished, and more natural in the form of the eye and mouth than any of the crowd of royal statues which filled the succeeding ages.

It is to the temple site of Abydos that we must look for the carvings on slate, and perhaps the royal statues, which will more completely fill our view of the rise of art; and it is that site to which I hope to give the next three years of work in Egypt.

Keystones.

A Stained-Glass Window has been placed in St. Giles's Cathedral, Edinburgh, in memory of Major-General Wauchope.

A New Church in Edinburgh has been erected for the Fountainbridge United Free Church congregation at Murchiston.

A New Pavilion for the Darwen Golf Club was opened recently on the links at Winter Hill. The pavilion, which has cost close upon £300, overlooks the first tee. It is a timber erection with a corrugated iron roof. The pavilion has been erected under the supervision of Mr. G. G. Sames.

A New Church at Smethwick, dedicated to St. Stephen, is about to be erected in the parish of Holy Trinity, at a cost of £4,750, from the design, of Mr. F. T. Beck, architect, of Wolverhampton. The contract for the new church has been secured by Messrs. J. Harley & Sons, of Smethwick.

Changes of Address.—Professor Charles Gourlay, A.R.I.B.A., has removed from 2, Oakvale, Gibson Street to 30, Hamilton Drive, Hillhead, Glasgow. Messrs. Thomas W. Aldwinckle, F.R.I.B.A. & Son have removed their offices from 1, Victoria Street, Westminster, S.W., to 20, Denman Street, London Bridge, S.E.

The New Inghamite Chapel at Cotton Tree, Colne, built by a section of people which split from the Winewall body, was opened recently. The new erection is built of Winewall stone, and consists of an upper hall, which will seat about 400 people, and a large lecture-room on the ground floor. This latter will be used as a Sunday-school until the church has developed. The cost of the new building is estimated at £2,000.

The Edinburgh Architectural Association recently visited Dunfermline, where, through the kindness of Colonel Hunt of Pittencrieff, they were enabled to inspect the old House of Pittencrieff, with its various old articles of furniture, pictures, &c. Mr. John Houston, architect, of Dunfermline, acted as leader, and read descriptive accounts of the house and the picturesque glen in which it stands. The party then drove to Pitfirrane, where they were received by Sir Arthur Halkett, Bart., by whose courtesy the splendid old pile was examined, and who gave a most interesting account of the house, and recalled how it had been inhabited by the Halketts of Pitfirrane since 1437.

A New Infants' School is being erected for the Preston Church Day Schools' Association in Plungington Road. Accommodation is provided for 300 children, and the cost has been about £2,400. The school will contain a schoolroom, 66ft. by 24ft., to accommodate 190, to be divided by movable partitions to form classrooms. There will also be a class-room to hold sixty, and a babies' room for a similar number. Adjoining these will be a mistress's room, spacious cloak and lavatory rooms, &c. The yards are spacious. The materials employed in the building of the school are brick and stone for the outside, the roofs being of open timber. All the rooms will have a glazed brick dado about 4ft. high. The architects are Messrs. Myres, Veevers & Myres, and the contractors Messrs. T. Croft & Sons, of Preston.

Sheffield Society of Architects and Surveyors.—The fourteenth annual report (for the year ending April last) states that the membership now stands at 111, as compared with 109 last year. Reference is made to the objections raised by the sub-committee of the Highway Committee respecting the construction of area lights in footpaths, as reported on p. 217 of our issue for April 24th last. The statement of accounts shows a balance in the bank of £99 4s. 6d. We notice several misprints in the pamphlet—such as "Pryor" for "Prior," "Dauber" for "Dawber," "Bryden" for "Brydon," "Slator" for "Slater," "Baggaley" for "Baggallay," while in one case we read "Berresford Pite" instead of "Beresford Pite." "Palladio Archittura" is also given for Palladio's "Architettura." It is so easy to verify the names that we are surprised to see them misspelt.

---

* Extracts from a paper read before the Applied Art Section of the Society of Arts on May 21st last.

A Statue of Queen Victoria is to be erected in Halifax at a cost of about £2,500.

Staincliffe Church has been reopened after re-painting and decorating by Messrs. Powell Bros., of Park Square, Leeds, at a cost of about £207.

New Town Hall for Marylebone.—The Improvements Committee of the Marylebone Borough Council recommend the latter to acquire a site of 28,000 sq. ft. extending from Circus Street to Wyndham Street, Marylebone Road, whereon to erect a town hall which shall comprise a large hall for public meetings, &c.

The Liverpool Diocesan Church House has just been completed. The building occupies a prominent site in one of the main thoroughfares of the city, and, besides a diocesan board-room and well-equipped library, contains accommodation for the various agencies connected with the Church of England in the diocese.

Coldbath Fields Prison, with its huge and gloomy gateway, of which but a vestige remains, will shortly be a thing of the past. The Post Office at Mount Pleasant has taken possession of the "House of Correction," which was opened in 1794, and closed its doors to the guilty public in accordance with the provisions of the Prisons Act of 1877.

The Parish Church of Llanrhidian, Gower, was reopened recently, after restoration. The work of constructing a new roof for the chancel, repairing the ceiling of the nave and renovating the masonry has been accomplished at an expense of £350. The chancel has also been refitted with choir-stalls, communion-table, &c., and stained-glass windows were presented by several donors.

Keppel Street Baptist Chapel will soon be demolished in consequence of the changes which are taking place upon the Duke of Bedford's London estate. It has been found impossible to modify the plans to such an extent as to permit of its retention; but the ground landlord has contributed one hundred guineas towards the provision of a new building elsewhere. Keppel Street Chapel dates from 1795, and it then stood alone in the fields.

A New Kursaal at Southend is being erected in the endeavour to emulate the glories of Blackpool. The kursaal, which has been building for more than two years, is now announced to be opened on the first Monday in July. It has cost £100,000. It includes a shop arcade 120yd. long; a tower, of which only the foundations are yet laid, 530ft. high; a ball-room for 2,000 dancers; a dining hall which will accommodate 1,000 persons; and a palmarium, balconies, billiard-room, cricket ground and cycle track.

Ruskin's Grave.—The memorial stone which has been placed on the grave of John Ruskin, in Coniston Churchyard, forms a cross of the type lately revived from the models of the age before the Norman Conquest. It was cut from the neighbouring Tiberthwaite quarries, and, with its base, is a little over 9ft. high. The only inscription gives the name and dates of birth and death. The remainder of the stone is beautifully carved with symbolical representations of Ruskin's principal works, from the designs of Mr. W. G. Collingwood, of Coniston. The sculptor was Mr. H. T. Miles, of Ulverston.

A Memorial of the Late Duke of Westminster in connection with his efforts to provide sites for working-class dwellings on his London estate was unveiled last week. The memorial consists of a bronze tablet affixed to the wall of the buildings overlooking the public garden in Duke Street. Upon it is a representation in *basso relievo* of the head and shoulders of the late Duke. Mr. Taubman was the sculptor. Sir Sidney Waterloo said the company had been prompted to erect the memorial from a feeling of gratitude to the late Duke, who was one of the best great landlords of the Metropolis, and had devoted his influence and great wealth to the promotion of all kinds of philanthropic objects. It was about fifteen or sixteen years ago that he first became connected with the Improved Industrial Dwellings Company, to whom he leased plots of ground greatly below their value for the working people of the district. In this way 773 dwellings had been provided for 4,000 persons. The dwellings were never unoccupied, and were undoubtedly a great convenience to the working classes of the district.

Statues of the late M. Jules Simon, philosopher and statesman, are to be erected in the Place de la Madeleine Paris, and in Lorient, his native city.

A Stained-Glass Window at Mersham Church has been erected to the memory of the late Rev. Frederick Bernard Lockwood, a former rector and canon of Canterbury Cathedral.

Christ's Hospital.—At last week's meeting of the Court of Common Council a report was read from the City Lands Committee in which they stated that they were not prepared to recommend any opposition being offered to the acquisition by St. Bartholomew's Hospital of the land occupied by Christ's Hospital, which would become vacant by the removal of the school to Horsham. The report was adopted.

A Memorial Arch for New York.—The designs of Mr. Ernest Flagg for the New York Naval Arch have been finally approved by the promoters of the undertaking, and a committee has been appointed to raise funds for carrying it into execution. Meanwhile the design is to be submitted to the Municipal Art Commission, whose sanction is necessary before it can be erected. The cost of the monument is now estimated at eleven hundred and thirty thousand dollars.

The Society of Lovers of Old Paris is agitating for the removal of the bronze statue of Napoleon I., by Seurre, from the depôt where it lies at present to one of the museums of Paris. This statue of the Emperor shows him in the well-known greatcoat and *petit chapeau*. It was taken from the top of the Vendôme Column during the Second Empire and replaced by the Cæsarean Napoleon, which was destroyed when the Communists demolished the column thirty years ago.

A Discovery of a Masterpiece has just been made in a convent in the Latin Quartier, formerly the residence of the Comte de Chambrun. It is the work of Clodion, a famous sculptor of the eighteenth century—a bas-relief composed of four great friezes and four lunettes. The Ville de Paris is anxious to acquire possession of the work, but the price demanded is too high, and for the moment negotiations are in abeyance. But there is no danger of harm befalling the sculpture, as it will be well cared for in its present position.

A Monument to Officers and Men of H.M.S. "Powerful" who died in the South African Campaign has been erected in Victoria Park, Portsmouth. The monument is 24ft. high, the bottom stone being of York landing, 6ft. 6in. sq. Then comes a granite dressed base, on the top of which is a moulded base, above this being the die stone, with the inscriptions. This is polished and dressed, as is also the surmounting cap and needle, the latter being 12ft. high. Peterhead granite alone has been used in its construction. The base is 5ft. sq. and 1ft. 7in. deep. The monument was designed by Fleet-Engineer Edwards, of the "Powerful," and the work was executed by Young Bros., of Highland Road, Eastney.

King Alfred's Millenary.—The city of Winchester, in which the representatives of universities and learned societies will shortly assemble, was the capital of King Alfred. The National Home-Reading Union has arranged to hold its summer assembly in Winchester from June 22nd until June 29th, when the members of the assembly will disperse, visiting Athelney or Wantage. During the week lectures will be given by Dean Stubbs, the Bishop of Bristol, Professor Skeat, the Rev. Dugald MacFadyen, Mr. P. H. Wicksteed, Dr. T. J. Lawrence, sometime Deputy Whewell Professor of International Law at Cambridge, the Dean of Winchester on "Winchester Cathedral," Mr. N. C. H. Nisbett on "Wolvesey Castle," Mr. J. E. Marr, F.R.S., Sec. G.S., on "The Application of Geology to Scenery," and others. The last named lecture indicates a secondary purpose of the meeting; namely, the study of the geology and botany of the district, as well as its archæology. The afternoons of the assembly will be devoted to visits to the places and monuments associated with the great king's fame, as well as to the exploration of the memorials of mediæval times with which the district abounds. The assembly is open to all who obtain tickets, price 10s. 6d., from the secretary N.H.R.U., Surrey House, Victoria Embankment, London, W.C.

THE KING AND THE "B. J."

LAST week's catastrophe to "Shamrock II." in the Solent, when His Majesty's life was so seriously imperilled, is a poignant example of the suddenness of accident.

In view of the hazards of everyday life it is clearly necessary for all persons to insure against accidents.

Every reader of THE BUILDERS' JOURNAL should avail himself without delay of the advantages offered by our new Insurance Schemes.

There are **Three Schemes** connected with our Papers, guaranteed by the OCEAN ACCIDENT AND GUARANTEE CORPORATION, LTD., and all readers who have not yet sent for particulars should do so at once.

There are many readers whose names and addresses we do not know, as they subscribe to the Journal through the bookstalls or newsagents. EVERY READER WHO HAS NOT RECEIVED ONE OF OUR INSURANCES SHOULD WRITE AT ONCE FOR PARTICULARS.

Scheme No. 1 is a free Accident Insurance of **£500.**
FREE.

Scheme No. 2 is an Accident Insurance of **£500,** giving the following additional advantages:
Premium, 1/-
£250 for Permanent Total Disablement.
£2 10s. 0d. per week for Temporary Total Disablement.

Scheme No. 3 is an Accident Insurance of **£1,000,** with these additional advantages:
Ordinary Risks, Premium, £3/-/-
£500 for Permanent Total Disablement.
£6 per week for Temporary Total Disablement.
Hazardous Risks, Premium, £3/10/-
£1 10s. per week for Temporary Partial Disablement.
£30 Annuity.
£3 per week during confinement from such illnesses as Diabetes, Scarlet Fever, Carbuncle, &c., &c.

The Condition attached to these Schemes is that they only apply to Annual Subscribers.

If these schemes interest you, write for full particulars to

BUILDERS' JOURNAL,
EFFINGHAM HOUSE, ARUNDEL ST.,
STRAND, W.C.

Masters and Men.

The Masons and Builders Association of New York has locked out between 15,000 and 20,000 bricklayers owing to differences which have arisen.

The Penrhyn Quarry Dispute.—The following notice, dated May 20th, has been issued by the manager of the Penrhyn Quarry: "The Penrhyn Quarry will be open on Tuesday, June 11th, to all the late employees who have applied for work and have been accepted. As announced in February last, the discipline rules have been relaxed, and a new rule has been drawn up and agreed upon which will practically give a half-holiday on the last day of every month; in other respects the quarry rules remain as before. (The new rules referred to are given below.) During the next fortnight (*i.e.*, not later than Tuesday, June 4th) I am prepared to receive further applications from late employees (except boys) who wish to return to work. All applicants must give their former quarry number and 'ponc,' also full name and address. Applications from 'boys' for readmission to the quarry cannot be considered until at least a fortnight after the commencement of work by the men. In order to enforce the law concerning intimidation or annoyance by violence or otherwise (under the Conspiracy and Protection Act) efficient police protection has been promised by the chief constable, Colonel Ruck.—E. A. YOUNG." The new rules referred to above are: Discipline.—All punishments will be by "suspension" or dismissal. For instance, if a workman comes late (except through sickness or sudden case of great emergency) he will the first time be "cautioned," the second time suspended quarter day, third offence half day; but persistent offenders would be more seriously punished or dismissed. Settling Day.—On the last Tuesday in each quarry month the employees after giving up their slates, settling their accounts and arranging their bargains for the coming month will be free to leave the quarry if they wish for the remainder of the day.

Strikes in Italy.—At Milan the masons, bricklayers and men employed in all branches of the building trade have gone out on strike. At Milan they number at least 12,000. An important feature of the strike is the organisation of the men, who have divided themselves, military fashion, into detachments, each of which has a commander and several lieutenants. The causes of the strike are not very clear, and it seems to be rather a rehearsal for some bigger event than a genuine demand for higher wages or shorter hours. This supposition is also borne out by the military organisation.

Trade and Craft.

The Manufacture of "Teon" Belting.—New plant for the manufacture of "Teon" belting, a speciality of the firm of Fleming, Birkby & Goodall, Ltd., West Grove Mill, Halifax, was inaugurated recently at the branch works at Fleetwood. The principal part of the new installation is a calender 22 tons in weight, with 22in. rollers of chilled steel, and formidable diagonally-cogged wheels. The rollers stretch and squeeze the specially woven fabric which constitutes the basis of the belt, composition being at the same time frictioned into the cloth, the work being done at the rate of three yards per minute. The speciality of "Teon" is this secret cement, which first undergoes adequate pounding in an adjoining press, and is then transferred to the calender. Moisture to soften the compo during the process is derived from the hollowed rollers, which may be charged with either steam or water. The pressure in the calender is such that an inch plank of deal is reduced in thickness to a quarter. The composition used in "Teon" is thus squeezed or "keyed" into the very fibres of the cloth, and there is no chance of peeling it off after the operation. Other processes are necessary before the finished belting is obtained. The cloth, now saturated with the composition, is built up in plies, which are folded and sewn and the whole cemented by a patent process under a pressure of 2,000lb. per square inch and in a suitably high temperature. The sewing is done by means of a trio of Singer's machines, running tandem fashion—a device for saving time and increasing output. The belting is next painted and varnished, and then is ready for the market. In one part of the Fleetwood establishment belting for motor-driving and severer strains is machine-stitched with copper wire. A demonstration of tests on "Teon" and competitive belts was also given. The makers claim for "Teon" that it has an efficacy and durability not found in any other belt on the British market, being unaffected in variable, extreme and chemically-charged atmospheres and abnormal conditions generally, which have been the bane of belt driving. Pieces of "Teon" had been for twenty-four hours soaked in strong solutions of caustic soda, of ammonia, in acids and in lubricating oil. The effect on the cementing material was inappreciable, and there was no separation of the fabric whatever. Samples were also immersed in boiling water, and a pipe from the boiler poured in a 50lb. pressure of steam. Two minutes' exposure to this trial told a tale on two of the samples, their cement becoming soft and sticky, and the folds of the material opening with very little persuasion; on the other hand, "Teon" was not in the least affected. Other pieces were exposed to a current of live steam. Again "Teon" came out unimpaired, whereas the composite covering of another belting actually caught fire. Similar severe scientific tests with the belting have been made by Messrs. Stanger & Blount, Westminster, and by Mr. W. Ackroyd, F.I.C., the Halifax analyst, and these tests showed the belt to be capable of resisting the action of dry heat up to 230 degs. Fahr., and of steam up to 200 degs. Fahr.

KELVEDON (ESSEX).—Accepted for the erection of eight cottages in concrete, for Miss Docwra. Messrs. Clare & Ross, architects, Chelmsford and London:—

Clare Bros., 38 Borthwick Road, Stratford	£1,668

LEAMINGTON.—Accepted for the erection of a house, for Mr. R. D. Sykes. Mr. H. O. Cresswell, architect, 17 Buckingham Street, Strand, W.C.:—

John Barnsley & Sons, Birmingham	£9,888

LEISTON-CUM-SIZEWELL (SUFFOLK).—For works of sewerage and sewage disposal. Mr. Henry Miller, M.I.C.E., engineer, Ipswich:—

S. Saunders, Earl's Court Square, London	£3,827 0 0
J. Moran & Son, Dovercourt Road, Harwich	3,612 0 0
J. S. Smith, 24 City Road, Norwich	3,549 0 0
W. Manders, Leyton	3,466 10 6
Cutler, Haywood & Co., Lowestoft	3,462 0 0
G. Bell, Tottenham	3,137 0 0
J. Coker, Halling, Rochester	3,125 13 4
J. O. Trueman, Swanley	2,992 0 0
G. Burgoyne & Sons, Ipswich	2,919 1 2
G. Double, Ipswick	2,810 10 0
Grimwood & Sons,* Ipswich	2,597 0 0

* Accepted.

LONDON.—For road repair and drainage works at the Park Hospital, for the Metropolitan Asylums Board:—

J. Weston & Sons, Octavius Street, Deptford, S.E.	£2,095 5 6
T. Adams, Green Lanes Goods Station, Wood Green, N.	1,705 2 0
W. Pearce, David's Road, Forest Hill, S.E.	1,664 9 7
Fry Bros., Lion Wharf, Greenwich, S.E.	1,532 18 0
Weston & Hale, 43 Tubbs Road, Harlesden, N.W.	1,366 18 7
J. Mowlem & Co., Grosvenor Wharf, Westminster, S.W.	1,301 0 0
H. Bentham & Co., Telford Avenue, Streatham Hill, S.W.	1,147 0 0
R. Ballard, Limited,* Child's Hill, N.W.	1,097 0 0

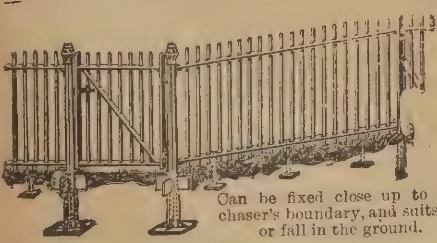
* Accepted.

LUTON.—For the erection of children's homes in the Dunstable Road, Luton, for the Guardians. Mr. B. B. Franklin, architect, 21 Market Hill, Luton:—

J. Saunders & Son, Duke Street	£3,440 0 0
D. Parkins, High Town Road	3,186 0 0
E. Foster, 13 Bury Park Road	2,985 17 9
Mallett & Wood, Melson Street	2,973 0 0
Phillips & Blake, Harpenden, R.S.O.	2,900 0 0
G. W. Dunham,* Guildford Street	2,883 0 0
J. W. Smith, Charles Street, Small Heath, Birmingham	2,877 0 0

[Rest of Luton.]

* Accepted.



Can be fixed close up to Purchaser's boundary, and suits rise or fall in the ground.

BAYLISS, JONES & BAYLISS'

NEW PATENT
SELF-ADJUSTING ROUND-BAR
RAILING (No. 2740),

Is, we believe, the cheapest in the market.

ILLUSTRATED CATALOGUE OF ALL KINDS OF HURDLES, FENCING, GATES, &c., FREE.
VICTORIA WORKS, WOLVERHAMPTON.

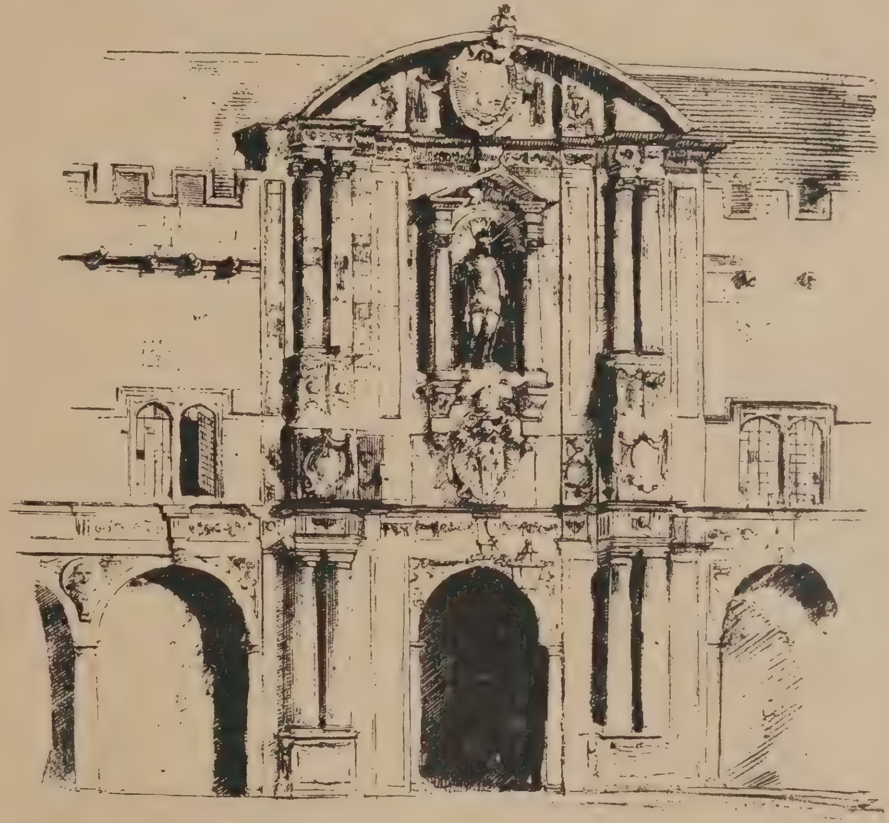
An Architectural Causerie.

The late Mr. Brydon. IT is a melancholy fact that the late Mr. J. M. Brydon should have died just when his huge building for the Local Government Board and Education Department was about to take shape and rise from its vast site in Whitehall—a building to which he devoted so much time, so much energy, so much attention. Remembering this, and recollecting also that Mr. William Young died when his new War Office was almost in a similar condition, one pauses to think of the responsibility and worry entailed by those who have charge of great works. Numerous instances could be mentioned—such as that of Street and the Law Courts—of architects whose lives have been brought to a hurried close by reason of the anxieties of their labours. This is especially the cost of greatness. The care appurtenant to the erection of a large governmental building like that of Mr. Brydon needs no emphasis, and one only wonders that the men can withstand the strain for so long. Mr. Brydon will be greatly missed. He was a kindly gentleman, and those who saw him in the chair at Institute meetings will recall the complaisant manner in which he carried out his duties. He was dignified without being austere, courteous and attentive to everyone's questions, and able to express his opinions clearly and convincingly. Longfellow's lines are very apt:

> "All are architects of Fate,
> Working in these walls of Time;
> Some with massive deeds and great,
> Some with ornaments of rhyme."

Edison and Building. MR. EDISON is a man surrounded by a journalistic halo of glory, and this is the whole explanation of the ridiculous accounts which reach us here of his inventions. We are informed by telegram what wonders are to be effected by his latest devices, and how old methods are to be entirely revolutionised. The latest information about him affects the building industry. The New York telegram runs as follows: "Mr. Edison is reported to have said in an interview that he has invented an improved cement. All buildings in future are to be made of this cement. An iron framework is put up, the cement poured in, the roof thrown on, and in three or four days the house is fit for habitation. Mr. Edison says the cost will be insignificant and rents will be reduced enormously." This is delightfully naïve. We should be much interested to see a building erected in the manner described. Moreover, the confidence which asserts that this cement is to be the universal building material of the future is indeed worthy of an American journalist. We have read accounts of Mr. Edison's inventions before, and we shall wait before we believe in such a report as this one, which, however, is typical of what the American inflicts upon us. Mr. Edison may have invented a new cement, like other persons; also, he may not; but in any case it is not likely to possess the characteristics stated. Newspapers ought not to print such misguiding rubbish, for it is harmful to the public and damages Mr. Edison's reputation.

Stealing Houses. ONE of the most remarkably audacious thefts of building materials we have ever heard of is reported on p. 342 of this issue. The thief was a man named Richards and his speciality was houses. It will be seen how he coolly selected a house which was unoccupied and without the slightest authority enclosed it with a hoarding and razed it to the ground; he then removed the materials and sold them. A man who could carry out such a project is worthy of better things. Richards is now in the employ of the Government for three years.



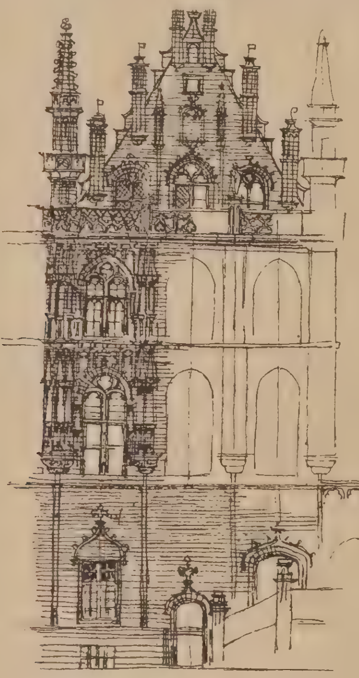
GATEWAY, ST. JOHN'S COLLEGE, OXFORD.

Lady Architects. A POPULAR ladies' magazine has printed an article on "Architecture as a Possible Career for Girls," the whole theme of which resolves itself into "what can be done by a girl merely giving her help in the designing of a house." We are told that people who build houses fail to do so in the best possible way because "they have to make so much percentage every year on the money expended, or the house has been built to sell because of its stained-glass windows." The blame, however, is not laid on the builder's shoulders but on those who buy and live in these houses. The writer deplores the fact that girls do not learn the geography of the perfect house side by side with their French verbs and arithmetic. "They attend lectures on architecture, perhaps are learned in Gothic and Renaissance periods, revel in transepts, and simply adore a gargoyle; but the fact of a cistern being a vital part of their own house appals them, and complaints from the cook on the question of a kitchen sink terrify or merely disgust." The writer then devotes almost all her remaining space to describing the plans of a house "drawn by an expert" which apparently meets all requirements. One of its chief features is a basement portioned off for a wash-house, laundry, heating apparatus, workshop, coal-cellar and dust depository, fitted with lifts and shoots. The expert, however, has arranged his walls in a curious manner, and there is no arrow to show what aspects the various rooms face. Leaving however these particular plans, it is well to consider the main subject. The writer says: "Girls are not welcomed professionally as members of an architectural office staff, and as yet few of them have had the courage to begin work on their own account. The old cry that women will not be able to find workmen to obey them, I refuse to believe in; for, within the writing of this article, I have seen a West-End London house in the hands of two lady architects for alterations, and discovered how efficiently measurers and tradesmen worked under their direction. In America, women are already recognised as capable architects. In Austria, quite recently, a Fräulein Erska Paulas received a valuable Government commission to erect, at Bistritz, a residence for the Official Forest Commissioners. In our own country, to a girl, there are no obstacles of training in her way. The Schools of Art are open to her, and as an articled draughtswoman she may receive an office experience. The Royal Institute of Architects allows women to qualify as Associates, and already two girls have successfully passed their examinations." Lastly, the writer advocates girl consulting-architects in connection with dwellings for the working classes. Now these matters, even though they appear in a ladies' paper, are worthy of the attention of practising architects. The idea at first seems strange, and is apt to be either decried or pooh-poohed, but when one looks around and sees what a number of women are engaged in the business and artistic pursuits of to-day the notion gains credence. To say that, because there are lady artists, so there may be lady architects is not perfectly justifiable, because no such practical duties are imposed on the former as on the latter, but that architecture as a profession for women will be largely adopted in the future seems highly probable, though the difficulties to be encountered will be many — not to say embarrassing in some circumstances.

FLANDERS—COMMERCE AND ARCHITECTURE—I.*

By JAMES LOCHHEAD, A.R.I.B.A.

"TRAVEL in the younger sort," says Bacon, "is a part of education," and to the architectural student the education, especially in the region of foreign travel to which we may presume Bacon refers, is or should be at once objective and subjective. The monuments of all countries, and more particularly those of antiquity, even if only on account of association, other than as evidences of intrinsic beauty produced by a bygone race, yield an amount of inductive information, and convey suggestion born of reminiscence even to the ordinary beholder who, if only in a superficial manner, analyzes, perhaps unconsciously, their import, and sees beyond and behind the emotions and story they betray, receiving his impressions in a general sense. He compares the past and present conditions relative to the buildings, their environment and their history, and creates an association of ideas which, like a meteor, revolve round the mere eye of memory, without encountering the atmosphere of reason and underlying principle, in which they would burst forth and illuminate the perceptions with the fuller light of truth and suggestion, which enables the architectural mind to "read, mark, and inwardly digest" the more ably. The man with an appreciation of architecture can, by virtue of his training, his knowledge of art history and his conception of the beautiful, realise some delights and derive some education from the study of monuments which are almost obscure to the ordinary observer.



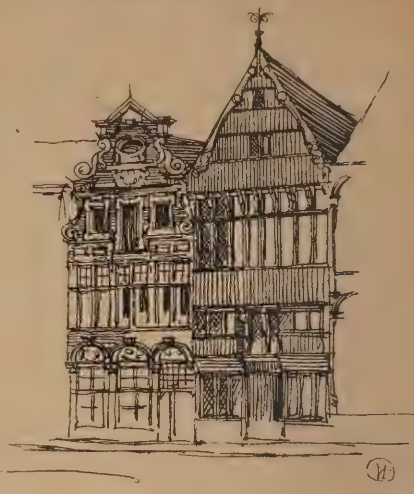
THE HOTEL DE VILLE, OUDENARDE.

What I mean by the educational results of travel will, I hope, appear clear in the sequel, and may not be enlarged upon here; but, meantime, I shall remark upon the means to the end, the method which assists the reason to analyse the better, the use of sketching, whether of the elaborate Pugin studentship type or mere wayside jottings and notes, and, in a less personal degree, photography. Sketching, by itself, is undoubtedly one of the most invaluable means of training eye, hand, mind and reason, but to my idea it is apt to develop too much into a means and create a desire for the purpose of amassing a collection of architectural features, "bits" or details, which one may consult and reproduce according as opportunity occurs, in part or in whole, on our buildings. To my mind there is something to be gained beyond this, and in associating the combination of circumstances, facts and history, together with the mere tangible expression which we wish to convey to paper, one may derive in a subjective way more real, if not also moral, education and ultimate good. "Architecture," says Banister Fletcher, in his history, "has often been too much isolated from its surroundings, and the main points of the physical geography, social progress, and historical development of each country require to be understood by those who would study and comprehend its particular style," and although there may be "some disproportion between our studies and our performances," we shall never understand the separate parts of the subject unless by a thorough, reasonable, and discerning study of the whole. The larger the buildings (and may I venture to say more particularly ancient buildings), and the more ambitious the study, the better; we get the architecture at its best upon which the most skilled workmen were employed, upon which the aspirations of the people were displayed, and in which the character of the nation was best reflected and most apparent for our edification.

I said at the commencement "foreign travel," and I did so advisedly, and with no attempt at disparagement of our own country as a field for study; only, in the latter case, the conditions and history which begat our national monuments are so well known, or should be, or so inadequately taken into account, that too much fancied familiarity has almost bred contempt for the considerations to be attached to the buildings. On the other hand, where such inherent, if badly applied, knowledge of facts and circumstances does not obtain such a hold on us, the ardent student is more likely to associate all the impressions and arrange them into such an order as will produce a definite result and effect upon his architectural reasoning, and cause a selection and rejection.

When this reasoning process of study is expended upon one particular phase of architecture, as it might evolve under certain distinctly marked influences and conditions racial, local, and political, it is more easy to discern the end in view than when varied conditions and motives existed.

Belgium, or rather Flanders, I venture to affirm, almost maintains a "splendid isolation" in the former respect, for it contains within itself an architecture which, if not original, is at least peculiarly expressive of the conditions which influenced it in its halcyon days of commercial and industrial prosperity. In order to reflect to the best of my ability the impressions which were produced by a recent tour, when, one of a party of eight with a united aim, I traversed the principal cities and towns of this famous dominion of Hanseatic sway, and attempted to study the elements of their glorious remains, it will be judicious to present them in the order in which they developed, by a series of impressions general and pictorial at first, architectural, comparative and associative afterwards, and at length and not least important, reflective.

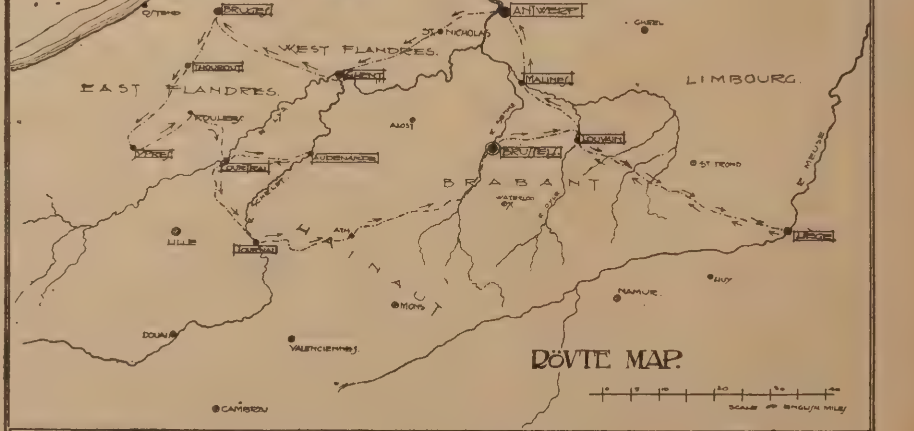


OLD HOUSES, MALINES.

As a general and pictorial impression, I shall review briefly the places visited, and neglecting the order of things as they appear *en route* on the map, roughly divide them into two classes with respect to that element which enters so largely into their being, their relatively past and present industrial prosperity—that is, the places "with a past" of great commercial and architectural activity contrasted with present lethargy, and those with a glorious past combined with a present activity—two possible divisions which impress one almost before anything else.

The former group may be said to contain most that is of interest, and comprises Ghent, Bruges, Ypres, Oudenarde and Malines; while the latter, including Antwerp, Brussels, Courtrai, Tournai, Louvain and Liège, are by comparison only of less interest.

Ghent—that is, the early portion—is essentially a place with a past, and it does not require the hackneyed expressions of a guide book to arouse the idea that it was once an important municipality, and one of the busy haunts of men who raised it to its once proud position of the chief manufacturing city in Europe; for its buildings bear upon them the impress of a departed glory, and a walk along its rivers and canals, once busy and active, now sluggish and almost deserted, on the banks of which, as will be understood, the story of its decline and fall is plainly written, but serve to confirm these sentiments, the proud gables now marking the scene of a changed life and telling the story of their ancient creators. To a very great extent Bruges partakes of this feeling; but the artistic joys and pleasures which exist in this glorious old town—as Longfellow puts it, "In the ancient town of Bruges, in the quaint old Flemish city"—a town which Grant Allen said was more interesting than any one thing in it, the delights of its quaint buildings "beside the still waters," apart from its municipal glories and the other internal evidences of its ancient wealth, destroy for the time all regrets, and subdue all moralisings on the transient nature of things material. It is a place full of continual and kaleidoscopic charm, and a very Eldorado for the artist—as one of our party expressed himself



---

* A paper read before the Philosophical Society of Glasgow (Architectural Section) on November 26th, 1900.

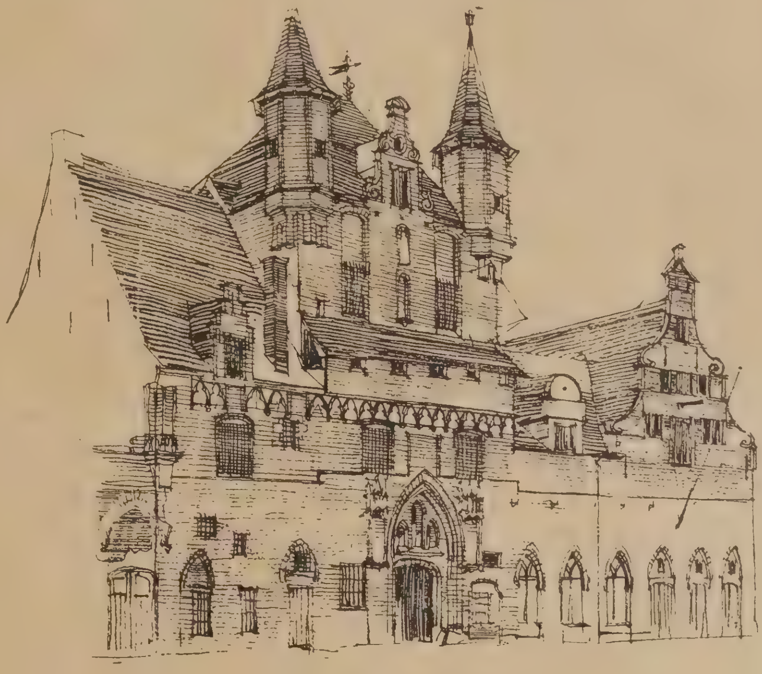
"there's no wonder they made painters here"! So much is one impressed with the life, variety and charm of Bruges, that the change to such sleepy and lethargic old places as Ypres and Oudenarde, and especially the former, that the lively chimes alone, "the melodious bells among the spires," arouse one from an inert attitude induced by the very oppression of the stately Cloth Hall whose silent eloquence fails even to rouse one out of the depths of pity and regret. This feeling finds an echo in the almost deserted squares of Oudenarde, only made vivacious to the mind's eye by the influence of the playful Hotel de Ville, or the picturesque banks of the Scheldt on which it stands, "remote, unfriended melancholy, slow," its fine church tower standing like a sentinel over the dreary and monotonous jumble of modern dwellings, which only serve to throw it out into bolder relief and majesty.

Only at Malines of these "departed shades" does one realise a little of the mediæval effect of some business activity, because although sleepy the town by virtue of its special industry permits the privilege of such an imagination, street, square and river alike being redolent of the industrious citizen, who, in the ofttimes quaint costume and noisy "sabots," assists the equally quaint and interesting structures in producing a peculiarly fascinating and old-world appearance. The contrast, however, architecturally and locally, betwixt such places as these and busy hives like Antwerp or Brussels or Liège is most marked. Antwerp, a thriving seaport and a tangled skein of animated streets, seems literally to hum around the base of its great cathedral, while here and there a stray gable of quaint outline, discovered in the midst of more assertive surroundings, betrays its connection with a bygone day. This old-world repose amid scenes and surroundings born of a later day is perhaps more manifest at Brussels, whose Grand Place with its peculiar and romantic guild houses standing "cheek by jowl" with its majestic Hotel de Ville, its pictorial Maison du Roi, and all that go to form what has been termed "the finest square in Europe," remaining in calm and revered antiquity—all went to mitigate the feelings of disappointment we were impelled to entertain with regard to Brussels as a whole, and which we exhibited by a hasty departure. Less disappointment results, probably on account of fewer expectations, at Courtrai, with its solitary belfry, left standing in the heart of a thriving population beside the lazy waters of the Lys meandering slowly in contrast to the town's industry; at Tournai, whose grand Romanesque cathedral dominates the city; and at Liège, which, reminiscent of Sir Walter Scott and the fortunes of Quentin Durward, maintains its Bishop's Palace there made famous, and a few less important testimonies of its ancient importance, and that amid a busy and active community. Louvain alone of these quasi-ancient and modern places rewards the architect to satisfaction and whether it be its Hotel de Ville, its churches, or its university—and there is much else of interest and excellence in the town—it tends to atone for the comparative architectural poverty of those cities and towns which constitute modern Belgium. I say "poverty" because the modern buildings for the most part exhibit a falling from the high estate attained by the erections of the past, although now under no less prosperous conditions. It is this that makes one marvel and involuntarily decide that a change must have enveloped the nation, the excellences of the evidences of whose commercial splendour have thus degenerated. History aids in suggesting the cause, and, as a writer remarks, is "one of those silent factors in the world's life, one of those iron keys which opens massive doors into still chambers, wherein strong men may look and wise men learn."

Flemish history fortunately possesses for our reflective purpose some salient epochs and features which influence the position and interests of the people very substantially and affect particularly its art. The social history of all nations is influenced by some marked epoch or power which moves its thought to its ultimate if temporary progress, and the history of Flanders is writ large with two great factors inseparably connected, those of independence and commerce, the latter a power, as Motley says, "the mother of Netherland freedom, and eventually its destroyer," a "good custom which corrupts the world."

The truth of Bacon's philosophy has, perhaps, no better proof than in the present case. "In the youth of a state," he writes, "arms do flourish; in the middle age of a state, learning, and then both of them together for a time; in the declining age of a state, mechanical arts and merchandise."

After the death of Charlemagne, the empire which he held together during his lifetime fell to pieces, and in the chaos which ensued the realm was divided, subdivided, and at times partially re-united like a family farm among incompetent monarchs, into shreds and patches of sovereignty. In this condition a series of forces acted upon the movements of society, and in the order of those activities which constitute human life—that which ministers to self-preservation first manifested itself, and "the power of iron" asserted and exerted itself in a struggle for supremacy between the isolated states. This was succeeded by the force clerical, the power of priesthood, "the might of educated mind measured against brute violence," which became as potent as the sword, but less so than the power of gold or the force of commerce, which came next, and, developing itself more slowly, changed insensibly and miraculously the aspect of society.



THE HALLES, MALINES.

The genius of Liberty conducted by the spirit of Commerce descended upon the alienated states, and the counts, recognising the spirit of self-government, stimulated by this isolation and the prosperity of the country, anxious to increase their own importance, granted privileges to their communities, who, thus formed into half-independent states under their own counts, organised and inspired with the breath of civic life, assumed the appearance of prosperous republics.

The Hanseatic League, that trades-union of the thirteenth to the fourteenth centuries which existed in North Germany and Flanders, and had for its device "Freedom for the common merchant at home and abroad," contributed by its formation of trade guilds, together with the influences and passions at work within the communities, to the production of those evidences of prosperity and national life which are portrayed in the architecture of Flanders, and brought the influence—artistic and social—of various countries into contact. These then were the historical influences, thus very broadly expressed, which marked the architectural expression of Flanders.

It is difficult to gain an idea of the full extent and nature of mediæval trade, but this was far more rich and varied than we suppose; and all the evidences we have of the wealth and luxury are in the remaining monuments of the time, and, happily, these are plentiful.

We know by these and other artistic treasures that art flourished, but it is the art of a purely commercial people, for, as exhibited in the pictures of the times, to quote Grant Allen, for the most part "they are portraits of solid and successful merchants, or the devotional works which a merchant donor presented to the patron saint of his town or business."

The architecture, on the same principle, is a strictly municipal architecture, expressive of the communities themselves. The belfries are primarily a mark of independence, and a means of summoning the citizens to arms, while the town halls presided over by the councillors chiefly chosen from the leading merchants, as a meeting place of the burghers, represent the wants of the communities themselves.

These were the centre of all national life, the market-place was built round them, around were the chief shops, and chief among these the cloth halls where the Flemish cloth and linen, the staple manufacture, found buyers from every European market, while the guild houses of the different trades, whose interests were protected by the League, afforded means of inter-communication and conference, where

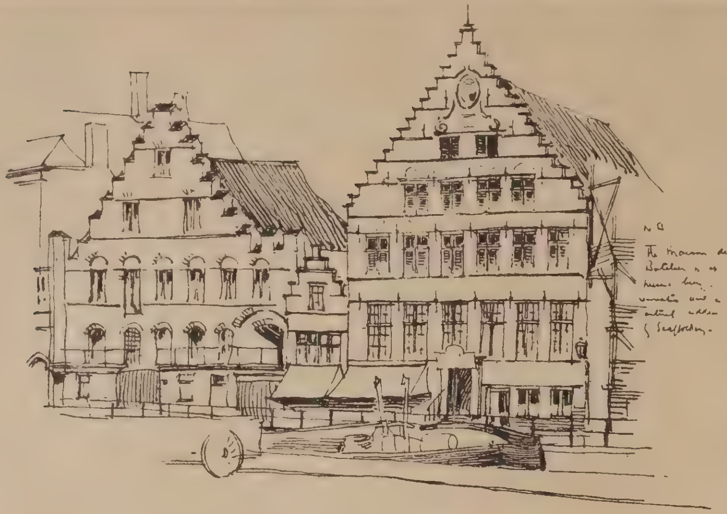
> "Lombard and Venetian merchants with rich-laden
> argosies,
> Ministers from twenty nations,"

might assemble and possibly reside at times in the lordly town mansions of the opulent burghers. These "town halls and markets," says Ferguson, "and the residences of her burghers, still display a degree of taste and elegance unsurpassed by anything of the age, and remain to this day the best index of the wealth and independence of the communities to which they belonged."

In addition to this, and apart from them as evidences of commerce, the churches and religious buildings, many of which survive to this day, amid surroundings to which they have grown strange, speak more eloquently of the Hansas' might than piles of old parchment records, as they point to the church as the one converging point of ideal life.

Following this order, the architecture as a direct outcome of the commercial spirit, and especially the civil and domestic architecture in which Ferguson declares "Belgium surpasses all the rest of Europe put together," can be well illustrated in the sequence which the same authority adopts, namely of belfries, town halls, guild halls and churches.

As already stated, the belfry was the earliest architectural expression of newly-acquired freedom, and the right of having a bell was one of the first privileges granted in old charters, not only as a symbol of power, but as the instrument for calling the communities together either with arms in their hands to defend their walls, to repress internal tumults, or for the election



GUILD HOUSES, GHENT.

of magistrates and deliberation on the affairs of the commonwealth.

The tower was generally the record office of the city, the place where the charters or more important deeds were preserved.

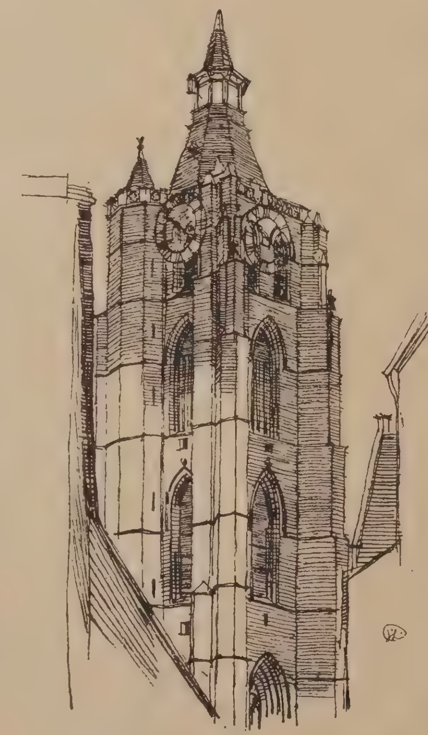
Now, the original use has ceased to be, and the sole remaining joys consist in the pleasures of a contemplation of their ofttimes graceful proportions, and listening, like Longfellow at Bruges,

> "To the chimes that through the night
> Rang their changes from the belfry
> Of that quaint old Flemish city."

The town halls present a "glorious company" of rich and expressive buildings existing to this day, and that in a splendid and carefully ordered preservation; they reflect, as none else of the edifices do, the wealth and luxury of Flanders. True, a similarity of style pervades them, and a redundancy of ornament might be laid to their charge, but the result is peculiarly satisfying. In some parts the detail is coarse, but the application of ornament for the most part is in such good taste that we forget to criticise the defects; and even if "the crowd of statues, in whose folded sleeves birds build their nests," are often modern or hard, and not always in perfect harmony with a civic building, they serve to add life and additional interest. Where they exist in the same cities the trade or cloth halls bear a well-marked distinction from the town halls, being for the most part in keeping with their purpose, less ornate, and more reposeful and reticent in effect; and, as if in direct courtesy to the various commercial peoples with whom trade was conducted, in some cases they bear unmistakable evidence of foreign architectural influence. The Cloth Hall at Ypres is a building which all of us know by repute, and to those who see it for the first time the eulogies passed upon it are thoroughly appreciated. It seems to rise at you, so to speak, and assert itself, while its mass, though dominating everything in the neighbourhood, even to the adjoining cathedral of St. Martin, is not unduly aggressive. The smaller hall at Bruges, incorporated with the belfry, with its evidence of Italian influence, the quaintly picturesque building at Malines, and the over-restored one at Ghent, all exhibit elements of architectural expression so lucid that he who runs may read. It is unfortunate, on the other hand, that the interiors are as uninteresting as the exteriors are instructive, and on this account a certain amount of architectural aim is lacking.

Like the cloth halls, the guild halls, or meeting places of the various trade guilds or associations of merchants, are at once conspicuous and interesting, even withal the "base purpose" to which they have in some cases descended, and left them, if not in ruins, in the hands of vandals. It was however satisfactory, although our misfortune in one respect, to see the beautiful House of the Skippers at Ghent in course of restoration—a process, let us hope, which stopped at the proper stage, and did not proceed to the extent of gilding which has spoiled the otherwise interesting facades of some other guild houses. In the later Renaissance work these houses exhibited an undesirable amount of bizarre and overlaid decoration, as at Brussels, only relieved by the evident desire to mark their individuality, a purpose accomplished in some cases in a very grotesque manner, hardly worthy of emulation or even admiration. Invariably these buildings were, to use a Scotticism, "gable enders," that sensible architectural means of utilising limited space; and while they bear no special indication—save, perhaps, in the one instance at Brussels—of the particular trade on whose interests they were erected, they bear on the face of them evidence of being something more than mere habitations. Their peculiarly Flemish gable outline, and, where situation and environment permitted, their picturesque grouping, testify to the artistic taste as well as the considerate unselfishness of the builders; for if they had proceeded on the merely utilitarian principle nowadays too prevalent, an amount of selfish obtrusion would have suppressed the joy of beholding thought and care bestowed on others in the erection of a "thing of beauty" for themselves.

No less interesting and expressive are the private houses of the traders or principal tradesmen; and from the Maison du Roi down to the humble or aspiring merchant's domicile the abodes are not over suggestive of wealthy magnates, while each displays that mark of individuality and distinction the lack of which too often robs domestic work of the interest which it is essentially capable of affording. The fact of these dwellings being existent in the towns, close by and identified with the businesses which constituted their owners' interests in life, contributes to the pervading sentiment as equally well expressed in the places of business themselves. Fronts of unique and quaint design constantly meet the eye, in few cases obtruding themselves in the way which vulgar or over-ornamented buildings never fail to do. Although hardly rising to the grade of specimens of fine art, when grouped together in the narrow winding streets, or along the banks of the canals, the result is so varied and charming that we are inclined to ascribe to them more intrinsic beauty than they really possess as individual designs. Most of them are of brick; and using the brick undisguisedly, and depending wholly on such forms as could be given to the material, they never offend our taste by shams, and the endeavour of the citizens to ornament the dwellings externally meets with the success that must always follow such an attempt. When the shapes have been varied to admit Gothic tracery, and the openings fitted ingeniously into them, with the iron-tie ends of clever and appropriate design introduced over the front as construction necessitated, the effect is often extremely pleasant and graceful.



CHURCH OF NOTRE DAME, MALINES.

Apart from the evidences of trade and commerce and prosperity exhibited in these buildings, the evidences of wealth and luxury can also be found in the churches. "Everything that went beyond the immediate practical needs of daily existence, every form of charity, every endeavour after culture, every striving of artistic and scientific activity, had in these days a religious foundation." "In the vast number of cities, towns and villages," remarks Motley, "there has been a vast accumulation of ecclesiastical wealth." That this has been lavished upon the ecclesiastical edifices is proved by the existence of some of the grandest cathedrals and churches that the Middle Ages witnessed. Ferguson declares with his usual emphasis and dogmatism that the Gothic architecture of Belgium is in many points scarcely inferior to that of France. In and at Ypres, with its well-preserved church of St. Martin; Oudenarde, whose massive tower of St. Walburg dominates the surrounding cluster of dwellings; Malines, and its great and dignified cathedral; Antwerp, whose industry throngs at the doors of its picturesque church, and worthy habitation of Flemish art; Brussels, whose cathedral, Durham-like, contemplates the ceaselessness of that gay capital; and, in fact, in every city and town in Belgium there exist proofs that the tendencies of the people did not all run to civic monuments, and their architectural charms are heightened by their being the sacred custodians of paintings, representative of the art of Flanders, whose perfection was only equalled by the enthusiasm of its votaries.

When the great building age had passed, and the great and subtle change produced by the Renaissance had set in—a phase which to a great extent is outside, except for a moral and reflective purpose, the scope of this paper—we see also practically the end of this distinctive architecture. We do not lose sight, however, all at once of the activity and motives of the people, for, as if by the result of their previous endeavours, the new phase did not lose that earnestness which characterised the old and the early examples of a transitional and classic architecture, showing a fusion of endeavours and taste in obeying the irresistible demands of the great voice which spoke throughout Europe. If at first these showed to a degree considerable refinement and grasp, here and there displaying an excellent interpretation of the new style, the internal canker of the states and country gradually manifested itself externally by a slow but sure change to the impoverished architecture of a later day.

In a contemplation of these buildings, then—and an endeavour to penetrate behind and beyond the mere superficial evidences such as I mentioned at the outset might tempt one to put on mental record mere parts of the whole—by reason of certain tangible and attractive merits one's reflections partake of the nature of an evolution, at first touching upon the purely objective impressions without any attempt at association, and gradually working round to and identifying themselves with the subjective impressions intimately connected therewith, which will be found to comprise the ideas artistic, historical and social.

A writer in the BUILDERS' JOURNAL affords a well-expressed clue to such impressions. "It needs," he says, "no subtle power to read from the building the character and temperament of its designer. You may see good sense in the use of material, clearness of head in the simplicity of the plan, a well-balanced mind in the disposition of the masses, courage in the breadth of the wall spaces, imagination in the treatment of a skyline, wit in the contour of a moulding, and humour in an unexpected piece of carving—or miss some or all of these qualities as the case may be."

(To be concluded.)

OBITUARY.

THE LATE MR. BRYDON.

WE very much regret to announce the death of Mr. J. M. Brydon, a vice-president of the Royal Institute of British Architects, which took place, after a short and painful illness, on Saturday morning, May 25th.

Mr. Brydon was born in 1840 at Dunfermline, and there he received his education. At the age of sixteen he went to Liverpool to enter upon an architect's career. He then served under the well-known architects Mr. Bryce, of Edinburgh, and Mr. Campbell Douglass, of Glasgow, and finally he joined the staff of Messrs. Shaw & Nesfield, London. When he felt that the time had come to start professionally in his own name he devoted himself at first to the designing of furniture. But this sphere speedily proved too narrow for his powers, and he found further scope in domestic architecture. Mention may be made in this connection of the country house "Lewins" which he built for Mr. Joseph Robinson, in Kent, and of the extensive alterations to the Château of Buillon, near Besançon, the country seat of the famous artist, M. James Tissot. It was, however, in the design and construction of public buildings that Mr. Brydon excelled and on which his reputation chiefly rested. He was an ardent student and exponent of classic traditions in architecture, and paid a number of visits to Italy with a view to extending his knowledge in this direction. The first works that brought him into special notice were the library, the polytechnic, and the additions to the town hall of Chelsea. His name is prominently associated with the town of Bath, for which he built its guildhall, its Victorian Art Gallery, its technical schools; and the extensions of the pump room. Mr. Brydon also restored the ancient Roman baths there, and by his sympathetic and masterly treatment not only incorporated all that was possible of the ruins, but imparted an air of antique dignity to the new work that has called forth great praise. The work in Bath occupied him about eight years. Other public buildings of his are the women's hospital in Euston Road, the medical schools for women, Hunter Street, and the hospital for stone, Henrietta Street, Covent Garden.

The great work in which Mr. Brydon was engaged at the time of his death was the construction of the new public offices for the Local Government Board and Education Department in Whitehall. He was selected for this important task out of a number of leading architects whose names were submitted to the Government by the Royal Institute three years ago. As yet only the foundations have been laid, so that the guiding mind has been removed just when it had begun really to grapple with the vast undertaking. After being chosen to construct these Government buildings, Mr. Brydon was selected to participate in the limited competition for the rebuilding of the Old Bailey.

Mr. Brydon had been on the council of the Royal Institute of British Architects for a number of years and took a leading part in the work of the Institute; and he was a learned and enthusiastic member of the Art Standing Committee. Although a very busy man he found time to read many papers both at the Institute and elsewhere. He was a man of wide interests and strong opinion, expressed always with geniality and humour, a good talker, and a very pleasant stimulating companion. He will be greatly missed both in the profession generally and in the councils of the Institute. He was buried at Highgate Cemetery on Wednesday last. In the issue of the BUILDERS' JOURNAL for March 12th, 1895, appeared a "Men who Build" article dealing with Mr. Brydon's work.

GABLE ENDS, BRUGES.

THE WONDERFUL PALACE OF KNOSSOS.

FRESH DISCOVERIES.

IN our issue for November 7th, 1900, accounts were given of the wonderful discoveries made in Crete by the well-known archæologists, Mr. A. T. Evans and Mr. D. G. Hogarth. Mr. Evans has now made public through the medium of the "Times" some particulars of fresh discoveries in the Palace of Knossos. He says:—

Thanks to the liberal contributions received from the Cretan Exploration Fund, it has been possible for me to resume the excavation of the great prehistoric building of Knossos—the true "Labyrinth" of ancient tradition—on an adequate scale. The season's work is now so far advanced that a short summary of the results—in many respects not inferior to last year's discoveries—may be of general interest. It is now evident that the palace is of even vaster extent than could have been foreseen from the long lines of outer walls already brought to light. The great entrance court takes an almost unlimited extension to the west. It must have been at once a palace court and the *Agora* of the "broad" Homeric Knossos. The lofty porch with its twin portals within, the ground-plan of which was already cleared last year, also served a double purpose. The doorway to the left leading direct to the corridor beyond, with its processional frescoes, was a real entrance. That to the right, communicating with a single room, may well have been reserved for royal use, and it is natural to imagine the king here, seated at the gate in the Oriental fashion and giving judgment before the assembled people in the *Agora* beyond.

A Piazza and Baths.
